How to use the MICROPAEDIA

The 12 volumes of the MICROPAEDIA contain tens of thousands of shorter articles on specific persons, places, things, and ideas, arranged in alphabetical order. The MICROPAEDIA can be used as an information resource on its own; and it can function as support for the longer articles in the MACROPAEDIA (to which it refers whenever appropriate). The MICROPAEDIA in turn is supported by references in the INDEX and by the lists of suggested readings in the PROPAEDIA. Finally, the MICROPAEDIA is the portion of the *Encyclopædia Britannica* best suited for the reader who wishes to browse among the countless subjects in all fields of human learning and history in all times and places.

Alphabetization

Entry titles are alphabetized according to the English alphabet, A to Z. All diacritical marks (such as in ö, ð, or ñ) and foreign letters without parallels in English (such as ayin ['] and hamza [']) are ignored in the alphabetization. Apostrophes likewise are ignored. Titles beginning with numbers, such as **1812, War of**, are alphabetized as if the numbers were written out (**Eighteen-twelve, War of**).

Alphabetization proceeds according to the "word-by-word" principle. Thus, **Mount Vernon** precedes **mountain**; any **John** entry precedes **John Henry**, which in turn precedes **Johne's disease**. Any character or string of characters preceding a space, hyphen, or dash is treated as a word and alphabetized accordingly. Thus, **De Broglie** precedes **debenture**, and **jack-o'-lantern** precedes **jackal**. Titles with identical spellings are arranged in the following order: (1) persons, (2) places, (3) things.

For many rulers and titled nobility, chronological order, as well as alphabetical order, governs placement. Rulers of the same given name (e.g., **William**) may be grouped together, separate from other entries, and indicated by the symbol •. They may be subgrouped alphabetically by country and, within each country, arranged chronologically (**William I, William II**, etc.). Nobility or peers of the same titled name (e.g., **Essex, EARLS OF**) are similarly grouped together, separate from other entries; they are indicated by the symbol • and arranged chronologically.

Places with identical names are arranged in the alphabetical order of the countries where they are located. Identical place-names in the same country are alphabetized according to the alphabetical order of the state, province, or other political subdivision where they are found.

Entry arrangement

The titles of entries are arranged according to the forms commonly found in indexes and dictionaries, with some special conventions.

Entry titles for certain physical features, institutions, structures, events, and concepts are ordinarily inverted to place the substantive word first. Thus, the Bay of Bengal is entered as **Bengal, Bay of**; the Bank of England as **England, Bank of**; the Tower of London as **London, Tower of**; the Siege of Vienna as **Vienna, Siege of**; and the balance of power as **power, balance of**. If the name of a physical feature, institution, structure, event, or concept has two or more descriptors, it is entered under the descriptor appearing first. Thus, the Episcopal Church in Scotland is entered as **Episcopal Church in Scotland** (not **Scotland, Episcopal Church in**); the Leaning Tower of Pisa as **Leaning Tower of Pisa**; and the kinetic theory of gases as **kinetic theory of gases**.

The entries for most Western persons are arranged so that one can read a name in correct order by beginning after the first comma, proceeding to the end of the boldface type, returning to the beginning word or words, and proceeding forward to the first comma. Thus, the entry **March, Patrick Dunbar, 2nd Earl of**, is read "Patrick Dunbar, 2nd Earl of March"; the entry **Orléans, Louis, duc d'**, is read "Louis, duc d'Orléans." Names of Far Eastern origin are given in Oriental order, with the surname preceding the personal name (e.g., **Tōjō Hideki, Deng Xiaoping, Nguyen Cao Ky**).

Cross-references

Some cross-reference entries appear in the MICROPAEDIA for the purpose of leading a reader from names that are familiar to alternate names that may not be. Cross-references also appear frequently within or at the ends of standard entries, where they are identified by *see, see also, see under, q.v. (quod vide, "which see"), or qq.v. (quae vide, "which see," plural)*.

Certain entries serve both as relatively brief essays on general subjects and as cross-references to the same subjects treated at greater length and in greater depth in the MACROPAEDIA. Such an entry (e.g., **igneous rock**) begins with a definition of the subject and then provides the following cross-reference: "A brief treatment of igneous rocks follows. For full treatment, *see* MACROPAEDIA: Minerals and Rocks.

Entries on certain broad subjects (e.g., **music**) direct the reader to several relevant articles in the MACROPAEDIA and also to the PROPAEDIA for listings of related articles in the MICROPAEDIA.

Abbreviations

Abbreviations used in the MICROPAEDIA are given in a list that appears at the end of every MICROPAEDIA volume.

Territorial boundaries

In articles and maps indicating disputed geopolitical boundaries and territories, the attribution of sovereignty or administrative subordination to any specific area does not imply recognition of the status claimed by an administering power.

delusion, in psychology, absolute conviction, often preoccupying, that is characterized as idiosyncratic, of personal significance to the deluded individual, and persistent despite logical absurdity or contradictory evidence. Delusions are symptomatic of such mental disorders as paranoia, schizophrenia, and major depression and of such physiological conditions as senile psychosis and delirium. They vary in intensity, extent, and coherence and may represent pathological exaggeration of normal tendencies to rationalization, wishful thinking, and the like. Among the most common are delusions of persecution and grandeur (see paranoia); others include delusions of disease (hypochondriasis, *q.v.*), guilt, erotic delusions (e.g., that one is loved by some famous person), and delusions of control.

Delvaux, Paul (b. Sept. 23, 1897, Antheit, Liège, Belg.—d. July 20, 1994, Veurne), Belgian Surrealist painter, whose canvases portray transfixed humans in a mysterious time and place.

Delvaux
Publi-Press

Delvaux studied first architecture, then painting at the Academie des Beaux-Arts in Brussels. His early work, in the 1920s, was influenced by Postimpressionism and Expressionism. Impressed by the Spaniard Salvador Dalí, the Italian Giorgio de Chirico, and later his fellow Belgian René Magritte, he joined their Surrealist ranks in the mid-1930s. When touring Italy before World War II, he was influenced by its classic architecture (as de Chirico had been) and by the early-16th-century Mannerist paintings, which took liberties with form and space.

A representative Delvaux painting is "The Echo" (1943), in which three somnambulist nudes walk in tandem past dead temples, as if walking through time. In "Entombment" (1951), skeletons bury fellow skeletons. Major exhibitions of his work have been held in North and South America and Africa as well as at many places in Europe; important awards have come to him from Italy and Belgium. From 1950 to 1962 he was a professor of painting in Brussels.

Delvigne, Henri-Gustave (b. 1799, Hamburg [Germany]—d. Oct. 18, 1876, Toulon, France), French army officer and inventor who designed innovative rifles and helped introduce the cylindrical bullet.

Delvigne joined the French army as a youth and attained the rank of captain of the royal guard. In 1826 he introduced the Delvigne rifle, the powder chamber of which was narrower than the barrel. When the rifle ball was dropped down the barrel against the chamber, a few blows of the ramrod expanded the ball

to fit the rifled grooves snugly. Although this system had several drawbacks, it performed well in Algeria and was used extensively.

Delvigne began experimenting with elongated bullets as early as 1830. He designed a cylindro-conical bullet with a hollow base that would expand to fit the rifling grooves when fired. Although he did little to further develop the bullet, the basic idea was adopted by the French inventor Claude-Étienne Minié in the widely used Minié ball.

Delvigne designed a chambered breech rifle that was adopted by France in 1842. His experiments and developments were essential to later advances in firearms. He also introduced new grenade designs.

Delyn, district, Clwyd county, northeastern Wales. It was created in 1974 and covers an area of 107 square miles (278 square km) on the north coast of Wales. The district extends westward from the west bank of the Dee estuary into the Clwydian Hills and borders the districts of Rhuddlan and Glyndwr to the west

and Alyn and Decide to the south and south-east. Across the Dee estuary to the east lie the English districts of Wirral and Ellesmere Port. An obelisk erected by Nehemiah Griffith in 1736 to commemorate the spot where the Saxons and Picts were defeated in AD 430 is located just west of the town of Mold in southern Delyn. Richard II formally surrendered to Henry Bolingbroke at Flint Castle in 1399, after having been persuaded to leave the safety of Conwy Castle by the treacherous earl of Northumberland. (Bolingbroke was crowned Henry IV in the same year.)

The Greenfield Valley at Holywell was one of the birthplaces of the Industrial Revolution, and Delyn remains a heavily industrialized region, although emphasis has shifted from the traditional ironworks and docks to the smaller scale and more diverse industries in engineering, chemicals, and synthetic textiles. Mold, the administrative seat of both Delyn district and Clwyd county, is also the market centre for the limited agricultural crops grown in southern Delyn and in western Alyn and Deeside districts. Flint is an important centre for the rayon industry and the production of chemicals. Tourist attractions in the district include St. Winefride's Well at the parish church in Holywell and the extensive bird havens that have been developed along parts of the shore of the Dee estuary. Daniel Owen, considered by many to be the father of the Welsh novel, was born in Mold in 1836. A railroad, paralleled by a highway farther inland, extends along the banks of the Dee estuary. Pop. (1989 est.) 66,000.

dema deity, any of several mythical ancestral beings of the Marind-Anim of southern New Guinea, the centre of a body of mythology called the *dema* deity complex. The decisive act in *dema* myths is the slaying of a *dema* (ancestral) deity by the ancestral tribe. This act brings about the transition from the ancestral world to the human one. In many ancient myths, the creation of man occurs after the creation of the cosmos. Humans and those attributes that are most decisively human—sexuality, the cultivation of food, and death—are viewed as a decisive break with the previous mode of existence, which was characterized by asexual reproduction, the spontaneous production of food, and immortality.

The rupture between the divine world and the ensuing human world may be brought about by theft of a divine property (e.g., the stealing of fire or grain by a culture hero), which, if viewed as an evil act, regards the human condition as punishment (the Fall complex). In other traditions, man is defined as a clever thief, and the human condition and culture is perceived as the seizing of an opportunity (the Prometheus or trickster complex). Another view is that the rupture between the divine-ancestral and the human worlds is associated with the slaying of an ancestor or an ancestral deity by the ancestors. The term for this structure is the *dema* deity complex.

The most widely quoted example of the *dema* deity complex is the version of the Ceramese myth of Hainuwele, by the Danish anthropologist Adolf E. Jensen. According to this myth, a *dema* man named Amenta found a coconut speared on a boar's tusk and in a dream was instructed to plant it. In six days a palm had sprung from the nut and flowered. Amenta cut his finger, and his blood dripped on the blossom. Nine days later a girl grew asexually from the blossom, and in three more days she became sexually mature. Amenta named her Hainuwele, which means Coconut Branch. During a major religious festival Hainuwele stood in the midst of the dance grounds and excreted valuable objects. After nine days of this activity, the *dema* men dug a hole in the middle of the dance ground, threw Hainuwele in, and danced the ground firm on top of her. Amenta dug up her corpse, dismembered it, and planted the pieces. These pieces gave birth to plant species previously unknown, especially tubers, which have since been the Ceramese's chief food. Another *dema* goddess forced the *dema* men to go through a labyrinth. Some became ordinary mortals; others changed into animals and spirits.

Since its initial discovery in New Guinea, the *dema* complex has been found to be characteristic of the culture of many other tuber cultivators. The basic motif of death and dismemberment appears to reflect the fact that a tuber must be cut up and the pieces buried in order to propagate the species.

Demades (b. c. 380 BC—d. 319), Athenian orator and diplomat who rose from humble origins to a leading place in politics through his vigorous speeches and shrewd ability to fathom popular opinion. Demades opposed Demosthenes' attempt to arouse the Athenians against Philip II of Macedonia, but he fought against the Macedonians at the Battle of Chaeronea (338) and was taken prisoner. On his release he helped negotiate peace between Macedonia and Athens. The admiration of Philip's successor, Alexander the Great, for Demades caused the conqueror to treat Athens leniently after its rebellion in 335. In 324 Demades proposed divine honours for Alexander, but during the winter of 324–323 he was found guilty of accepting bribes against Alexander from Harpalus, Alexander's treasurer. He was heavily fined and lost his citi-

zanship but was reinstated in 322 so that he could negotiate a peace with Antipater (regent in Macedonia) concluding the Lamian War (Athens versus Macedonia, 323–322). Before setting out he persuaded the citizens to pass the death sentence upon Demosthenes and his followers. His embassy resulted in a peace disadvantageous to the Athenians. In 319 he was again sent to the Macedonian court, but either Antipater or his son Cassander, learning that Demades had intrigued with the regent Perdiccas, put him to death. None of Demades' speeches survive.

demand (economics): *see* supply and demand.

demand curve, in economics, a graphic representation of the relationship between product price and the quantity of the product demanded. It is drawn with price on the vertical axis of the graph and quantity demanded on the horizontal axis. With few exceptions, the demand curve is delineated as sloping downward from left to right because price and quantity demanded are inversely related (*i.e.*, the lower the price of a product, the higher the demand or number of sales). This relationship is contingent on certain *ceteris paribus* (other things equal) conditions remaining constant. Such conditions include the number of consumers in the market, consumer tastes or preferences, prices of substitute goods, consumer price expectations, and personal income. A change in one or more of these conditions causes a change in demand, which is reflected by a shift in the location of the demand curve. A shift to the left indicates a decrease in demand, while a movement to the right an increase. *Compare* supply curve.

Demaratus (fl. late 6th–early 5th century BC), king of Sparta, together with Cleomenes

Demaratus, bronze bust; in the Museo Archeologico Nazionale, Naples

Broggi—Art Resource/EB Inc

I, who frustrated Cleomenes' designs on both Athens and Aegina. He was consequently dethroned by Cleomenes on a false charge of illegitimacy, upon which he fled to Persia and was given some small cities in northwestern Asia Minor, which his descendants held in Xenophon's time. The historian Herodotus told several stories of Demaratus' advice and warnings to Xerxes, whom he accompanied on his expedition to Greece in 480.

Demavend, Mount, Persian QOLLEH-YE DAMĀVAND, extinct volcanic peak of the Elburz Mountains, Iran, about 42 miles (68 km) northeast of Tchrān. Estimates of its height vary from about 18,400 feet (5,600 m) to more than 19,000 feet (5,800 m), and it dominates the surrounding ranges by 3,000 to 8,000 feet (900 to 2,450 m). Its steep, snowcapped cone is formed of lava flows and ash and is crowned

Mount Demavend, Iran
Marilyn Silverstone—Magnum

by a small crater with sulfuric deposits. Below the crater are two small glaciers; there are also fumaroles (holes for escaping fumes and gases), hot springs, and mineral deposits of travertine. Mount Demavend is mentioned in several Persian legends, one of which gives it as the resting place of Noah's ark.

deme, Greek DĒMOS, in ancient Greece, country district or village, as distinct from a polis, or city-state. *Dēmos* also meant the common people (like the Latin *plebs*). In Cleisthenes' democratic reform at Athens (508/507 BC), the demes of Attica (the area around Athens) were given status in local and state administration. Males 18 years of age were registered in their local demes, thereby acquiring civic status and rights.

The demes of Attica were local corporations with police powers and their own property, cults, and officials. Members met to decide deme matters and kept property records for purposes of taxation. The *bouletai* (members of the Athenian Boule, or Council of 500) were selected from each deme in proportion to its size. Because the demes were natural districts in origin, their size varied considerably. There were about 150 demes in the 5th century BC and more than 170 later. A typical deme had three *bouletai*, but the largest had as many as 22.

The term deme continued to designate local subdivisions in Hellenistic and Roman times and was applied to circus factions at Constantinople in the 5th and 6th centuries AD.

dementia, chronic, usually progressive deterioration of intellectual functions, usually owing to pathological changes in the brain. Dementia is most commonly seen in the elderly and usually begins with the loss of short-term memory; other initial manifestations can include confusion, irritability, and personality disturbance. Dementia was formerly distinguished from senility, which was considered to affect those over age 65; the term "pre-senile dementia," or Alzheimer's disease, was reserved for younger patients. However, it is now recognized that the same symptoms occur in all victims of dementia regardless of age.

The largest number of those with dementia have the irreversible, degenerative brain disease known as Alzheimer's disease (*q.v.*). These individuals first lose recent memory and higher intellectual functions such as judgment and abstract reasoning, then develop more severe memory losses leading to spatial and temporal disorientation. They may become emotionally unstable and deteriorate physically as well as mentally, ultimately losing even the ability to speak coherently. Dementia is also present in another degenerative brain disease, Pick's disease (*q.v.*).

The most significant other cause of dementia is cerebral arteriosclerosis, which accounts for 20 percent of all cases. Dementia is often a feature in cases of Huntington's chorea, and the syndrome is prominent in cases of paresis (*q.v.*) and some types of encephalitis. Treatable dementias occur in hypothyroidism, other metabolic diseases, and some malignant tumours. Treatment of the underlying disease

in these cases may arrest the progress of dementia but usually does not reverse it. About 10–20 percent of all cases of dementia result from such treatable diseases.

dementia paralytica (disease): *see* paresis.

Demerara River, river in eastern Guyana that rises in the forests of central Guyana and flows northward without important tributaries for 215 miles (346 km) to the Atlantic Ocean at Georgetown. Its narrow estuary and rapid flow keep clear a direct channel of 16–20 feet (5–6 m) to the ocean. Oceangoing steamers ascend 65 miles (105 km) to Linden for bauxite; smaller ships reach Malali, 25 miles (40 km) farther upstream; beyond lie numerous rapids. Its name is that of the old Dutch colony of Demerara, which joined with Essequibo and Berbice in 1831 to become British Guiana (from 1966 the independent republic of Guyana).

demesne, in English feudal law, that portion of a manor not granted to freehold tenants but either retained by the lord for his own use and occupation or occupied by his villeins or leasehold tenants. When villein tenure developed into the more secure copyhold and leaseholders became protected against premature eviction, the "lord's demesne" came to be restricted and usually denoted the lord's house and the park and surrounding lands.

Demesne of the crown, or royal demesne, was that part of the crown lands not granted to feudal tenants but managed by crown stewards until it was later surrendered to Parliament in return for an annual sum. Ancient demesne was land vested in the crown in 1066, the tenants of such land having a number of privileges, such as freedom from tolls. *See also* copyhold; freehold.

Demeter, in Greek religion, daughter of the deities Cronus and Rhea, sister and consort of Zeus (the king of the gods), and goddess of agriculture. Her name means either "grain mother" or "mother earth."

Demeter is rarely mentioned by Homer, nor is she included among the Olympian gods, but the roots of her legend are probably ancient. The legend centred on the story of her daughter Persephone (*q.v.*), who was carried off by Hades, the god of the underworld. Demeter went in search of Persephone and, during her journey, revealed her secret rites to the people of Eleusis, who had hospitably received her (*see* Eleusinian Mysteries). Her distress at her daughter's disappearance was said to have diverted her attention from the harvest and

Demeter of Cnidus, sculpture, mid-4th century BC; in the British Museum

By courtesy of the trustees of the British Museum

caused a famine. In addition to Zeus, Demeter had a consort, Iasion (a Cretan), to whom she bore Plutus (Wealth; *i.e.*, abundant produce of the soil).

Demeter appeared most commonly as a grain goddess. The name *Ioulo* (from *ioulos*, "grain sheaf") has been regarded as identifying her with the sheaf and as proving that the cult of Demeter originated in the worship of the grain mother. The influence of Demeter, however, was not limited to grain but extended to vegetation generally and to all the fruits of the earth, except the bean (the latter being the province of the hero Cyamites). In that wider sense Demeter was akin to Gaea (Earth), with whom she had several epithets in common, and was sometimes identified with the Great Mother of the Gods (Rhea, or Cybele).

Another important aspect of Demeter was that of a divinity of the underworld; she was worshiped as such at Sparta, and especially at the festival of Chthonia at Hermione in Argolis, where a cow was sacrificed by four old women. The epithets Erinyes ("Avenger") and Melaina ("the Black One") as applied to Demeter were localized in Arcadia and stress the darker side of her character.

Demeter also appeared as a goddess of health, birth, and marriage. A certain number of political and ethnic titles were assigned to her, the most important being Amphiktyonis, as patron goddess of the Amphictyonic League, subsequently well known in connection with the temple at Delphi.

Among the agrarian festivals held in honour of Demeter were the following: (1) Haloo, apparently derived from *halōs* ("threshing floor"), begun at Athens and finished at Eleusis, where there was a threshing floor of Triptolemus, her first priest and inventor of agriculture; it was held in the month Poseideon (December). (2) Chloia, the festival of the grain beginning to sprout, held at Eleusis in the early spring (Anthesterion) in honour of Demeter Chloë ("the Green"), the goddess of growing vegetation. This festival is to be distinguished from the later sacrifice of a ram to the same goddess on the sixth of the month Thargelion, probably intended as an act of propitiation. (3) Proerosia, at which prayers were offered for an abundant harvest, before the land was plowed for sowing. It was also called Proarktouria, an indication that it was held before the rising of Arcturus. The festival took place, probably sometime in September, at Eleusis. (4) Thalsia, a thanksgiving festival held in autumn after the harvest in the island of Cos. (5) The Thesmophoria, a women's festival meant to improve the fruitfulness of the seed grain. (6) The Skirophoria held in midsummer, a companion festival.

The attributes of Demeter were connected chiefly with her character as goddess of agriculture and vegetation—ears of grain, the mystic basket filled with flowers, grain, and fruit of all kinds. The pig was her favourite animal, and as a chthonian (underworld) deity she was accompanied by a snake. In Greek art Demeter resembled Hera, but she was more matronly and of milder expression; her form was broader and fuller. She was sometimes riding in a chariot drawn by horses or dragons, sometimes walking, or sometimes seated upon a throne, alone or with her daughter. The Romans identified Demeter with Ceres (*q.v.*).

Demetrius OF ALOPEKA, Demetrius also spelled DEMETRIUS, (fl. late 5th–mid-4th century BC), Greek sculptor, said by ancient critics to have been notable for the lifelike realism of his statues. His style was contrasted with that of Cresilas, an idealizing sculptor of the generation before. Demetrius mainly produced portrait statues, and his portrait of Pellichus, a Corinthian general, was admired by Lucian. A few extant works have been attributed to Demetrius—most notably the head of Lysi-

mache (a priestess of Athena), now in the British Museum—but none has been authenticated. A statue base, found at the Acropolis at Athens, however, bears the inscription that he was the sculptor of such a statue.

Demetrius I (Orthodox patriarch): *see* Dimitrios I.

Demetrius, name of rulers grouped below by country or patriarchate and indicated by the symbol ●.

Foreign-language equivalents:

Greek Dimitrios
Russian Dmitry, or Dmitrii

BACTRIA

● **Demetrius** (fl. 2nd century BC), king of Bactria who was the son and successor of Euthydemus. The historical evidence for Demetrius' reign is slight and open to varying interpretations. According to some scholars, he ruled from about 190 to about 167, when he was killed by Eucratides, who then became king. Earlier, Demetrius had made such extensive conquests in northern India that for a brief time he virtually reestablished there the great Mauryan Empire that had collapsed about 184. Other scholars, however, contend that it was a younger Demetrius (likewise a Bactrian king but not directly related to the son of Euthydemus) who made conquests in India, of a less extensive kind, and lost his kingdom

Demetrius, coin, 2nd century BC

By courtesy of the trustees of the British Museum, photograph, J.R. Freeman & Co. Ltd.

to Eucratides after reigning from about 180 to 165. The fact that one of these two men was the first to strike coins with a bilingual inscription in Greek and Prakrit suggests that he pursued a policy of treating the Indian peoples and the Bactrian Greeks as equals.

MACEDONIA

● **Demetrius I POLIORCETES** (b. 336 BC, Macedonia—d. 283, Cilicia [now in Turkey]), king of Macedonia from 294 to 288 BC.

Demetrius was the son of Alexander the Great's general Antigonos I Monophthalmus, in whose campaigns he commanded with distinction and whose empire, based in Asia, he attempted to rebuild. Unsuccessful against Ptolemy I Soter, satrap of Egypt, and against the Nabataeans, he liberated Athens from the Macedonian Cassander in 307 BC and in 306 decisively defeated Ptolemy at Salamis (Cyprus). From his unsuccessful siege of Rhodes (305) he won the title Poliorcetes ("the Besieger"). Recalled by his father from Greece, he fought in the Battle of Ipsus, in which his father was killed and lost much of his empire (301). Demetrius kept a foothold in Greece and in 294 reoccupied Athens and established himself as king of Macedonia, but in 288 he was driven out by his rivals Lysimachus and Pyrrhus. He finally surrendered to Seleucus I Nicator in Cilicia (285) and died there (283). He is the subject of one of Plutarch's *Lives*.

● **Demetrius II** (b. c. 276 BC—d. 229), king of Macedonia from 239 to 229 BC.

Demetrius gained distinction as a boy by defeating and dethroning Alexander of Epirus, thus saving Macedonia (c. 263). On his acces-

sion he was faced by an Aetolian and Achaean coalition, later joined by an Epirote League. Thus threatened, he was drawn northward by a Dardanian invasion, and after a defeat there he died. His failure seriously weakened both kingdom and monarchy.

PATRIARCHATE

● **Demetrius I**: *see* Dimitrios I.

SYRIA

● **Demetrius I SOTER** (Greek: "Saviour") (b. c. 187 BC—d. 150), king of Syria from 162 to 150 BC. He was one of the line of rulers of the Seleucid dynasty, founded in 312 by a Macedonian successor of Alexander the Great.

Demetrius I, coin, 2nd century BC; in the British Museum

The son of King Seleucus IV Philopator (reigned 187 to 175), Demetrius was sent to Rome as a hostage during his father's reign. While he was away, Syria came under the rule of his uncle, Antiochus IV Euphianes (d. 164), and then of his cousin, Antiochus V. Aided by the Greek statesman and historian Polybius, Demetrius escaped from Rome in 162 and returned to Syria to claim the throne. He defeated the rebel general Timarchus and was recognized as king by the Roman Senate. In 160 he crushed a Jewish rebellion in Palestine. Demetrius died while fighting the pretender Alexander Balas, who was supported by Rome, Egypt, and Pergamum.

● **Demetrius II NICATOR** (Greek: "Victor") (b. 161 BC—d. 125), king of Syria from 145 to 139 and from 129 to 125 BC.

The son of King Demetrius I Soter, he went into exile when his father was killed fighting the usurper Alexander Balas in 150. Demetrius

Demetrius II, coin, 2nd century BC; in the British Museum

returned to Syria (147) with an army of Cretan mercenaries, deposed Balas in 145, and installed himself on the throne. In 140 he drove back a Parthian invasion but was defeated and captured by the Parthians in 139. Demetrius was released from captivity in 129 and returned to Syria, but, during his second

reign, he controlled only part of the kingdom. He was assassinated about four years later.

VLADIMIR

• **Demetrius (II) Donskoy:** *see* Dmitry (II) Donskoy.

Demetrius CHALCONDYLES (b. 1424, Athens [Greece]—d. 1511, Milan [Italy]), Renaissance teacher of Greek and of Platonic philosophy.

In 1447 Demetrius went to Italy, where Cardinal Bessarion became his patron. He was made professor at Padua in 1463. In 1479 he was summoned by Lorenzo de' Medici to Florence, but in 1492 he moved to Milan. He was associated with Marsilio Ficino, Politian, and Teodoro Gaza in the revival of letters in the Western world. One of his pupils at Florence was the German scholar Johann Reuchlin. Demetrius Chalcondyles published the first printed editions of Homer (1488), of Isocrates (1493), and of the *Suda* lexicon (1499), and a Greek grammar (*Erotemata*) in question-and-answer form.

Demetrius OF PHALERON, also called DEMETRIUS PHALEREUS (b. c. 350 BC, Phaleron, near Athens [Greece]—d. c. 280, Egypt), Athenian orator, statesman, and philosopher who was appointed governor of Athens by the Macedonian general Cassander (317 BC). He favoured the upper classes and gave effect to the ideas of such earlier political theorists as Aristotle. When the old democracy was restored in 307, Demetrius escaped to Thebes and later to Egypt, where he became prominent at the court of Ptolemy I, enjoying a high reputation as an orator.

Demetrius, PSEUDO-: *see* Dmitry, False.

Demetrius Cydones: *see* Cydones, Demetrius.

Demetrius Triclinius: *see* Triclinius, Demetrius.

Demetz, Frédéric-Auguste (b. May 12, 1796, Paris, France—d. Nov. 2, 1873, Paris), French jurist and early advocate of the cottage reformatory for juvenile offenders, which anticipated the English system of Borstal reformatories established in the 20th century.

During his time as a judge (1821–40), Demetz was concerned with the problem of sentencing juveniles to live among hardened criminals. He therefore founded in 1840 the farm colony of Mettray in the Loire valley, near Tours. Small groups of juvenile delinquents were assigned to separate cottages, which were equipped with workshops and were supervised by a family head and two assistants. Outdoor work and recreation, as well as religious and primary education, were provided. The arrangement at Mettray resembled that of the later Borstal institutions in England. Demetz wrote several books in which he set forth his theories on penology.

Demidov FAMILY, Russian family that acquired great wealth in the 18th century, largely through iron production and mining, and became patrons of the arts and sciences.

Nikita Demidovich Antufyev (1656–1725) was a blacksmith from the western Russian city of Tula, who took the surname Demidov in 1702. He began to accumulate his family's fortune by manufacturing weapons and, after receiving land grants from Peter I the Great (reigned 1682–1725), by building and operating an iron foundry at Tula. Peter made Demidov, a former serf, a nobleman.

Akinfy Demidov (1678–1745), Nikita's son, increased his inherited wealth by expanding his holdings and establishing gold, silver, and copper mines, mainly in the Ural Mountains. Largely as a result of Nikita's and Akinfy's

efforts, the Demidov family, by the end of the 18th century, controlled vast estates and enterprises and produced about 40 percent of the country's output of cast iron.

Subsequently, other members of the family engaged in philanthropic activities. Akinfy's nephew Pavel Grigoryevich Demidov (1738–1821) traveled extensively and became a benefactor of Russian education. His nephew Count Nikolay Nikitich Demidov (1773–1828) directed the family's mining business and also contributed liberally to scientific education, mainly in Moscow. Nikolay's elder son, Pavel Nikolayevich Demidov (1798–1840), founded an annual prize for Russian literature, to be awarded by the Academy of Sciences. Nikolay's younger son, Anatoly Nikolayevich Demidov (1812–70), also a traveler and patron of the arts, lived for many years in Italy, purchased the Tuscan title prince of San Donato, and married (1840) Princess Mathilde, Jérôme Bonaparte's daughter and Napoleon I's niece.

deMille, Agnes: *see* de Mille, Agnes.

DeMille, Cecil B., in full CECIL BLOUNT DEMILLE (b. Aug. 12, 1881, Ashfield, Mass., U.S.—d. Jan. 21, 1959, Hollywood, Los Angeles, Calif.), American motion-picture producer-director whose use of spectacle attracted vast audiences and made him a dominant figure in Hollywood for almost five decades.

Cecil B. DeMille
EB Inc

He was the son of the playwright Henry Churchill DeMille. After studying at the Pennsylvania Military College and the American Academy of Dramatic Arts, he began his career in the theatre as an actor in 1900. He was soon collaborating with his brother, the playwright William Churchill DeMille.

In 1913 DeMille joined Jesse Lasky, Samuel Goldwyn, and Arthur Freed in forming the Jesse Lasky Feature Play Company, which subsequently became Paramount Pictures. DeMille's own first film was a western, *The Squaw Man* (released 1914), one of the first full-length feature films produced in Hollywood. His ability to give the public what it wanted soon made him a "name" director in the days when directors were virtually unknown. From 1919 to 1923 DeMille made comedies that reflected the postwar freedom from moral restraint, but then he began to produce films dealing with biblical subjects and featuring spectacular crowd scenes and sets. Among these were *The Ten Commandments* (1923) and *The King of Kings* (1927), which, it is estimated, was seen by 800,000,000 people.

DeMille was known for his strong and asserive personality: he was the first director to use a megaphone on the set and the first to install a loudspeaker system for issuing orders. He was also noted for his right-wing political views and his strenuous opposition to labour unions. In later decades DeMille concentrated on large productions, culminating in *Samson and Delilah* (1949), *The Greatest Show on Earth* (which won the Academy Award for the best picture of 1952), and a second version of *The Ten Commandments* (1956), his 70th and last film. His other major films included *The Sign of the Cross* (1932) and *Union Pacific*

(1939). From 1936 to 1945 DeMille appeared on radio in a popular weekly series of adaptations of recent motion pictures.

Although many critics dismissed DeMille's films as devoid of artistic merit, he was conspicuously successful in a genre—the epic—that he made distinctively his own.

Deming, city, seat (1901) of Luna county, southwestern New Mexico, U.S., about 55 miles (89 km) west of Las Cruces. The city is located in the broad valley of the Mimbres River (there flowing underground) and is surrounded by mountains. Deming was founded in 1881 as a railroad service point at the junction of the Santa Fe and Southern Pacific railways. It was named for Mary Ann Deming Crocker, wife of Charles Crocker, one of the principal builders of the Southern Pacific Railroad. Located on U.S. Interstate Highway 10, it developed as the trade and shipping centre for an irrigated farm and ranch area producing cotton, livestock, feed grain, and fruit. Mining and smelting of copper, manganese, lead, fluorspar, and silver also are important to the economy. The city has become a popular retirement community. Inc. 1902. Pop. (2002 est.) 14,126.

Deming, W. Edwards, in full WILLIAM EDWARDS DEMING (b. Oct. 14, 1900, Sioux City, Iowa, U.S.—d. Dec. 20, 1993, Washington, D.C.), American statistician, educator, and consultant whose advocacy of quality-control methods in industrial production aided Japan's economic recovery after World War II and its subsequent rise to global supremacy in many industries in the late 20th century.

The son of a small-town lawyer, Deming attended the University of Wyoming (B.S., 1921), University of Colorado (M.S., 1924), and Yale University (Ph.D. in mathematical physics, 1928). He then taught physics at several universities, worked as a mathematical physicist at the United States Department of Agriculture (1927–39), and was a statistical adviser for the U.S. Census Bureau (1939–45). From 1946 to 1993 he was a professor of statistics at New York University's graduate school of business administration, and he taught at Columbia University. He also was a research consultant for private business.

Deming became interested in the use of statistical analysis to achieve better quality control in industry in the 1930s, and in 1950 he was invited to Japan by Japanese business leaders to teach that nation's executives and engineers about the new methods. Deming's ideas were eagerly adopted by Japanese companies, whose commitment to quality control helped Japanese products to eventually dominate the market in many parts of the world. Japan's Deming Prize (established 1951), which is given annually to major corporations who win a rigorous quality-control competition, is named for Deming.

In the 1980s Deming's ideas were taken up by American corporations as they sought to compete more effectively against foreign manufacturers. Deming's quality-control methods centred on systematically tallying product defects, analyzing their causes, correcting the latter, and then recording the effects of the corrections on subsequent product quality.

Demirel, Süleyman (b. Oct. 6, 1924, İslâmköy, Turkey), politician and civil engineer who served seven times as prime minister of Turkey and was president from 1993 to 2000.

Born into a peasant family, Demirel graduated in 1948 from the Technical University of Istanbul as an engineer. He entered politics in 1961 and was elected to the National Assembly that same year as a member of the Justice Party (JP), becoming the party's leader in 1964. On Oct. 27, 1965, after the general elections, he became the youngest prime minister in his country's history. As prime minister he improved Turkey's ties with its NATO allies

and instituted development programs for his basic constituency, the Turkish peasantry.

Demirel was reelected in 1969, but his moderate policies faced growing opposition from both the left and the right, and, upon his refusal to allow the military to assume a policy-making role in efforts to combat terrorism, Turkey's military commanders forced him to resign in March 1971. In March 1975 a coalition of the JP and smaller right-wing parties in a Nationalist Front once more restored Demirel to the prime ministry.

Demirel pursued a policy of economic growth, in spite of civil violence and terrorism from extremist factions, inflation, and a trade deficit. But the electoral coalitions that now enabled him to maintain power were inherently weak, unstable, and governmentally ineffective. His fourth ministry fell in June 1977, but he achieved a fifth prime ministry from July to December 1977 and a sixth from November 1979 to September 1980. As the country continued to be torn apart by extremist violence, the military overthrew his government on Sept. 12, 1980. Demirel was banned from participating in politics for a time, but he once more was returned to office as prime minister in November 1991. He resigned that post in May 1993 after he was elected president of Turkey. He left office in 2000.

Demiurge, Greek ΔΕΜΙΟΥΡΓΟΣ ("public worker"), plural ΔΕΜΙΟΥΡΓΟΙ, in philosophy, a subordinate god who fashions and arranges the physical world to make it conform to a rational and eternal ideal. Plato adapted the term, which in ancient Greece had originally been the ordinary word for "craftsman," or "artisan" (broadly interpreted to include not only manual workers but also heralds, soothsayers, and physicians), and which in the 5th century BC had come to designate certain magistrates or elected officials.

Plato used the term in the dialog *Timaeus*, an exposition of cosmology in which the Demiurge is the agent who takes the preexisting materials of chaos, arranges them according to the models of eternal forms, and produces all the physical things of the world, including human bodies. The Demiurge is sometimes thought of as the Platonic personification of active reason. The term was later adopted by some of the Gnostics, who, in their dualistic worldview, saw the Demiurge as one of the forces of evil, who was responsible for the creation of the despised material world and was wholly alien to the supreme God of goodness.

democracy, literally, rule by the people (from the Greek *dēmos*, "people," and *kratos*, "rule"). A brief treatment of democracy follows. For full treatment, see MACROPAEDIA: Democracy.

The term has three basic senses in contemporary usage: (1) a form of government in which the right to make political decisions is exercised directly by the whole body of citizens, acting under procedures of majority rule, usually known as direct democracy; (2) a form of government in which the citizens exercise the same right not in person but through representatives chosen by and responsible to them, known as representative democracy; and (3) a form of government, usually a representative democracy, in which the powers of the majority are exercised within a framework of constitutional restraints designed to guarantee all citizens the enjoyment of certain individual or collective rights, such as freedom of speech and religion, known as liberal, or constitutional, democracy.

Democracy had its beginnings in certain of the city-states of ancient Greece in which the whole citizen body formed the legislature. Citizens were eligible for a variety of executive and judicial offices, some of which were filled by elections, while others were assigned by lot. There was no separation of powers, and all officials were fully responsible to the popular as-

sembly, which was qualified to act in executive and judicial as well as legislative matters. Greek democracy was a brief historical episode that had little direct influence on the development of modern democratic practices. Two millennia separated the fall of the Greek city-state and the rise of modern constitutional democracy.

Modern concepts of democratic government were shaped to a large extent by ideas and institutions of medieval Europe, notably the concept of divine, natural, and customary law as a restraint on the exercise of power. Highly significant was the growing practice by European rulers of seeking approval of their policies—including the right to levy taxes—by consulting the different "estates," or group interests, in the realm. Gatherings of representatives of these interests were the origin of modern parliaments and legislative assemblies. The first document to notice such concepts and practices is Magna Carta (*q.v.*) of England, granted by King John in 1215.

Also of fundamental importance were the profound intellectual and social developments of the Enlightenment and the American and French revolutions, notably the emergence of concepts of natural rights and political equality. Two seminal documents of this period are the American Declaration of Independence (1776) and the French Declaration of the Rights of Man and of the Citizen (1789; see Independence, Declaration of; Rights of Man and of the Citizen, Declaration of the).

Representative legislative bodies, freely elected under (eventual) universal suffrage, became in the 19th and 20th centuries the central institutions of democratic governments. In many countries, democracy also came to imply competition for office, freedom of speech and the press, and the rule of law.

Numerous authoritarian and totalitarian states, notably the communist nations of the 20th century, adopted outwardly democratic governments that nonetheless were dominated by a single authorized party without opposition.

Democratic Centralist, Russian ДЕМОКРАТИЧЕСКИЙ ЦЕНТРАЛИСТ, in the history of the Soviet Union, member of an opposition group within the Communist Party that objected to the growing centralization of power in party and government organs.

The Democratic Centralists developed in 1919–20 as the central government and party organs tightened their control over local soviets and party units. The group was composed largely of intellectuals, many of whom had opposed the centralization of state control over industry in 1918. The Democratic Centralists continued their protest through 1920; but at the 10th Party Congress (March 1921) opposition groups were condemned, and the Democratic Centralists, satisfied by the passage of resolutions supporting organizational reforms, became temporarily inactive.

They revived their protests, however, as the party failed to implement its resolutions. In 1923 they joined other opposition elements to criticize the central party leadership (Declaration of the Forty-Six, presented to the Politburo on Oct. 15, 1923), and in 1926–27 they sided with the opposition against Joseph Stalin's increasing domination of the party. But Stalin defeated the opposition; at the 15th Party Congress (December 1927), 18 Democratic Centralists were expelled from the party. During the purges of the 1930s most were arrested and either sent to labour camps or executed.

Democratic Constitutional Rally, also called DEMOCRATIC CONSTITUTIONAL ASSEMBLY, formerly (1964–88) DESTOURIAN SOCIALIST PARTY, or (1934–64) NEO-DESTOUR, French RASSEMBLEMENT CONSTITUTIONNEL DÉMOCRATIQUE, PARTI SOCIALISTE DESTOURIEN, or NÉO-DESTOUR, Tunisian political

party that led the movement for independence from France (1956) and ruled Tunisia thereafter.

The Neo-Destour was formed in 1934 by discontented young members of the more conservative Destour (*q.v.*). After a bitter struggle with the parent organization, it became the predominant party under the leadership of Habib Bourguiba in 1937. It was harassed by French authorities throughout the 1940s and began an armed rebellion in 1953 that led to Tunisian independence in 1956.

A Neo-Destour government was then formed. In 1958 Bourguiba was appointed the first premier of Tunisia, and in 1959 he was overwhelmingly voted president. Internally, however, the Neo-Destour had begun to split in the early 1950s, one group supporting Bourguiba, the other aligning itself with Salah Ben Yusuf, who had led the party when Bourguiba was imprisoned by the French. Ben Yusuf was expelled from the party in 1955, established himself in Cairo, and initiated a six-year guerrilla campaign against the Neo-Destour, the French, and Bourguiba. He was found murdered on Aug. 14, 1961, and his followers soon disappeared.

The party meanwhile consolidated its hold on all levels of Tunisian society and constituted itself (1963) as Tunisia's sole political party, renaming itself in 1964. Not until 1981 were opposition parties permitted. In 1987 Zine el-Abidine Ben Ali succeeded Bourguiba as leader of the party and president of Tunisia. Under Ben Ali the party pursued free market economic policies and a more open political atmosphere. To reflect these changes, the party's name was again changed in 1988.

Democratic Party (Japan): see Minseitō.

Democratic Party, in the United States, one of the two major political parties. Historically, the Democratic Party has supported organized labour, ethnic minorities, and progressive reform. It tends to favour greater government intervention in the economy and to oppose government intervention in the private, noneconomic affairs of citizens. The logo of the Democratic Party is the donkey, though it has never been officially adopted by the party.

The Democratic Party is the oldest political party in the United States and among the oldest in the world. It traces its roots to 1792, when followers of Thomas Jefferson adopted the name Republican to emphasize their anti-monarchical views. In 1800 Jefferson was elected president, ushering in a period of prolonged dominance in which the party (which had adopted the label Democratic-Republican in 1798) held the presidency continuously until 1829. The party split during the 1820s, largely between factions supporting either John Quincy Adams or Andrew Jackson, whose supporters became known as Democrats (or as Jacksonian Democrats). Adams defeated Jackson in 1824 (though Jackson won the largest number of popular and electoral votes), but in 1828 Jackson won the presidency.

From 1828 to 1856 the Democrats won all but two presidential elections (1840 and 1848). During the 1840s and '50s, however, the party suffered serious internal strains over the issue of extending slavery to the Western territories. The issue split the Democrats in 1860; Southern Democrats nominated John C. Breckinridge and Northern Democrats nominated Stephen A. Douglas, paving the way for Republican Abraham Lincoln to be elected president with about 40 percent of the vote.

From the 1870s to the 1890s the Democratic and Republican parties were in rough balance at the federal level—except in the South, where the Democrats dominated. From 1861 to 1897, however, the Democratic Party held the presidency only during the two terms of

Grover Cleveland (1885–89 and 1893–97). During Cleveland's second term the country sank into an economic depression. The party at this time was basically conservative and agrarian-oriented, opposing the interests of big business (especially protective tariffs) and favouring cheap-money policies, which were aimed at maintaining low interest rates. In 1896 the Democrats split disastrously over the free-silver and Populist program of their presidential candidate, William Jennings Bryan. Bryan lost by a wide margin to Republican William McKinley, a conservative who supported high tariffs and money based only on gold.

From 1897 to 1933 the Democrats held the presidency only during the two terms of Woodrow Wilson (1913–21). Wilson's presidency was something of an anomaly, as he won in 1912 largely because of a split within the Republican Party. Wilson championed various progressive economic reforms, including the breaking up of business monopolies and broader federal regulation of banking and industry. His brand of idealism and internationalism proved less attractive to voters during the spectacular prosperity of the 1920s than the Republicans' frank embrace of big business. The Democrats lost decisively the presidential elections of 1920, 1924, and 1928.

The presidential election of 1932 took place in the midst of the Great Depression. Led by Franklin D. Roosevelt, the Democrats not only regained the presidency but also replaced the Republicans as the majority party throughout the country. Roosevelt's New Deal policies forged a broad coalition—including small farmers, Northern city dwellers, organized labour, European immigrants, liberals, intellectuals, and reformers—that enabled the Democrats to retain the presidency until 1952 and to control both houses of Congress for most of the period from the 1930s to the mid-1990s. Roosevelt was reelected in 1936, 1940, and 1944—the only president to be elected to more than two terms. Upon his death in 1945 he was succeeded by his vice president, Harry S. Truman, who was narrowly elected in 1948.

Republican Dwight D. Eisenhower won overwhelming victories against Democrat Adlai E. Stevenson in 1952 and 1956. The Democrats won the presidency in 1960, when John F. Kennedy narrowly defeated Eisenhower's vice president, Richard M. Nixon. The Democrats' championing of civil rights and racial desegregation under Truman, Kennedy, and especially Lyndon B. Johnson cost the party the traditional allegiance of many Southern Democrats. Johnson defeated Republican Barry M. Goldwater by a landslide in 1964, but his popularity waned because of bitter opposition to the Vietnam War.

From 1968 to 1988 the Democrats lost five of six presidential elections. In 1972 the party nominated antiwar candidate George S. McGovern, who was defeated by Nixon in one of the biggest landslides in U.S. electoral history. In 1976, two years after Nixon resigned the presidency amid the Watergate scandal, Jimmy Carter, the Democratic governor of Georgia, was narrowly elected president. Although Carter orchestrated the Camp David Accords between Egypt and Israel, his presidency was plagued by a sluggish economy and by the crisis over the kidnapping and prolonged captivity of U.S. diplomats in Iran in 1979–80. Carter was decisively defeated for reelection in 1980, and the Republicans also handily won the presidential elections of 1984 and 1988. Despite its losses in the presidential elections of the 1970s and '80s, the Democratic Party continued to control both houses of Congress for most of the period.

In 1992 Arkansas Governor Bill Clinton recaptured the presidency for the Democrats. Clinton's support of international trade agree-

ments (e.g., the North American Free Trade Agreement) and his willingness to cut spending on social programs to reduce budget deficits alienated the left wing of his party and many traditional supporters in organized labour. In 1994 the Democrats lost control of both houses of Congress. During Clinton's second term the country experienced a period of prosperity not seen since the 1920s, but a scandal involving Clinton's relationship with an intern led to his impeachment in 1998 (he was acquitted in 1999). In 2000 Al Gore, Clinton's vice president, won 500,000 more popular votes than Republican George W. Bush but was narrowly defeated (271–266) in the electoral college.

Democratic Progressive Party (DPP), Taiwanese political party formed in 1986 by a group of independents who initially sought self-determination for the people of Taiwan, democratic freedoms, the establishment of economic ties with China, and a multiparty system. Despite a ban on new political parties (part of the martial law regulations that were in effect from 1949 to 1987), the DPP was informally organized in 1983 and was the first opposition party to be officially recognized by the government of Taiwan (1986). It won 21 of 101 parliamentary seats in 1989. Amid debates over Taiwan's independence, the party's popularity declined in the early 1990s. In the late 1990s, however, support for the party surged, and in 2000 its leader, Chen Shui-bian (*q.v.*), was elected president. In December 2001 the DPP won 87 seats in the now 225-seat Legislative Yuan, replacing the Nationalist Party, which had ruled Taiwan continually from its founding, as the largest party in the legislature. Chen was narrowly reelected president in 2004.

Democratic-Republican Party, in U.S. history, offshoot of the Republican Party (*q.v.*: 1801–25) and the forerunner of the modern Democratic Party.

Democrats of the Left, Italian DEMOCRATICI DI SINISTRA (DS), formerly (1921–91) ITALIAN COMMUNIST PARTY and (1991–98) DEMOCRATIC PARTY OF THE LEFT, Italian political party and historically western Europe's largest communist party.

The party was founded in 1921 as the Italian Communist Party (Partito Comunista Italiano; PCI) by dissidents of the extreme left wing of the Italian Socialist Party. PCI members were elected to parliament before Benito Mussolini's Fascist Party outlawed all political parties in 1926. The PCI then went underground to establish an organization that later proved important to the Italian Resistance.

After World War II the PCI joined five other antifascist parties in coalition governments until May 1947. For the next several decades it was successful at the polls but did not formally enter government. The party adopted a reform-oriented communism that rejected violence and was able to win power at the local level, particularly in central Italy.

In the mid-1950s communist leader Palmiro Togliatti helped dissociate the party from the Soviet Union by proposing the concept of "polycentrism," a form of limited independence among communist parties. In 1968 the party won 27 percent of the vote, but the persistent Cold War blocked serious consideration of the communists' entry into a governing coalition at the national level.

Enrico Berlinguer, who led the party from 1972 until his death in 1984, was one of the leading proponents of Eurocommunism (*q.v.*). In 1973 Berlinguer proposed a "historic compromise" with the Christian Democrats. Berlinguer's compromise, never popular with the party's base, led to PCI support for successive governments between 1976 and 1979, though the party never formally entered a governing coalition.

By the late 1980s, events in eastern Europe made the communist label increasingly distasteful to many in the party. The party changed its name to become the Democratic Party of the Left in 1991 and adopted its present name in 1998. In the 1990s the party joined with other centre-left parties to form the Olive Tree coalition. From 1996 to 2001 the party was part of Italy's governing coalition, and its leader, Massimo D'Alema, served as prime minister from 1998 to 2001.

"De," "la," and similar components of a name when followed by a space, are alphabetized as separate words (e.g., De Forest, Lee). When they are joined to the following part of a name, the combination is treated as a single word (e.g., DeForest, John William).

Democritus (b. c. 460 BC—d. c. 370), Greek philosopher, a central figure in the development of the atomic theory of the universe.

Knowledge of Democritus' life is largely limited to untrustworthy tradition: it seems that he was a wealthy citizen of Abdera, in Thrace; that he traveled widely in the East; and that he lived to a great age. According to Diogenes Laërtius, his works numbered 73; only a few hundred fragments have survived.

Democritus' physical and cosmological doctrines were an elaborated and systematized version of those of his teacher, Leucippus. To account for the world's changing physical phenomena, Democritus asserted that space, or the Void, had an equal right with reality, or Being, to be considered existent. He conceived of the Void as a vacuum, an infinite space in which moved an infinite number of atoms that made up Being (*i.e.*, the physical world). These atoms are eternal and invisible; absolutely small, so small that their size cannot be diminished (hence the name *atomon*, or "indivisible"); absolutely full and incompressible, as they are without pores and entirely fill the space they occupy; and homogeneous, differing only in shape, arrangement, position, and magnitude. But, while atoms thus differ in quantity, differences of quality are only apparent, owing to the impressions caused on our senses by different configurations and combinations of atoms. A thing is hot or cold, sweet or bitter, or hard or soft only by convention; the only things that exist in reality are atoms and the Void. Thus, the atoms of water and iron are the same, but those of water, being smooth and round and therefore unable to hook onto one another, roll over and over, whereas those of iron, being rough, jagged, and uneven, cling together and form a solid body. Because all phenomena are composed of the same eternal atoms, it may be said that nothing comes into being or perishes in the absolute sense of the words, although the compounds made out of the atoms are liable to increase and decrease, explaining a thing's appearance and disappearance, or "birth" and "death."

Just as the atoms are uncaused and eternal, so too, according to Democritus, is motion. Democritus posited the fixed and "necessary" laws of a purely mechanical system, in which there was no room for an intelligent cause working with a view to an end. He explained the origin of the universe as follows. The original motion of the atoms was in all directions—it was a sort of "vibration"; hence there resulted collisions and, in particular, a whirling movement, whereby similar atoms were brought together and united to form larger bodies and worlds. This happened not as the result of any purpose or design but rather merely as the result of "necessity"; *i.e.*, it is the normal manifestation of the nature of the atoms themselves. Atoms and Void being infinite in number and extent, and motion having always existed, there

must always have been an infinite number of worlds, all consisting of similar atoms in various stages of growth and decay.

Democritus devoted considerable attention to perception and knowledge. He asserted, for example, that sensations are changes produced in the soul by atoms emitted from other objects that impinge on it; the atoms of the soul can be affected only by the contact of other atoms. But sensations such as sweet and bitter are not as such inherent in the emitted atoms, for they result from effects caused merely by the size and shape of the atoms; e.g., sweet taste is due to round and not excessively small atoms. Democritus also was the first to attempt to explain colour, which he thought was due to the "position" (which he differentiated from shape) of the constituent atoms of compounds. The sensation of white, for instance, is caused by atoms that are smooth and flat so as to cast no shadow; the sensation of black is caused by rough, uneven atoms.

Democritus attributed popular belief in the gods to a desire to explain extraordinary phenomena (thunder, lightning, earthquakes) by reference to superhuman agency. His ethical system, founded on a practical basis, posited an ultimate good ("cheerfulness") that was "a state in which the soul lives peacefully and tranquilly, undisturbed by fear or superstition or any other feeling."

demography, statistical study of human populations, especially with reference to size and density, distribution, and vital statistics (births, marriages, deaths, etc.). Contemporary demographic concerns include the "population explosion," the interplay between population and economic development, the effects of birth control, urban congestion, illegal immigration, and labour force statistics. For a discussion of the objects of demographic study, see population (in biology and physical anthropology). See also census.

The roots of statistical demography may be found in the work of the Englishman John Graunt; his work *Natural and Political Observations . . . Made upon the Bills of Mortality* (1662) examines the weekly records of deaths and baptisms (the "bills of mortality") dating back to the end of the 16th century. In search of statistical regularities, Graunt made an estimate of the male-female ratios at birth and death-birth ratios in London and rural communities. His most celebrated contribution was his construction of the first mortality table; by analyzing birth and death rates he was able to estimate roughly the number of men currently of military age, the number of women of childbearing age, the total number of families, and even the population of London. Another such study was undertaken by Johann Süssmilch, whose *Die Göttliche Ordnung* (1741; "The Divine Order") analyzed the populations of 1,056 parishes in Brandenburg and various cities and provinces of Prussia. Süssmilch constructed several mortality tables, most notably the first such table for the whole population of Prussia (1765).

In 18th-century Europe, the development of life insurance and growing attention to public health produced an increased awareness of the significance of mortality studies. Civil registries of significant public events (births, deaths, and marriages) began in the 19th century to supplant church registries. Censuses of the population also developed during the 19th century.

For most of the 19th century, demographic studies continued to emphasize the phenomenon of mortality; it was not until demographers noted that a considerable decline of

fertility had taken place in the industrialized countries during the second half of the 19th century, that they began to study fertility and reproduction with as much interest as they studied mortality. The phenomenon of differential fertility, with its implications about selection and more particularly about the evolution of intelligence, evoked widespread interest as shown in Charles Darwin's theories and in the works of Francis Galton. During the period between the two world wars, demography took on a broader, interdisciplinary character. In 1928 the International Union for the Scientific Study of Population was founded.

In spite of increasing sophistication in the analysis of statistics and the proliferation of research institutes, periodicals, and international organizations devoted to the science of demographics, the basis for most demographic research continues to lie in population censuses and the registration of vital statistics. Even the most meticulously gathered census is not completely accurate, however, and birth, death, and marriage statistics—based on certificates drawn up by local authorities—are accurate mostly in countries with a long tradition of registry.

demoiselle (fish): see damselfish.

Demolder, Eugène (b. Dec. 16, 1862, Brussels, Belg.—d. Oct. 8, 1919, Essonnes, Fr.), Belgian novelist and storywriter, writing in French, who was a member of the *Jeune Belgique* ("Young Belgium") literary renaissance of the late 19th century.

He was trained to be a lawyer, and his memoirs, *Sous la robe* (1897; "Under the Robe"), provide a record of the professional and cultural life of a class that was in the forefront of Belgian literary reform. Demolder's novels are noted for their evocation of atmosphere and may be regarded more as a sequence of tableaux than as coherent narratives.

In early works, such as *La Légende d'Yperdamme* (1891), he transposed stories from the Gospels into Flemish medieval settings whose scenes have been compared with the paintings of Bruegel. In *La Route d'éméraude* (1899; "The Emerald Road") Demolder provided rich graphic descriptions in his story of the life of a would-be painter in the Low Countries in the 17th century. Demolder's other important novel, *Le Jardinier de la Pompadour* (1904; "Madame de Pompadour's Gardener"), is set in France; in this evocation of an elegant period, Demolder's style and subject are in perfect harmony. His *L'Espagne en auto* (1906; "Spain by Auto") is one of the earliest narratives of automobile travel.

demon, also spelled DAEMON, in religions worldwide, any of numerous malevolent spiritual beings, powers, or principles that mediate between the transcendent and temporal realms.

A brief treatment of demons follows. For full treatment, see MACROPAEDIA: Doctrines and Dogmas, Religious.

In ancient Greece a demon (Greek *daimon*) was a supernatural power, and the term was employed almost interchangeably by Homer with *theos*, for a god. The distinction was that *theos* emphasized the personality of the god, and demon his activity. Hence, demon was regularly applied to sudden or unexpected supernatural interventions not attributable to any particular deity. It became commonly the power determining a person's fate, and an individual could have a personal demon. As early as Hesiod, the dead of the Golden Age became demons; and later philosophical speculation envisaged these beings as lower than the gods (possibly mortal) but as superior to humanity. The Christians, therefore, attributed the actions of the pagan gods to demons identified as fallen angels.

In Zoroastrianism, a religion founded by

the 6th-century-BC Persian prophet Zoroaster, the hierarchy of demons (*daevas*) is headed by Angra Mainyu (later called Ahriman), the Evil, or Destructive, Spirit. The demons are in constant battle with Ahura Mazda (later called Ormazd), the Good Lord.

The hierarchy of demons in Judaism, which is rooted in ancient Middle Eastern and Zoroastrian demonology after the postexilic period (after 538 BC), is quite varied. The prince of the forces of evil (Hebrew *shedim*, meaning "demons" and applied to foreign gods, or *se'irim*, meaning "hairy demons"), who often were believed to inhabit desert wastes, ruins, and graves and to inflict humanity with various physical, psychological, and spiritual disorders, was called by different names: Satan (the Antagonist), Belial (the spirit of perversion, darkness, and destruction), Mastema (Enmity, or Opposition), and other names. Though the Old Testament refers to Satan as the prosecutor of God's celestial court (Zech. 3; Job 1-2), a hierarchy of demons under Satan or other princes of evil was developed in intertestamental literature and later Judaism.

The hierarchy of demons in Christianity is based on various sources: Jewish, Zoroastrian, Gnostic (a syncretistic religious dualistic-belief system in which matter is viewed as evil, the spirit good, and salvation as being attainable through esoteric knowledge, or gnosis), and the indigenous religions that succumbed to Christian missionizing. In the New Testament, Jesus speaks of Beelzebub as the chief of demons and equates him with Satan. In the European Middle Ages and the Reformation period, various hierarchies of demons were developed, such as that associated with the seven deadly sins: Lucifer (pride), Mammon (avarice), Asmodeus (lechery), Satan (anger), Beelzebub (gluttony), Leviathan (envy), and Belphegor (sloth).

The Islāmic hierarchy of demons is headed by Iblis (the devil), who also is called *Shayṭān* (Satan) or *'aduw Allāh* ("Enemy of God"). Based to a great extent on Jewish and Christian demonology, Iblis became the leader of a host of *jinn*, spiritual beings that generally bode evil.

In Hinduism, the *asuras* (the Zoroastrian *ahuras*) are the demons who oppose the *devas* (the gods). Among the various classes of *asuras* are *nāgas* (serpent demons), *Ahi* (the demon of drought), and *Kāmsa* (an archdemon). Demons that afflict humans include the *rākṣasas* (grotesque beings who haunt cemeteries, impel the performance of foolish acts, and attack *sadhus* (saintly men) and *piśacas* (beings who haunt places where violent deaths have occurred)).

Buddhists often view their demons as forces that inhibit the achievement of Nirvāna (bliss, or the extinction of desire); an important example is Māra, an arch tempter, who, with his daughters, Rati (Desire), Rāga (Pleasure), and Tanhā (Restlessness), attempted to dissuade Siddhārtha Gautama, the Buddha, from achieving his enlightenment. As Mahāyāna (Greater Vehicle) Buddhism spread to Tibet, China, and Japan, many of the demons of the folk religions of these areas (e.g., the Chinese *kuei-shen*; the Japanese *oni*) were incorporated into Buddhist beliefs.

Demonesi Insulae (Turkey): see Kızıl Adalar.

Demophoon, in Greek mythology, the son of Celeus, king of Eleusis. The goddess Demeter, wandering in search of her daughter Persephone, became Demophoon's nurse. As an act of kindness to those who had sheltered her, she attempted to immortalize him by burning out his mortal parts but was surprised in the act by his mother, who thought that she was harming the boy. Incensed, Demeter quickly withdrew the child from the fire, thus leaving

him susceptible to death. In another version the surprise resulted in Demophoon's death in the flames. Shortly thereafter Demeter departed from Eleusis.

Demopolis, city, Marengo county, western Alabama, U.S., at the confluence of the Tombigbee and Black Warrior rivers, which form a navigable waterway. Founded in 1817 by Napoleonic exiles who unsuccessfully tried to raise olives and grapes, it was named Demopolis (Greek: "city of the people") and was chartered in 1819. A cotton-plantation society flourished (1830–60), and many fine Greek Revival mansions were built, including Gaineswood and Bluff Hall. Later, beef cattle, dairying, soy beans, and lumbering replaced dependence on cotton. Manufacturing industries (chiefly lingerie, paperboard and pulp, and chemicals) also developed, with shipping provided by the Demopolis Inland State Docks (1956). Recreational activities focus on nearby Lake Demopolis, with a 400-mi (640-km) shoreline, formed by the dam on the Tombigbee. Pop. (1990) 7,512.

dēmos (in ancient Greece): *see* deme.

Demosthenes (d. 413 BC), Athenian general who proved to be an imaginative strategist during the Peloponnesian War (Athens versus Sparta, 431–404).

In 426 he unsuccessfully besieged the Corinthian colony of Leukas and was severely defeated in an attempted invasion of Aetolia. Demosthenes redeemed these failures by successfully defending Naupactus, the Athenian naval base in the Gulf of Corinth, against a Spartan land attack and by winning two decisive victories over the Spartans, at Olpae near Argos and at Idomene in the hills to the north of Argos. In 425 he was authorized to use the fleet for operations around the Peloponnese. He fortified the promontory of Pylos in Messenia and, while the rest of the flotilla sailed on to Sicily, remained with five ships at the harbour of the peninsula at Pylos. There he managed to resist Spartan attacks. The Spartans occupied the neighbouring peninsula of Sphacteria but were besieged after their ships were driven off by the returning Athenian fleet. The politician Cleon joined Demosthenes in defeating and capturing the stranded foe.

In 424 Demosthenes made an abortive attack on Megara and launched an unsuccessful invasion of Boeotia. In 413 he was sent to reinforce the general Nicias during the Athenian siege of Syracuse. Failing in a night attack on the high ground overlooking the city, Demosthenes advised immediate retreat but was overruled by Nicias. When the retreat finally began, the division under Demosthenes fell behind and was forced to surrender. Demosthenes was put to death by his captors.

Demosthenes (b. 384 BC, Athens—d. Oct. 12, 322, Calauria, Argolis), Athenian statesman, recognized as the greatest of ancient Greek orators, who roused Athens to oppose Philip of Macedon and, later, his son Alexander the Great. His speeches provide valuable information on the political, social, and economic life of 4th-century Athens.

Heritage and youth. Demosthenes, a contemporary of Plato and Aristotle, was the son of a wealthy sword maker. His father died when he was seven, leaving a large inheritance, but the boy's unscrupulous guardians took advantage of their position, and when he came of age Demosthenes received very little of his estate. His strong desire to sue his guardian, Aphobus, in the courts, coupled

Demosthenes, marble statue, detail of a Roman copy of a Greek original of c. 280 BC; in the Ny Carlsberg Glyptotek, Copenhagen

with a delicate physique that prevented him from receiving the customary Greek gymnastic education, led him to train himself as an orator. He also studied legal rhetoric. In his *Parallel Lives* Plutarch, the Greek historian and biographer, relates that Demosthenes built an underground study where he exercised his voice, shaving one half of his head so that he could not go out in public. Plutarch adds that Demosthenes had a speech defect, "an articulate and stammering pronunciation" that he overcame by speaking with pebbles in his mouth and by reciting verses when running or out of breath. He also practiced speaking before a large mirror.

Despite this self-improvement program, his first youthful speaking efforts in the public Assembly met with disaster: he was laughed at by his audiences. His lawsuits against Aphobus and two other guardians in 363 were more successful; they produced little money, but he learned much about speaking strategy and methods of argument. Three of his speeches against Aphobus and two against the sculptor Antenor have survived.

Demosthenes as speech writer. At the age of 20 the young Demosthenes found himself without his fortune, without a trade or profession, and with seemingly little prospect for success in any field. But his rhetorical skill had been noticed. In 4th-century democratic Athens every citizen who wished to prosecute a lawsuit or to defend himself against accusation had to do the speaking himself. Not every citizen, of course, possessed sufficient skill to write his own speeches—a fact that gave rise to the practice of employing a speech writer (logographer) to prepare a speech for such occasions. Demosthenes' skill in his speeches against Aphobus was recognized by wealthier men in need of a logographer; he soon acquired wealthy and powerful clients willing to pay well for his services. Thus began a lifelong career that he continued even during his most intense involvement in the political struggle against Philip of Macedon, much as a modern lawyer might retain a private practice while engaged in public affairs.

Demosthenes was already 30 when, in 354, he made his first major speech before the Assembly. The speech, "On the Navy Boards," was a marked success. The Assembly or Ecclesia (Ekklesia), a legislative body composed of all adult male Athenian citizens, had convened to consider a rumoured threat against Athens by the King of Persia. Demosthenes' tightly reasoned oration helped persuade the Athenians to build up their naval strength quietly to show the Persians that, though Athens

would not launch an attack, it was ready to fight. He pointed out that, while Athens would have no allies if it attacked first, every other Greek city-state would join Athens if the Persians were the first to attack. Here, for the first time, Demosthenes sounded a theme that was to run through his whole public career—the policy that Athens could best keep its democratic freedom by remaining independent of all other cities while, on the other hand, being ready to make temporary alliances whenever danger threatened. In the same speech, revealing his penchant for careful fiscal planning, he proposed an elaborate revision of the method used to tax the wealthy to raise money for ships.

Leader of the democratic faction. From this point on (354), Demosthenes' career is virtually the history of Athenian foreign policy. It was not very long before his oratorical skill made him, in effect, the leader of what today might be called the democratic party. Some interests, especially the wealthy, would have preferred an oligarchy instead of a democracy; many merchants would have preferred peace at almost any price. While they agreed that the Macedonians were barbarians, most Athenian citizens distrusted other Greek city-states such as Thebes and Sparta. The Athenian Assembly was a loosely organized, often tumultuous body of up to 6,000 male citizens; it was capable of shouting down a speaker it did not like or of routing him with laughter. Any citizen could speak, but the criteria were so high that only the best orators survived for long. In this turbulent arena Demosthenes stood out. Contemporaries refer to him as "a water drinker"; that is, a severe and perhaps forbidding personality. Although name-calling was common practice in the Assembly, Demosthenes' wit was exceptionally caustic; when defending himself in his speech "On the Crown" against the attacks of his lifelong rival, Aeschines, he did not scruple to call him "sly beast," "idle babbler," "court hack," and "polluted." Demosthenes was not merely better at abuse than most; he also realized the advantage of making an audience lose respect for his opponent.

He was an assiduous student of Greek history, using detailed historical parallels in almost all his public speeches, and reportedly copied out Thucydides' *History of the Peloponnesian War* eight times in order to improve his command of language and to absorb its history. He constantly asked the Athenians to recall their own history, to remember their past belief in democracy, and to remind themselves how much they hated tyrants. His love of democracy gives his speeches a humanistic breadth that makes them interesting even today. Demosthenes was also extremely industrious. Plutarch says that it was his habit to sit down at night and go over the conversations and speeches he had heard during the day, experimenting with various replies or speeches that could have been made. He excelled whenever he could prepare his speeches carefully in advance, but the nature of Athenian political life must often have forced him to reply to an opponent on the spur of the moment. Unfortunately, because all of the surviving speeches are carefully edited texts, it cannot be established how often Demosthenes spoke extemporaneously.

His famous speech in 354 "On the Navy Boards" was addressed to the threat from the East. Meanwhile, in Macedonia, to the north, the young king Philip, almost the same age as Demosthenes, was gradually annexing Greek cities south of his borders. In 356 Philip had captured an Athenian possession in Thrace, after hoodwinking the Athenians with promises to protect the city, and in 354 he took another Athenian possession. By 353 both Sparta and Arcadia were asking Athens for military assistance against Philip. When he continued

to move south, employing bribery and threat as well as military force, the Athenians sent a small force to close off the pass at Thermopylae. Although Philip turned aside to the coast of Thrace, avoiding a direct confrontation with Athens, his intentions were clear. Yet many Athenians continued to believe that Philip's threat was transitory.

The Philippics. Early in 351 Demosthenes delivered a speech against Philip, the so-called "First Philippic," that established him as the leader of the opposition to Macedonian imperial ambitions. For the next 29 years Demosthenes never wavered; as Plutarch says, "The object which he chose for himself in the commonwealth was noble and just, the defense of the Grecians against Philip." In the "First Philippic" he reminded the Athenians that they had once defeated the Spartans, who were as strong as Philip, and sarcastically pointed out that Philip would never have conquered their territories if he had been as timid as the Athenians seemed to be. He concluded by challenging his countrymen to take their affairs in their own hands rather than let Philip win by default.

This goading speech nonetheless failed to rouse the Athenians. Philip advanced into Chalcidice, threatening the city of Olynthus, which appealed to Athens. In 349 Demosthenes delivered three stirring speeches (the "Olynthiacs") to elicit aid for Olynthus, but the city fell the following year without significant help from Athens. Finally, Philip and the Athenians agreed in April 346 to the Peace of Philocrates; Demosthenes, partly to gain time to prepare for the long struggle he saw ahead, agreed to the peace and went as one of the ambassadors to negotiate the treaty with Philip. During the negotiations, Philip, recognizing Demosthenes' eloquence as a threat to his plans, ignored him and addressed his fellow ambassador Aeschines instead. The two men returned from the embassy bitter foes, Demosthenes denouncing Aeschines and Aeschines assuring everyone of Philip's good intentions.

In his oration "On the Peace" late in 346 Demosthenes, though condemning the terms of the treaty of Philocrates, argued that it had to be honoured. Meanwhile, Philip continued his tactic of setting the Greek city-states, such as Thebes and Sparta, against each other. Demosthenes was one of several ambassadors sent out on a futile tour of the Peloponnese to enlist support against Philip. In retaliation Philip protested to Athens about certain statements made by these ambassadors. Demosthenes' "Second Philippic," in 344, retorted that he would never have agreed to the Peace of Philocrates if he had known that Philip would not honour his word; moreover, he asserted, Aeschines and others had lulled the Athenians into a false sense of security. The issue came to a public trial in the autumn of 343, when Demosthenes, in his speech "The False Legation," accused Aeschines of rendering false reports, giving bad counsel, disobeying instructions, and being susceptible to bribery. The court, however, acquitted Aeschines.

The tangled pattern of threat and counter-threat continued into 341, until an Athenian general incurred Philip's wrath for operating too near one of his towns in the Chersonese. Philip demanded his recall, but Demosthenes replied in a speech, "On the Chersonese," that the motive behind the Macedonian's "scheming and contriving" was to weaken the Athenians' will to oppose Philip's conquests. "Philip is at war with us," he declared, "and has broken the peace." Shortly afterward, Demosthenes delivered his "Third Philippic," perhaps the most successful single speech in his long campaign against Philip. As a result, Demosthenes became controller of the navy and could thus carry out the naval reforms he had proposed in 354. In addition, a grand alliance was formed against Philip,

including Byzantium and former enemies of Athens, such as Thebes. Indecisive warfare followed, with Athens strong at sea but Philip nearly irresistible on land. The Macedonian army was well organized under a single brilliant commander who used cavalry in coordination with highly disciplined infantry, while the Greek alliance depended upon what was essentially a group of citizens' militia.

Disaster came in 338, when Philip defeated the allies in a climactic battle at Chaeronea in north-central Greece. According to Plutarch, Demosthenes was in the battle but fled after dropping his arms. Whether or not he disgraced himself in this way, it was Demosthenes whom the people chose to deliver the funeral oration over the bodies of those slain in the battle. After the peace concluded by the Athenian orator and diplomat Demades, Philip acted with restraint; and, though the pro-Macedonian faction was naturally greatly strengthened by his victory, he refrained from occupying Athens. Demosthenes came under several forms of subtle legislative attack by Aeschines and others.

In 336 Greece was stunned by the news that Philip had been assassinated. When his son Alexander succeeded him, many Greeks believed that freedom was about to be restored. But within a year Alexander proved that he was an even more implacable foe than his father—for, when the city of Thebes rebelled against him in 335, he destroyed it. A string of victories emboldened Alexander to demand that Athens surrender Demosthenes and seven other orators who had opposed his father and himself; only a special embassy to Alexander succeeded in having that order rescinded. Shortly thereafter, Alexander began his invasion of Asia that took him as far as India and left Athens free of direct military threat from him.

In 330, nevertheless, judging that the pro-Alexandrian faction was still strong in Athens, Aeschines pressed his charges of impropriety against Ctesiphon—first made six years earlier—for proposing that Demosthenes be awarded a gold crown for his services to the state. The real target was, of course, Demosthenes, for Aeschines accused Ctesiphon of making a false statement when he praised the orator's patriotism and public service. The resulting oratorical confrontation between Aeschines and Demosthenes aroused interest throughout Greece, because not only Demosthenes but also Athenian policy of the past 20 years was on trial. A jury of 500 citizens was the minimum required in such cases, but a large crowd of other Athenians and even foreigners flocked to the debate.

Delivery of "On the Crown." The oration "On the Crown," Demosthenes' reply to Aeschines' charges of vacillating in his policy, accepting bribes, and displaying cowardice in battle, is universally acknowledged as a masterpiece of rhetorical art. It covers the entire two decades of Greek involvement with Philip and Alexander, contrasting Demosthenes' policies in every case with what he terms the treachery of Aeschines as an agent of the Macedonians. As always, his command of historical detail is impressive. Over and over again he asks his audience what needed to be done in a crisis and who did it. Addressing Aeschines directly, he says, "Your policies supported our enemy, mine, our country's." His scathing epithets picture Aeschines as a contemptible turncoat, a hireling of Philip. The jury's verdict was resoundingly clear—Aeschines failed to receive even one-fifth of the votes and was thus obliged to go into exile. Demosthenes and his policies had received a massive vote of popular approval.

Imprisonment and exile. Six years later, however, he was convicted of a grave crime and forced to flee from prison and himself go into exile. He was accused of taking 20 talents deposited in Athens by Harpalus, a

refugee from Alexander. Demosthenes was found guilty, fined 50 talents, and imprisoned. The circumstances of the case are still unclear. Demosthenes may well have intended to use the money for civic purposes, and it is perhaps significant that the court fined him only two and one-half times the amount involved instead of the 10 times usually levied in such cases. His escape from prison made it impossible for him to return to Athens to raise money for the fine. The onetime leader of the Athenians was now a refugee from his own people.

Another dramatic reversal occurred the very next year, however, when Alexander died. The power of the Macedonians seemed finally broken; a new alliance was concluded against them. The Athenians recalled Demosthenes from exile and provided money to pay his fine. But at the approach of Antipater, Alexander's successor, Demosthenes and other orators again fled the city. His former friend Demades then persuaded the Athenians to sentence Demosthenes to death. While fleeing Antipater's soldiers, he killed himself by taking poison. Following his long service to the state, which nonetheless ended in abandonment by the fickle Athenian citizenry, Demosthenes' death can be viewed as a symbol of the decline of Athenian democracy.

Influence and reputation. For almost 30 years Demosthenes rallied the citizens of Athens to oppose the military power of Philip of Macedonia and Philip's son Alexander the Great. Demosthenes' speech "On the Crown," the defense of his career delivered in 330, has been termed "the greatest speech of the greatest orator in the world." In the century following his death, the scholars at the Library of Alexandria carefully edited the manuscripts of his famous speeches. His fame was such that, when the Roman orator Cicero delivered a series of speeches in 44 BC opposing Mark Antony, in circumstances not unlike those in which Demosthenes opposed Philip, Cicero's speeches were called Philippics too. Roman schoolboys studied Demosthenes' speeches as part of their own oratorical training. During the Middle Ages and Renaissance, his name was a synonym for eloquence. Modern scholars such as Werner Jaeger present a more dispassionate view by pointing to the highly complex political issues that Demosthenes handled with his oratorical skill. Whatever the interpretation of his personality and work, he has in every age been regarded as one of the world's greatest orator-statesmen.

(J.J.M./Ed.)

BIBLIOGRAPHY. Werner Jaeger, *Demosthenes: The Origin and Growth of His Policy* (1938, reissued 1977), offers a balanced view of his life and policies. James J. Murphy (ed.), *Demosthenes' On the Crown: A Critical Case Study of a Masterpiece of Ancient Oratory* (1967, reprinted 1983), includes Plutarch's biography, an analysis by George Kennedy of Demosthenes' oratorical career, a translation of his speech "On the Crown," and analyses of his use of style, argument, and historical detail.

Demotic Greek language, also called **ROMAIC**, Greek **DEMOTIKI**, or **ROMAIKI**, a modern vernacular of Greece. In modern times it has been the standard spoken language and, by the 20th century, had become almost the sole language of Greek creative literature. In January 1976, by government order, it became the official language of the state, replacing Katharevousa Greek (*q.v.*) as the language for governmental and legal documents, in the courts and Parliament, in the schools, and in newspapers and other publications. (Katharevousa continued to be used in some legal documents and other technical writings in which there was a large body of established literature.)

Although the vocabulary, phonology, and grammar of ancient Greek remain the basis of Demotic Greek, they have been considerably modified and simplified. Foreign words and constructions that penetrated the language in large numbers reflect the influence of various foreign powers that held sway in postclassical Greece or that exerted influence there, from the foundation of the eastern Roman Empire (AD 325) through the Crusades to the Venetian and Turkish conquests. The Turkish domination, in particular, destroyed Greek literary continuity and development, and after Greece regained its independence in the early 19th century, many nationalists—wishing to meet the need for a uniform written language—developed an artificial, purified language, Katharevusa, as an approximation of the old classical norms. It was a deliberate archaization. When a military dictatorship arose in 1967, the new conservatism extended to language, and Katharevusa was strictly imposed in the schools. But after the restoration of political democracy in 1974, linguistic democracy followed suit, and Demotic—literally, the “popular” language—was given official sanction.

Today the two varieties, Demotic and Katharevusa, have merged to form a single unified language, Standard Modern Greek (Greek: Koini Neoelliniki).

demotic script, Egyptian hieroglyphic writing of cursive form that was used in handwritten texts from the early 7th century BC until the 5th century AD. Demotic script derived from the earlier pictographic hieroglyphic inscriptions and the cursive hieratic script (*q.v.*), and it began to replace hieratic writing during the reign of Psamtik I (664–610 BC). By the 5th century BC, demotic script had come into use everywhere in Egypt for business and literary purposes, although hieratic remained in use for religious texts. The demotic script began to be displaced by Greek during the Ptolemaic period (304–30 BC), but hieratic graffiti left by the priests of Isis at Philae date from as late as AD 452.

Dempsey, Jack, byname of WILLIAM HARRISON DEMPSEY, also called MANASSA MAULER (b. June 24, 1895, Manassa, Colo., U.S.—d. May 31, 1983, New York, N.Y.), American world heavyweight boxing champion, regarded by many as the apotheosis of the professional fighter. He held the title from July 4, 1919, when he knocked out Jess Willard in three rounds in Toledo, Ohio, until Sept. 23, 1926, when he lost a 10-round decision to Gene Tunney in Philadelphia.

Dempsey started boxing in 1914 under the name Kid Blackie. In 1918 and early 1919 he compiled an impressive number of knockouts, most in the first round, to earn a fight with Willard. The 37-year-old champion proved no match for young Dempsey, who attacked ferociously from the starting bell and knocked Willard to the floor seven times in the first round. Even more primitive in its intensity was Dempsey's title defense against Argentine heavyweight Luis Angel Firpo in New York City on Sept. 14, 1923. After being knocked out of the ring in the first round, Dempsey battered Firpo into defeat in the second.

During the next three years Dempsey fought only exhibition matches, and, at the age of 31, he found that he had aged too much to deal with the carefully trained Tunney in their first fight. On Sept. 22, 1927, in Chicago, they met again in the famous “Battle of the Long Count,” in which Dempsey forfeited his chance for a seventh-round knockout by standing over the fallen Tunney rather than going to a neutral corner of the ring. Tunney recovered to win another 10-round decision. In his boxing style, Dempsey kept on the of-

Dempsey

fensive almost continuously, bobbing up and down and moving from side to side as he delivered short, swinging blows out of a crouch at blinding speed. His constant movement and the speed of his attack constituted his defense.

In the 1930s Dempsey appeared in many exhibitions but was never again a serious contender for the championship. In 1940 he had three knockout victories over unknown opponents before retiring to referee boxing and wrestling matches. In World War II he served as a lieutenant commander in the Coast Guard. From 1914 to 1940 he had 84 bouts, winning 62, 51 by knockouts. He eventually became a successful restaurateur in New York City. His autobiography was published in 1977.

Dempster, Arthur Jeffrey (b. Aug. 14, 1886, Toronto, Ont., Can.—d. March 11, 1950, Stuart, Fla., U.S.), American physicist who built the first mass spectrometer, a device used to separate and measure the quantities of different charged particles, such as atomic nuclei or molecular fragments.

Dempster was educated at the University of Toronto (A.B., 1909; M.A., 1910) and then studied in Germany. He went to the United States in 1914 and obtained his doctorate in physics at the University of Chicago in 1916. He built his first mass spectrometer in 1918, and he began teaching at the University of Chicago in 1919. In 1936, with Kenneth T. Bainbridge of the United States and J.H.E. Mattauch of Austria, he developed a double-focusing type of mass spectrograph, a device used to measure the mass of atomic nuclei. Dempster devoted much of his career almost exclusively to a single task—that of using mass spectrometry techniques to discover stable isotopes of the chemical elements and their relative abundances. He discovered more such isotopes than anyone except Francis William Aston, the inventor of the mass spectrograph. Dempster discovered the isotope uranium-235, which is used in atomic bombs.

Demre (Turkey): *see* Myra.

demurrer, in law, process whereby a party admits as true certain facts alleged by the opposition but asserts that they are not sufficient grounds for relief, or redress. A ruling on a demurrer can result in the quick disposition of a case resting on the point of law challenged in the demurrer.

In criminal law a demurrer is usually based upon some defect in the indictment or the claim that the facts presented do not constitute a felony or serious crime. In civil cases demurrers are also often based upon some error or omission. A general demurrer attacks the general substance of an indictment or plea; a

special demurrer attacks its structure or form or one specific part of it.

Demuth, Charles (b. Nov. 8, 1883, Lancaster, Pa., U.S.—d. Oct. 23, 1935, Lancaster), painter who helped channel modern European movements into American art and who was also a leading exponent of Precisionism (*q.v.*).

Demuth's early training was under Thomas Anshutz and W.M. Chase at the Pennsylvania Academy of the Fine Arts. Between 1907 and 1913 Demuth made several trips to Europe to study, and while in Paris he was attracted by the work of Marcel Duchamp and the Cubists, influences that lasted throughout his career. After returning to the United States, he illustrated works by several of his favourite authors. Moving gradually away from illustrative art, he executed a series of watercolours of flowers, circuses, and café scenes that placed him in the first rank of watercolourists of his period. Late in his career, Demuth began to paint advertisements and billboards into such cityscapes as his “Buildings, Lancaster” (1930), in which bold, commercial lettering is complemented by the severely hard-edged ab-

“I Saw the Figure 5 in Gold,” oil on composition board by Charles Demuth, 1928; in the Metropolitan Museum of Art, New York City

straction of buildings. Among Demuth's best-known works are his poster portraits such as the tribute to the poet William Carlos Williams, “I Saw the Figure 5 in Gold.”

Den Bosch (The Netherlands): *see* 's Hertogenbosch.

Denakil Plain, also spelled DANAKIL, also called DANKALI, arid lowland of northern Ethiopia and southeastern Eritrea, bordering Djibouti. It lies at the northern extreme of the Great Rift Valley and the Awash River. Live volcanoes (often called the Denakil Alps) separate it from the Red Sea. Any water that comes into the plain evaporates there; no streams flow out from it. The Kobar Sink, a huge basin in the northern part of the plain, drops to 381 feet (116 m) below sea level. The Denakil Plain was formed by the evaporation of an inland sea. About 450 square miles (1,200 square km) is covered by salt; salt reserves are estimated at more than 1,000,000 tons (1,120,000 metric tons). The salt is cut into bars and carried by mule to other parts of Ethiopia and Eritrea. Nomadic pastoralists, related to the Afar people of Djibouti, are virtually the plain's only inhabitants. In the southern part of the plain, in Ethiopia, lies the Mille-Sardo Wildlife Reserve (1973), which covers 3,385 square miles (8,766 square km).

Denali National Park and Preserve, park and preserve in central Alaska, U.S., established in 1980 from the former Mount McKinley National Park (1917) and Denali National

Monument (1978). Denali ("The Great One") is the ancient Athapascan Indian name for Mount McKinley, the highest mountain in North America at 20,320 feet (6,194 m). Highlights of the park include the large glaciers of the Alaska Range. The park's total area is 7,409 square miles (19,189 square km).

Denbighshire, Welsh SIR DDINBYCH, county of northern Wales extending inland from the Irish Sea coast. The present county of Denbighshire includes the Vale of Clwyd along the River Clwyd and an inland area between the Clwydian Range in the east and the Cllocaenog Forest in the west that ascends to the Berwyn mountains in the south. The lower Vale of Clwyd and the seacoast are part of the historic county of Flintshire (Sir Fflint). The southernmost portion of the present county, bordering the Berwyn range, belongs to the historic county of Merioneth (Meirionnydd). The remaining central portion of the present county constitutes only a part of the historic county of Denbighshire, which also encompasses the eastern portion of the county borough of Conwy, most of the county borough of Wrexham, and a small northern section of the county of Powys.

The Vale of Clwyd and the upper reaches of the River Dee have been focuses of human settlement since ancient times. The discovery of the hill fort of Pen-y-Corrdyn in the hills just south of the village of Llanddulas provides evidence of Iron Age settlement. An important ancient route along the North Wales coast passed through the historic county of Denbighshire, which was the site of two Roman roads. Evidence indicates that the Romans mined lead in the area. In the southeast is a section of Offa's Dyke, an earthwork that marked the boundary between Wales (west) and England (east). Among the county's medieval monuments is the beautiful, ruined Valle Crucis Abbey (founded by the Cistercians c. 1200), near Llangollen.

Tourism is the area's main industry. Prestatyn and Rhyl are seaside resorts. Area present county, 324 square miles (839 square km). Pop. (1998 est.) present county, 90,500.

Dench, Dame Judi, original name in full JUDITH OLIVIA DENCH (b. Dec. 9, 1934, York, North Yorkshire, Eng.), British actress known for her numerous and varied stage roles, for her work in television, and for her supporting parts in a variety of films.

Dench studied at the Central School of Speech Training and Dramatic Art in London. In 1957 she gave her first important critically acclaimed performance, as Ophelia in the Old Vic production of *Hamlet*. Her performance as Lady Macbeth in the Royal Shakespeare Company's *Macbeth* (1977) earned her the best actress award from the Society of West End Theatre Managers (now the Society of London Theatre)—one of her many acting awards.

Among Dench's notable television credits were two BBC television series: *A Fine Romance* (1981-84), which she starred in with her husband since 1971, Michael Williams (died 2001), and the romantic comedy series *As Time Goes By* (from 1992). She also performed in many plays adapted for television and in such films as *A Room with a View* (1986) and *A Handful of Dust* (1988). She took the role of James Bond's boss, M, in the films *GoldenEye* (1995), *Tomorrow Never Dies* (1997), and *The World Is Not Enough* (1999) and played two British queens, the recently widowed Queen Victoria in *Mrs. Brown* (1997) and Queen Elizabeth I in the comedy *Shakespeare in Love* (1998). For *Mrs. Brown*, she won an Academy Award nomination and the Golden Globe Award for best actress in a drama. Dench was created O.B.E. in 1970 and advanced to D.B.E. in 1988.

Dendera (Egypt): see Dandarah.

dendrochronology, or TREE-RING DATING, the scientific discipline concerned with dating and interpreting past events, particularly paleoclimates and climatic trends, based on the analysis of tree rings. Samples are obtained by means of an increment borer, a simple metal tube of small diameter that can be driven into a tree to get a core extending from bark to centre. This core is split in the laboratory, the rings are counted and measured, and the sequence of rings is correlated with sequences from other cores.

Dendrochronology is based on the fact that many species of trees produce growth rings during annual growing seasons. The width of the ring (i.e., the amount of growth) for each year is determined by various internal and external factors, but it tends to vary mainly in proportion to either the amount of available precipitation or the prevailing temperatures. The ring measurements taken from trees with overlapping ages can extend knowledge of climates back thousands of years. California's bristlecone pines are particularly suitable for such chronologies, since some individual trees are more than 4,000 years old.

dendrogram: see phylogenetic tree.

Deneb (Arabic: "Tail" [of the Swan, Cygnus]), also called ALPHA CYGNI, one of the brightest stars, with an apparent magnitude of 1.26. This star is, at about 1,400 light-years' distance, one of the most remote (thus one of the brightest intrinsically) of the 20 apparently brightest stars. It lies in the northern constellation Cygnus.

Deng Xiaoping, Wade-Giles romanization TENG HSIAO-P'ING (b. Aug. 22, 1904, Szechwan province, China—d. Feb. 19, 1997, Peking [Beijing]), Chinese communist leader who was the most powerful figure in China from the late 1970s until his death in 1997. He abandoned many orthodox communist doctrines and introduced elements of the free-enterprise system into the Chinese economy.

Deng Xiaoping, 1979

© Moore/Gamma Liaison

The son of a landowner, Deng studied in France (1921-24), where he became active in the communist movement, and in the Soviet Union (1925-26). Back in China, he became a leading organizer in the Kiangsi Soviet, an autonomous communist enclave in southwestern China that Mao Zedong had established, and he participated in the Long March (q.v.; 1934-35). After serving as the commissar (political officer) of a division of the communists' Eighth Route Army (1937-45), he was appointed a secretary of the Central Committee of the Chinese Communist Party (CCP) in

1945 and was chief commissar of the communists' Second Field Army during the Chinese Civil War (1948-49). After the communist takeover of China in 1949, he became the regional party leader of southwestern China. In 1952 he was summoned to Peking and made a vice-premier. Rising rapidly, he became general secretary of the CCP in 1954 and a member of the ruling Political Bureau in 1955.

From the mid-1950s Deng was a major policy maker. He became closely allied with such pragmatist leaders as Liu Shaoqi, who stressed the use of material incentives and the formation of skilled elites to manage China's economic development. Deng thus increasingly differed with Mao, who stressed egalitarian policies and revolutionary enthusiasm as the key to economic growth.

In the early years of the Cultural Revolution (1966-76), Deng was stripped of his high party and government posts, and he disappeared from public view. In 1973, however, Deng was reinstated under the sponsorship of Premier Zhou Enlai and made deputy premier, and in 1975 he became vice-chairman of the party's Central Committee, a member of its Political Bureau, and chief of the general staff. As effective head of the government during the months before Zhou's death, Deng was widely considered his likely successor. But the (Maoist) Gang of Four managed to purge Deng from the leadership once again. Not until Mao's death in September 1976 and the consequent fall from power of the Gang of Four was Deng once more rehabilitated, this time with the assent of Mao's chosen successor to the leadership of China, Hua Guofeng.

By July 1977 Deng had returned to his high posts. He soon struggled with Hua for control of the party and government. Deng's superior political skills and broad base of support soon led Hua to surrender the premiership and the chairmanship to two of Deng's protégés in 1980-81: Zhao Ziyang became premier of the government, and Hu Yaobang general secretary of the CCP.

From this point on, Deng carried out his own policies for the economic development of China. Operating through consensus, compromise, and persuasion, Deng engineered important reforms in virtually all aspects of China's political, economic, and social life. His most important social reform was the institution of the world's most rigorous family-planning program. He instituted decentralized economic management and rational and flexible long-term planning to achieve efficient and controlled economic growth. China's peasant farmers were given individual control over and responsibility for their production and profits, a policy that greatly increased agricultural production within a few years of its initiation in 1981. Deng stressed individual responsibility in the making of economic decisions, material incentives as the reward for industry and initiative, and the formation of cadres of skilled, well-educated technicians and managers to spearhead China's development. He freed many industrial enterprises from the control of the central government and gave factory managers the authority to determine production levels and to pursue profits. In foreign affairs, Deng strengthened China's trade and cultural ties with the West and opened up Chinese enterprises to foreign investment.

Deng eschewed the most conspicuous leadership posts, but he was a member of the powerful Standing Committee of the Political Bureau, and he retained control of the armed forces as chairman of the CCP's Central Military Commission. He was also a vice-chairman of the CCP. He remained China's chief policy maker throughout the 1980s. In 1987 Deng stepped down from the CCP's Central

Committee, thereby relinquishing his seat on the Political Bureau and its dominant Standing Committee. By so doing he compelled similar retirements by many aged party leaders who had remained opposed or resistant to his reforms.

Deng faced a critical test of his leadership in April–June 1989. Zhao had replaced the too-liberal Hu as general secretary of the CCP in 1987. Hu's death in April 1989 sparked a series of student demonstrations in Tiananmen Square in Peking demanding greater political freedom and a more democratic government. After some hesitation, Deng supported those in the CCP leadership who favoured the use of force to suppress the protesters, and in June the army crushed the demonstrations with considerable loss of life. Zhao was replaced as party leader by the more authoritarian Jiang Zemin, to whom Deng yielded his chairmanship of the Military Commission in 1989. Though now lacking any formal post in the communist leadership, Deng retained ultimate authority in the party. Although his direct involvement in government declined in the 1990s, he retained his influence until his death.

Deng restored China to domestic stability and economic growth after the disastrous excesses of the Cultural Revolution. Under his leadership, China acquired a rapidly growing economy, rising standards of living, considerably expanded personal and cultural freedoms, and growing ties to the world economy. Deng also left in place a mildly authoritarian government that remained committed to the CCP's one-party rule even while it relied on free-market mechanisms to transform China into a developed nation.

dengue, also called **BREAKBONE FEVER**, or **DANDY FEVER**, acute, infectious, mosquito-borne hemorrhagic fever that temporarily is completely incapacitating but is rarely fatal. Besides fever, the disease is characterized by an extreme pain in and stiffness of the joints (hence the name "breakbone fever"). Dengue is caused by a virus and may occur in any country where the carrier mosquitoes breed.

The carrier incriminated throughout most endemic areas is the yellow-fever mosquito, *Aedes aegypti*. The Asian tiger mosquito, *A. albopictus*, is another prominent carrier of the virus. A mosquito becomes infected only if it bites an infected individual (humans and perhaps also certain species of monkey) during the first three days of the victim's illness. It then requires 8 to 11 days to incubate the virus before the disease can be transmitted to another individual. Thereafter, the mosquito remains infected for life. The virus is injected into the skin of the victim in minute droplets of saliva. The spread of dengue is especially unpredictable because there are four serotypes of dengue virus. Infection with one type—though it confers lifetime immunity from reinfection with that type of dengue—does not prevent an individual from being infected by the other three types.

Diagnosis is made on clinical findings, namely, sudden onset, moderately high fever, excruciating joint pains, intense pain behind the eyes, a second rise in temperature after brief remission, and particularly the type of rash and decided reduction in neutrophilic white blood cells. There is no specific therapy; therefore attention is focused on relieving the symptoms. Temporary preventive measures must be taken to segregate suspected as well as diagnosed cases during their first three days of illness and, by screens and repellents, to keep mosquitoes from biting more people.

The potentially fatal fever is prevalent in parts of Asia, and in the late 20th century it spread to areas of South and Central America

and to Cuba, Puerto Rico, and other nearby islands. Fundamental in the control of the disease is the destruction of mosquitoes and their breeding places.

Dengyō Daishi: see Saichō.

Denham, Dixon (b. Jan. 1, 1786, London, Eng.—d. May 8, 1828, Freetown, Sierra Leone), English soldier who became one of the early explorers of western Africa.

After serving in the Napoleonic Wars, Denham volunteered in 1821 to join Walter Oudney and Lieutenant Hugh Clapperton on an official expedition across the Sahara to Bornu (now in northeastern Nigeria), in the Lake Chad basin. After enduring danger and privation, they arrived at Kuka, the capital of Bornu, on Feb. 17, 1823. In December 1823, while Clapperton and Oudney set out on a journey westward, Denham explored the

Dixon Denham, detail from an oil painting by T. Phillips, 1826; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

shores of Lake Chad and the lower courses of the Waubé, Chari, and Logone rivers. Returning to England in 1825, Denham became a celebrity. He was promoted to lieutenant colonel and appointed superintendent of liberated slaves in West Africa in 1827. The next year he was made governor of Sierra Leone, where he died of fever.

Denham, Sir James Steuart, 4TH BARONET, original name (until 1773) JAMES STEUART (b. Oct. 21, 1712, Edinburgh, Scot.—d. Nov. 26, 1780, Edinburgh), Scottish economist whose exposition of mercantilist views showed a sophistication ahead of his time.

Denham was educated at the University of Edinburgh (1724–25). In the course of continental travels following his qualification as a lawyer (1735), he became embroiled in the Jacobite cause. Denham's involvement in the 1745 rebellion of the Stuart pretender to the throne forced him to remain in exile until 1763, when he finally returned to Edinburgh. He then retired to Coltness. In 1773 his father obtained the estates of his uncle, Sir Archibald Denham, on the condition that he and his father adopt Denham as a surname. In 1780 he succeeded his father in two baronetcies.

His chief work, *Inquiry into the Principles of Political Economy* (1767), is probably the first systematic treatise on economics in English. As an exponent of mercantilist economics, Denham accorded government a key role in the economic development of society, particularly in the management of population and employment. Government intervention was also desirable, in his view, to bring about market equilibrium. Consistent with his mercantilist views, Denham believed that an industrializing country would experience loss of international markets because of rising wages; thus, he believed that reliance upon internal markets was important. His theory of the role of money in economic growth remains of interest to contemporary economists.

Denham, Sir John (b. 1615, Dublin, Ire.—d. March 10, 1669, London, Eng.), poet who established as a new English genre the leisurely meditative poem describing a particular landscape.

Educated at the University of Oxford, Denham was admitted to the bar, but he was already actively writing. He had translated six books of the *Aeneid*, parts of which were later printed; but he made his reputation with *The Sophy*, a blank-verse historical tragedy acted in 1641, and with *Cooper's Hill*, a poem published in 1642. During the English Civil Wars, he was engaged at home and abroad in the cause of Charles II. Made a knight of the Bath and elected to the Royal Society after the Restoration in 1660, he also served as a member of Parliament. He was buried in Westminster Abbey.

Denham's poetry is essentially didactic. His strength is considered to lie in his thought, particularly his neatly turned expressions of ethical and moral truisms. He helped develop the closed heroic couplet (a couplet rhyming *aa* and containing a complete idea, not dependent upon the preceding or following couplet). Denham greatly increased the popularity of that form with *Cooper's Hill*, a new type of descriptive landscape verse that was imitated by English poets for the next 100 years.

denial of Not-Being (philosophy): see Not-Being, denial of.

Denikin, Anton Ivanovich (b. Dec. 16 [Dec. 4, Old Style], 1872, near Warsaw, Pol., Russian Empire—d. Aug. 8, 1947, Ann Arbor, Mich., U.S.), general who led the anti-Bolshevik ("White") forces on the southern front during the Russian Civil War (1918–20).

A professional in the Imperial Russian Army, Denikin served in the Russo-Japanese War (1904–05) and in World War I (1914–16). After the February Revolution of 1917, which overthrew the Romanov dynasty, he became chief of staff to the provisional government's commander in chief, Mikhail V. Alekseyev, but was quickly disillusioned by that government's inability to maintain discipline in the army. He was dismissed from his post in July for political reasons.

Placed in command of the western front, Denikin came into close contact with General Lavr G. Kornilov, then the Russian supreme military commander, and in August 1917 the two were arrested for conspiring to overthrow the provisional government and establish a military dictatorship. A month after the Bolsheviks' October (Old Style) coup d'état, however, they escaped from prison and fled southward to the Don River region, where Kornilov assumed command of the White Army recently formed by Alekseyev. Kornilov was killed in April 1918, and Denikin became commander of the White forces in southern Russia. By the beginning of 1919 he controlled the northern Caucasus; in May he launched a major offensive, advancing through Ukraine toward Moscow. In October, however, the Red Army defeated him at Oryol (250 miles [402 km] from Moscow) and forced him to retreat with his disintegrating army to Novorossiysk; the remainder of his army was then evacuated to the Crimea (March 1920). In April Denikin turned over his command to General Pyotr N. Wrangel and settled in France, where he wrote his memoirs, *Ocherki russkoy smuty*, 5 vol. (1923–27; "History of the Civil Strife in Russia"). He immigrated to the United States in 1945.

Deniliquin, chief town of the fertile southern Riverina region, south-central New South Wales, Australia, on the Edward River (a branch of the Murray), 22 miles (35 km) from the Victoria border. Established in 1845 by Benjamin Boyd as a personal holding, it was made a town in 1848 under the name Sandhills. Two years later it was officially gazetted

as Deniliquin, a corruption of the name of a local Aboriginal chief. It became a busy crossing point for livestock and was declared a municipality in 1868. It is now the commercial and administrative centre for various irrigation districts. The region is well known as merino sheep stud country and also supports beef cattle, lambs, rice, fruits, tobacco, and grains. The town's products include butter, cheese, cordials, processed seed, brick and plaster, fabricated iron and steel, and timber. Deniliquin lies at the junction of the Riverina and Cobb highways; it is also the terminus of a rail line from Echuca and is connected by air to Sydney (374 miles [602 km] northeast) and Melbourne. Pop. (1994 prelim.) 8,510.

denim, durable twill-woven fabric with coloured (usually blue) warp and white filling threads; it is also woven in coloured stripes. The name is said to have originated in the French *serge de Nîmes*. Denim is yarn-dyed and mill-finished and is usually all-cotton, although considerable quantities are of a cotton-synthetic fibre mixture. Decades of use in the clothing industry, especially in the manufacture of overalls and trousers worn for heavy labour, have demonstrated denim's durability. This quality also made denim serviceable for leisure wear in the late 20th century. *See also* jeans.

A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume

Denis, SAINT, Denis also spelled DENYS, Latin DIONYSIUS (b. Rome?—d. 258?, Paris; feast day: Western church, October 9; Eastern church, October 3), allegedly first bishop of Paris, a martyr and a patron saint of France.

According to St. Gregory of Tours's 6th-century *Historia Francorum*, Denis was one of seven bishops sent to Gaul to convert the people in the reign of the Roman emperor Decius. Little is known of his life; it is believed that he was martyred during the persecution of Christians by the Roman emperor Valerian. A legend recorded in the 9th century recounts that he was beheaded on Montmartre and that his decapitated corpse carried his head to the area northeast of Paris where the Benedictine abbey of St. Denis was founded. Denis is often portrayed in art as a decapitated (though evidently living) figure.

Denis THE LITTLE: *see* Dionysius Exiguus.

Denis, Maurice (b. Nov. 25, 1870, Granville, France—d. Nov. 13, 1943, Paris), French painter, one of the leading artists and theoreticians of the Symbolist movement.

Denis studied at the Académie Julian (1888) under Jules Lefebvre and at the École des Beaux-Arts. Reacting against the naturalistic tendencies of Impressionism, Denis fell under the influence of the work of Paul Gauguin, whose style was also much admired by Denis's fellow students Paul Sérusier, Édouard Vuillard, Pierre Bonnard, and Ker Xavier Roussel. With these friends, Denis joined in the Symbolist movement and its later offshoot, the group of painters collectively called the Nabis (*q.v.*). The quasi-mystical attitude of the Nabis was perfectly suited to Denis's highly religious nature. In 1890 Denis expressed the underlying principle of much modern painting in the following often-quoted words: "It should be remembered that a picture—before being a warhorse, a nude, or an anecdote of some sort—is essentially a flat surface covered with colours assembled in a certain order."

Later, however, after visiting Italy, Denis became greatly influenced by the works of the great Italian fresco painters of the 14th and 15th centuries and began to place emphasis on subject matter, traditional perspective, and modeling, as in "Homage à Cézanne" (1901).

Denis's monumental mural decorations are to be seen in many French churches as well as on the ceiling of the Champs Élysées Theatre

"The Muses," oil painting by Maurice Denis, 1893; in the National Museum of Modern Art, Paris

By courtesy of the Musée National d'Art Moderne, Paris, permission S.P.A.D.E.M. 1971. by French Reproduction Rights, Inc., photograph, Marc Garanger

in Paris. In 1919 he, along with Georges Devalières, founded the Studios of Sacred Art. His work was one of the chief forces in the revival of religious art in France.

Denishawn School of Dancing and Related Arts, dance school and company founded in 1915 by Ruth St. Denis and her husband, Ted Shawn. Considered a fountainhead of American modern dance, the Denishawn organization systematically promoted nonballetic dance movement and fostered such leading modern dancers as Martha Graham, Doris Humphrey, and Charles Weidman. Because St. Denis and Shawn believed that all dance techniques were valid and instructive, the school offered classes in Oriental, Spanish, and primitive dance; the fundamentals of ballet; their own innovative techniques; and, later, the modern-dance techniques that had been developed in Europe by Rudolf Laban and Émile Jaques-Dalcroze. Branches of the school were established in New York City and other American cities. The company's repertoire, choreographed by St. Denis and Shawn, ranged from unadorned solos to opulent productions with Japanese, Hindu, Middle Eastern, or American Indian themes. The Denishawn dancers frequently toured the United States and performed in the Orient (1925–26). The organization disbanded in 1931 after St. Denis and Shawn separated.

Denison, city, Grayson county, north-central Texas, U.S. Denison is situated near Sherman and Lake Texoma (impounded on the Red

Birthplace of President Dwight D. Eisenhower, Denison, Texas

By courtesy of the Texas Highway Department

River by Denison Dam) near the Oklahoma border, 73 miles (117 km) north of Dallas. Originally a stop on the Southern Overland Mail Route, it was organized by the Missouri-Kansas-Texas Railroad in 1872 as a division point and named for George Denison, a railroad director. Its economy is basically agricultural, augmented by light industry (chiefly clothing, aluminum, and plastic products), transportation, and tourism based on the Lake Texoma resort area, Hagerman National Wildlife Refuge, and Eisenhower State Park. The birthplace (1890) of President Dwight D. Eisenhower is preserved as a state historic site. Inc. 1891. Pop. (1994 est.) city, 21,498; Sherman-Denison MSA, 97,267.

denitrifying bacteria, microorganisms whose action results in the conversion of nitrates in soil to free atmospheric nitrogen, thus depleting soil fertility and reducing agricultural productivity. *Thiobacillus denitrificans*, *Micrococcus denitrificans*, and some species of *Serratia*, *Pseudomonas*, and *Achromobacter* are implicated as denitrifiers. *Pseudomonas aeruginosa* can, under anaerobic conditions (as in swampy or water-logged soils), reduce the amount of fixed nitrogen (as fertilizer) by up to 50 percent. Without denitrification, however, the Earth's supply of nitrogen would eventually accumulate in the oceans, since nitrates are highly soluble and are continuously leached from the soil into nearby bodies of water. *See also* nitrogen cycle.

Denizli, city, southwestern Turkey. It lies near a tributary of the Menderes River. Set among the gardens at the foot of Mount Gökbel (7,572 feet [2,308 m]), Denizli inherited the economic position of ancient Laodicea ad Lycum, 4 miles (6 km) away, when that town was deserted during wars between the Byzantines and the Seljuq Turks in the 12th century. By the 14th century, as Lâdik (Lâdiq), Denizli had emerged as an important Turkish town noted for its woven and embroidered products and its luxuriant gardens. It was ravaged by earthquakes in the 18th and 19th centuries.

In the surrounding agricultural area the cultivation of cotton, cereals, figs, and tobacco, along with livestock raising, are the principal activities. North of Denizli is Pamukkale (ancient Hierapolis), a resort around which limestone deposits from the hot springs have formed beautiful cascades and basins. Denizli is linked by a branch line to the Dinar-Izmir railway. Pop. (1990) 204,118.

Denmark, officially KINGDOM OF DENMARK, Danish KONGERIGET DANMARK, Faroese KONGARÍKIDJ DANMARK, Greenlandic DANMARKIP NĀLAGAUVFIA, a small country occupying a peninsula extending northward from the centre of continental western Europe and an archipelago to the east of the peninsula; in addition, Greenland and the Faroe (Faeroe) Islands are self-governing dependencies within the Danish realm.

Denmark extends for about 210 miles (335 km) from north to south and for about 180 miles (290 km) from east to west, when the eastern island of Bornholm is included. The country is a physical, cultural, and commercial bridge between Scandinavia and central Europe. Denmark's only landward neighbour is Germany, which lies to the south and with which it shares a border of only 42 miles (68 km). Denmark's 4,500-mile (7,300-kilometre) coastline (including the country's more than 400 islands) extends along the North Sea on the west, the Skagerrak (strait) on the north, and the Kattegat (strait), The Sound, and the Baltic Sea on the east. The capital is Copenhagen. Area (excluding Greenland and the Faroe Islands) 16,639 square miles (43,094 square km). Pop. (1995 est.) 5,223,000.

A brief treatment of Denmark follows. For full treatment, see *MACROPAEDIA: Denmark*.

For current history and for statistics on society and economy, see *BRITANNICA BOOK OF THE YEAR*.

Denmark

The land. The mainland of Denmark occupies the Jutland Peninsula; it is a lowland area, averaging less than 100 feet (30 m) above sea level, with its highest point only 568 feet (173 m) at Yding Forest Hill in east-central Jutland. The landscape derives its character from the northern European glaciations: a scenic moraine runs from Nissum Fjord on the western coast of Jutland eastward toward Viborg, turns southward, and continues the length of the country. The moraine demarcates the western Jutland region of sands and gravels from the fertile loam plains of eastern Jutland. The two largest islands of the Danish archipelago—Zealand (Sjælland, containing Copenhagen) and Funen (Fyn)—together constitute more than one-fourth of the country's total land area.

Denmark's largest river, the Gudenå, is 98 miles (158 km) long from its source in east-central Jutland to its mouth on the Randers Fjord on the eastern coast. Lake Arre, with an area of 15 square miles (40 square km), is the largest of the country's many small lakes.

The climate of Denmark is generally temperate and moist, with local annual rainfall ranging between 32 and 16 inches (800 and 400 mm). The mean annual variation in temperature is from about 32° F (0° C) in February to 61° F (16° C) in July.

Denmark's share of the North Sea's rich oil and natural-gas fields is smaller than that of the United Kingdom and Norway but is enough to supply about half the country's domestic needs. Denmark has almost no mineral reserves other than its large limestone and sand and gravel deposits.

The people. The modern population of Denmark is the result of an ethnic mixture that occurred in the Neolithic Period (New Stone Age). Blond hair and blue eyes predominate. Small but longstanding German, Jewish, and Polish minorities are largely assimilated. Among other minorities are Turks, South Slavs, Iranians, and Pakistanis, many of whom arrived as "guest workers."

The Danish language is a subdivision of the Germanic group and is closely related to Norwegian. The established religion, to which some 85 percent of the population belongs, is Evangelical Lutheran.

Denmark's population has grown only slightly in recent years owing to the general acceptance of family-planning practices. Life expectancy at birth is relatively high at 75 years for men and 79 years for women. Metropolitan Copenhagen has about one-fifth of the country's total population and, unlike Denmark's other major population centres of

Århus and Ålborg on Jutland and Odense on Funen, is not growing.

The economy. Despite the land's rather poor natural resources, the Danish population enjoys a standard of living equaled by only a few other countries in the world. Denmark has a mixed economy that is based on services, manufacturing, and financial services. The gross national product (GNP) is growing more rapidly than the population and is comparable to those of other Western industrialized countries.

More than one-half of Denmark's land is arable. Danish farming is intensive; most farms are medium-sized and family-owned. Wheat is the principal crop; barley, sugar beets, and potatoes are among the other major crops. Pastures occupy about one-twentieth of the land area, and livestock consists mainly of pigs, with lesser numbers of beef and dairy cattle. Chickens and other poultry are also important. Forests, including both natural broad-leaved deciduous and cultivated spruce and fir, occupy more than one-tenth of the land area. The division of Denmark into numerous islands has given it an exceptionally long coastline. The configuration of much of this coast into fjords provides natural harbours that encourage the fishing, shipping, and associated industries. Denmark's fishing (mostly marine) industry generally ranks among the top worldwide in total catch.

Denmark's rather small mining sector is based on feldspar and chalk. Most of the country's natural gas, crude petroleum, and petroleum products originate in the Danish oil fields of the North Sea.

Denmark's post-World War II industrialization program raised the demand for raw materials and energy fuels, such as oil and coal. The exploitation of oil deposits discovered in the North Sea in 1970, however, subsequently brought much relief from the cost of energy imports. Denmark's manufacturing is well developed and diversified, employing nearly one worker in three. The most important products are food products, nonelectrical machinery and apparatus, industrial chemicals and chemical products, metal products, and motor vehicles. Electricity is almost exclusively produced by thermal power plants.

Owing partly to a wide-ranging social-welfare program developed by the government, budgetary deficits have become a common feature of the nation's economy. More than one-fourth of the labour force is employed in social services. Unions are legal and completely free to organize and engage in union activity; they also administer the unemployment-insurance program for the government.

Tourism is important, bringing in many visitors, most of whom are attracted to Copenhagen and its neighbouring coastal resorts.

Denmark has an extensive road and highway system, and all roads are paved. A comparatively large railroad network was established during the last half of the 19th century. In the late 1990s work began on a fully automated subway system in Copenhagen, and the first link opened in 2002. Integral to the Danish transportation system are the numerous ferries and bridges. Of particular importance are the bridge and tunnel systems that connect Zealand with Funen (via the island of Sprogø) and Copenhagen with Malmö, Swed. Several bridges also connect Funen with Jutland. Denmark's many good harbours provide favourable conditions for numerous major shipping companies. The international airport is at Kastrup, southeast of Copenhagen.

Exports are primarily machinery, both nonelectrical and electrical, including electronic equipment, and ships and boats. The principal imports are food products, nonelectrical machinery, fuels and lubricants, and transport equipment. The principal trading partners are Germany, Italy, Slovakia, the United Kingdom, and France.

Government and social conditions. Denmark is a parliamentary state and constitutional monarchy whose crown retains only ceremonial power; the monarch's most significant duty is to appoint the prime minister and the members of the cabinet, who, however, are accountable to the Folketing, Denmark's unicameral legislature. The 179 members of the Folketing (including two from the Faroe Islands and two from Greenland) are elected by proportional representation. Under the 1953 constitution, the prime minister may dismiss the legislative body at any time and call for new elections. Denmark has a multiparty system. The Social Democratic Party (mainly representing workers and public servants) has been the country's dominant political organization, although a coalition of nonsocialist parties (the Conservative People's Party and the Liberal Party) held power for a decade beginning in 1982. The judicial system is headed by the Supreme Court.

The country has one of the world's oldest and most extensive social-welfare systems; it covers all citizens and provides benefits for old age, disability, maternity, death, and sickness. Its effectiveness, together with a high standard of living, have helped create excellent health conditions in Denmark.

Education in Denmark is compulsory for children between the ages of 7 and 16. Most schools are publicly operated and free. There are a number of universities, including the University of Copenhagen (founded 1479).

The news media in Denmark are free of censorship. Radio and television are operated by Danmarks Radio, an independent public institution supported by license fees on radio- and television-receiver owners.

Denmark has produced its share of internationally renowned writers, dancers, and visual artists. Among its great writers were Norwegian-born Ludvig Holberg, Hans Christian Andersen, and the philosopher-theologian Søren Kierkegaard. The Nobel Prize for Literature was awarded to the Danish novelist Henrik Pontoppidan in 1917 and Johannes V. Jensen in 1944. The Royal Danish Ballet became internationally famous through the 19th-century choreographic contributions of August Bournonville. The Royal Danish Academy of Fine Arts, established in 1754, produced the sculptor Bertel Thorvaldsen and in modern times the architect Arne Jacobsen.

History. Archaeological remains have shown evidence of human activity in Denmark as far back as 100,000 years ago. From 10,000 to 1500 BC, the population of Denmark progressed from an existence as hunters and fishers to a more settled lifestyle as agriculturists. About 2800 BC a single-grave culture emerged in the south and spread throughout Denmark. By approximately AD 400, political power was increasingly consolidated, and trading connections with the Romans had been established. The first runic inscription in Denmark dates roughly to AD 200; this writing system may have developed through contact with the Latin alphabet.

The northward extension of Charlemagne's Frankish empire in the late 8th century brought Denmark into close contact with the rest of Europe. The Frankish conquests were halted in the early years of the 9th century, and a treaty signed in 811 made the Eider River the frontier between Denmark and its neighbours to the south. The period of Viking expansion into the region began in the 7th century, and Christianity arrived in Denmark in the 10th century. Under King Canute, an Anglo-Danish empire came into being that included parts of Sweden and lasted until his death in 1035.

The medieval period of Danish history was marked by competition between the Danish nobility and would-be kings that resulted in the enforcement (in 1282) of the previously

conceived annual *hof* (parliament). During the 14th and 15th centuries Danish trade was hampered by the predominance of the German-dominated Hanseatic League. A union with Norway and Sweden came into existence in 1397, largely through royal-family intermarriage, and lasted until 1523, though there were intermittent periods of disunion and warfare between Denmark and Sweden beginning in 1448.

During the 16th century, civil war erupted in Denmark, bringing about the establishment of Lutheranism and the strengthening of the nobility. Denmark pursued a series of debilitating wars in the 17th century in an attempt to assert its hegemony over the Baltic. Mostly unsuccessful, the wars resulted in the Peace of Copenhagen (1660), which established the frontiers of Norway, Sweden, and Denmark at their present locations.

Economic hardships followed these costly wars, but some economic advances were made in the 18th century through expanded trade in colonial markets. The Napoleonic wars of the early 1800s again drained the treasury, and in 1814 Denmark had to cede Norway to Sweden. In 1864–66 Denmark lost Schleswig-Holstein to the Prussians.

Denmark went through three constitutions between 1849 and 1915, regained northern Schleswig by plebiscite in 1920, and was occupied by Nazi Germany in 1940–45.

In 1945 Denmark recognized the independence of Iceland, and in 1948 it granted home rule to the Faroe Islands, which had been part of Denmark since 1380. Greenland was officially incorporated into Denmark in 1953 and was granted home rule in 1979. Denmark was one of the founding members of NATO (1949), and it became a member of the European Community (now the European Union) in 1973.

Denmark, Evangelical Lutheran People's Church of: *see* Evangelical Lutheran People's Church of Denmark.

Denmark Strait, channel partially within the Arctic Circle, lying between Greenland (west) and Iceland (east). About 180 miles (290 km) wide at its narrowest point, the strait extends southward for 300 miles (483 km) from the Greenland Sea to the open waters of the North Atlantic Ocean. The cold East Greenland Current flows southward along the west side of the strait and carries icebergs, which originate in the Arctic Ocean and on the Greenland ice cap; a branch of the warmer Irminger Current flows northward near the Iceland coast.

Denmark's Aquarium, Danish DANMARKS AKVARIUM, largest aquarium in Denmark, located in Charlottenlund, outside of Copenhagen. It is noted for its collection of unusual fishes. Included among the more than 3,000 specimens of nearly 200 species of marine and freshwater fishes are lungfish, blind cave fish, mudskippers, and the primitive paddlefish from the United States. The aquarium also has some noteworthy exhibits featuring such marine invertebrates as sea anemones and octopuses.

Denmark's Aquarium was opened in 1939. It was expanded in 1974 to accommodate a set of landscape aquariums. The aquarium conducts research programs in fish physiology and parasitism that are supported by the Royal Danish Academy of Sciences.

Denner, Johann Christoph (b. Aug. 13, 1655, Leipzig [Germany]—d. April 20, 1707, Nürnberg, Bavaria), German maker of musical instruments and inventor of the clarinet.

Denner's father, Heinrich, made horns and animal calls; from him Christoph learned instrument building, at the same time becoming an excellent performer. His energy was mainly devoted to improving already existing woodwind instruments, and his well-tuned recorders, flutes, oboes, and bassoons were

highly regarded throughout Europe. He invented the clarinet sometime between 1690 and 1700, although other types of single-reed instruments had a long history and wide currency, especially in folk music. One of these, the chalumeau (a term also used for a double-reed instrument), was known to Denner; apparently his attempts to refine the chalumeau led to his invention of the clarinet. Denner's two sons continued the family tradition of instrument building.

Dennie, Joseph (b. Aug. 30, 1768, Boston, Mass. [U.S.]—d. Jan. 7, 1812, Philadelphia, Pa.), essayist and editor who was a major literary figure in the United States in the early 19th century.

Dennie graduated from Harvard College in 1790 and spent three years as a law clerk before being admitted to the bar in 1794. His practice failed to flourish, however, and in the meantime he had turned to writing. He and Royall Tyler formed a literary partnership under the pseudonyms Colon and Spondee, and together they began contributing satirical pieces to local newspapers. Between 1792 and 1802 Dennie wrote his periodical "Farrago" essays. For the *Farmer's Weekly Museum*, a well-known newspaper of Walpole, N.H., he wrote the series of graceful, moralizing "Lay Preacher" essays that established his literary reputation. He served as editor of the *Farmer's Weekly* from 1796 to 1798.

The strong pro-Federalist bias of Dennie's editorship and of his "Lay Preacher" essays secured him an appointment as personal secretary to Secretary of State Timothy Pickering in 1799. He thus moved to Philadelphia, but his job ended when Pickering was dismissed by President John Adams in 1800. Undaunted, Dennie, with Asbury Dickins, began in 1801 a politico-literary periodical called *The Port Folio*, which became the most distinguished literary weekly of its time in America. He contributed his own "Lay Preacher" essays and commissioned original manuscripts from Thomas Campbell, Leigh Hunt, and Thomas Moore, among other prominent writers and poets. As the founder of the Tuesday Club, Dennie was the centre of the aristocratic literary circle in Philadelphia and was for a time the leading literary arbiter in the country. He derided native American rusticity and crudity and opposed all democratic innovations while praising English literature, manners, and sophistication. He also advocated sound critical standards and encouraged such talented younger writers as Washington Irving.

Dennis, town ("township"), Barnstable county, southeastern Massachusetts, U.S., extending across Cape Cod. It includes the villages of Dennis Port, East Dennis, South Dennis, and West Dennis. Settled in 1639, it was a part of Yarmouth until 1793, when it was incorporated and named for the Reverend Josiah Dennis, pastor of the first meetinghouse. Clipper ships were once built in Shiverick Shipyard (East Dennis). Tourism and cranberry cultivation are economically important. The Cape Playhouse is a restored colonial meetinghouse and one of the best-known summer-stock theatres in the eastern United States. Historic sites include the Josiah Dennis Manse (1736) and Jericho House (1801). Pop. (1994 est.) 13,945.

Dennis, Eugene, original name FRANCIS XAVIER WALDRON, JR. (b. Aug. 10, 1905, Seattle, Wash., U.S.—d. Jan. 31, 1961, New York, N.Y.), American Communist Party leader and labour organizer. He was general secretary of the Communist Party of the United States of America (CPUSA) from 1945 to 1957 and national chairman during 1959–61.

Having worked at various trades in Seattle, Dennis joined the Industrial Workers of the World and in 1926 the Communist Party. Later he went to California to organize work-

ers, for which he was arrested numerous times. Jumping bail after a conviction in 1930, he spent several years in the Soviet Union and other countries. Returning to the United States in 1935, he began to rise in the hierarchy of the Communist Party. In 1949 he and 10 other Communist leaders were convicted of conspiring to advocate the violent overthrow of the government, for which Dennis served three years and nine months in prison. During his leadership of the Communist Party, Dennis supported the party's continued alignment with the Soviet Union.

Dennis, John (b. 1657, London, Eng.—d. Jan. 6, 1734, London), English critic and dramatist whose insistence upon the importance of passion in poetry led to a long quarrel with Alexander Pope.

Educated at Harrow School and the University of Cambridge, Dennis traveled on the European continent before settling in London, where he met leading literary figures. At first he wrote odes and plays, but, although a prolific dramatist, he was never very successful.

The most important of Dennis' critical works are *The Usefulness of the Stage* (1698), *The Advancement and Reformation of Modern Poetry* (1701), *The Grounds of Criticism in Poetry* (1704), and *An Essay on the Genius and Writings of Shakespear* (1712). His basic contention was that literature, and especially drama, is comparable to religion in that its effect is to move men's minds by means of the emotions. What Dennis looked for primarily in a work of art was passion and elevation rather than decorum and polish. His idol among English poets was John Milton. This bias may explain Dennis' antipathy toward Pope and probably accounts for the hostility between them. Pope, who thought Dennis' work bombastic, included an adverse allusion to Dennis in his "Essay on Criticism." Dennis replied with *Reflections Critical and Satirical* (1711), which mixed criticism of Pope's poem with a vicious personal attack upon Pope as "a hunch-back'd toad" whose deformed body mirrored a deformed mind. Despite a temporary reconciliation, the quarrel continued sporadically until Dennis' death. Dennis also defended the drama against the English bishop Jeremy Collier's condemnation of it in 1698. Dennis argued that plays discouraged disaffection by spreading pleasure and providing exercise for the passions.

Dennis, Nigel, in full NIGEL FORBES DENNIS (b. Jan. 16, 1912, Bletchingley, Surrey, Eng.—d. July 19, 1989, London), English writer and critic who used absurd plots and witty repartee to satirize psychiatry, religion, and social behaviour, most notably in his novel *Cards of Identity* (1955). It depicted the ease with which a group of tricksters could compel people to assume false identities because their real ones were so nebulous.

Dennis spent his early childhood in Rhodesia (now Zimbabwe) and was educated, in part, at the Odenwald School in Germany. He went to the United States in 1934, working for the National Board of Review of Motion Pictures in New York City (1935–36) and then as associate editor and book reviewer for *The New Republic*. He was employed as a staff book reviewer at *Time* magazine (1940–58). He was dramatic critic for *Encounter* magazine (1960–63) and returned as joint editor (1967–70). His book reviews also appeared regularly in the *Sunday Telegraph*.

In his first novel, *Boys and Girls Come Out to Play* (1949; U.S. title *A Sea Change*), Dennis explored the Adlerian notion that each individual's personality adapts to fit the social context. Both *Cards of Identity* and *A House in Order* (1966) retained some of his original concerns. *The Making of Moo*, a satirical play on

religion, was performed in 1957 and was published, together with the stage version of *Cards of Identity*, as *Two Plays and a Preface* (1958). His knowledge of journalism sharpened the satire of *August for the People* (1961), a much-praised play about the power of the press.

Dennison, Aaron Lufkin (b. March 6, 1812, Freeport, District of Maine, Massachusetts, U.S.—d. Jan. 9, 1895, Birmingham, Warwickshire, Eng.), watch manufacturer who was among the first to adapt the concept of interchangeable parts to the production of pocket watches. He is generally credited with being the father of American watchmaking.

Apprenticed at the age of 18 to a watchmaker in Brunswick, Maine, he learned the prevailing manual methods of watchmaking. Later he went to Boston, set up his own business, and then studied the mass-production techniques being employed in making firearms at the Springfield arsenal. Surmounting the technical difficulties of machine production of small parts, Dennison in 1850 set up a factory and began to supply the market with the first inexpensive factory-made watches. His shop, forced into bankruptcy in the financial panic of 1857, was reorganized by new backers in 1859, becoming the American Waltham Watch Company. Dennison's introduction of machinery into the manufacture of paper boxes and other paper products resulted in the founding of the Dennison Manufacturing Company.

Denon, Dominique Vivant, Baron (b. Jan. 4, 1747, Chalon-sur-Saône, Fr.—d. April 27, 1825, Paris), French artist, archaeologist, and museum official who played an important role in the development of the Louvre collection.

Denon studied law in Paris but turned to the theatre, writing a successful comedy at 23. He drew and painted and was commissioned by Louis XV to arrange a cabinet of carved gems. Between 1772 and 1787 he carried out diplomatic missions to Russia, Naples, and Switzerland; in Naples he etched portraits and collected works of art. In 1787 he became a member of the Académie de Peinture.

During the French Revolution he returned to Paris, where he was protected by his friend, the painter Jacques-Louis David. In 1798 he accompanied Napoleon Bonaparte on the latter's expedition to Egypt and there made numerous sketches of the ancient monuments, sometimes under the very fire of the enemy. The results were published in his *Voyage dans la basse et la haute Égypte* (1802; "Travels in Lower and Upper Egypt"). In 1804 Napoleon made Denon director general of museums, a post he retained until 1815. In this capacity he accompanied the Emperor on his expeditions to Austria, Spain, and Poland and advised him in his choice of works of art to pillage from the various conquered countries. Most of these works ultimately reached the Louvre.

After Denon had become acquainted with the work of Aloys Senefelder, the inventor of lithography, he was one of the first artists to introduce lithography into France. His first extant lithograph is dated September 1809. His unfinished but admirably illustrated history of art was published posthumously in four volumes in 1829 under the title *Monuments des arts du dessin chez les peuples tant anciens que modernes* ("Monuments of the Arts of Design Among Peoples As Much Ancient As Modern").

Denpasar, city, capital of Bali *propinsi* (province), south central Bali, Indonesia, 40 miles (70 km) south of Singaraja. The largest city on the island of Bali, it is also the capital of the Badung *kabupaten* (regency). Denpasar was the site of a suicidal battle of the rajas of Badung against the Dutch Militia in 1906.

A large open square in the centre of the city, named Puputan Square, commemorates the event. The population is mostly Balinese who speak a dialect of Indonesian written in Pallava script and practice a form of Islam strongly influenced by Hindu customs. In addition, there are Arab and Indian merchants who deal mainly in textiles; Chinese operate most local businesses, and there are some Christians. The city's mechanized industries include food processing, papermaking and printing, and the manufacture and repair of machinery. Handicrafts include sandstone carving, weaving, coconut and bone carving, plaiting, basket weaving, and the production of coin and of gold and silver jewelry.

A network of roads links Denpasar with Singaraja and other cities on the island. Denpasar also has an international airport. A branch of the National Archaeological Research Centre; the Bali Museum, built by the Dutch government in 1932 and containing specimens of Balinese art from prehistoric times to the early 20th century; and Universitas Udayana (founded 1962) are located at Denpasar. Sites of interest include the Puri (temple) Pemecutan, St. Joseph Church, Meredith Memorial Library, Pasar (market) Dadung, Kekar (Conservatory of Performing Arts), Academy of Indonesian Dances, and Abiankohas Art Centre. Pop. (1990) 345,200.

densitometer, device that measures the density, or the degree of darkening, of a photographic film or plate by recording photometrically its transparency (fraction of incident light transmitted). In visual methods, two beams of equal intensity are used. One is directed through the plate, while the intensity of the other is adjusted by an optical wedge, by an iris diaphragm, or by moving the source, until the two beams have equal intensity, judged by the eye or by a photoelectric cell. With proper calibration, the density can be read directly. Other methods employ photoelectric cells to measure the intensity of the same beam with and without film or plate inserted in the path, the difference in intensity being a measure of density.

The same techniques can be used to measure the density of semitransparent materials other than photographic plates—for example, sunglasses.

density, mass of a unit volume of a material substance, expressed as kilograms per cubic metre in MKS or SI units; the densities of common solids, liquids, and gases are listed in textbooks and handbooks. Density offers a convenient means of obtaining the mass of a body from its volume or vice versa; the mass is equal to the volume multiplied by the density, while the volume is equal to the mass divided by the density. The weight of a body, which is usually of more practical interest than its mass, can be obtained by multiplying the mass by the acceleration of gravity. Tables that list the weight per unit volume of substances are also available; this quantity has various titles, such as weight density, specific weight, or unit weight. *See also* specific gravity. The expression particle density refers to the number of particles per unit volume, not to the density of a single particle.

density current, any current in either a liquid or a gas that is kept in motion by the force of gravity acting on small differences in density. A density difference can exist between two fluids or between different parts of the same fluid because of a difference in temperature, salinity, or concentration of suspended sediment.

Density currents in nature are exemplified by those currents that flow along the bottom of oceans or lakes. Such subaqueous currents occur because the water entering an ocean or a lake is colder, saltier, or contains more suspended sediment and, thus, is denser than the

surrounding waters. As a consequence, it sinks and flows along the bottom under the effect of gravity. The difference in density, moreover, slows down the mixing of the subaqueous current with the overlying waters, enabling it to maintain itself for a relatively long distance.

Density currents are of considerable practical importance. For example, the deposition of sediment from turbidity currents—*i.e.*, density currents in which the density difference is caused by suspended sediment—in lakes may result in a rapid decrease of reservoir capacity. Equally significant, the industrial discharge of large amounts of polluted or heated water may generate density currents that have adverse effects on neighbouring human or animal communities.

Because of such considerations, many experimental studies on the properties of density currents have been undertaken. Small turbidity currents have been investigated in the laboratory and have been observed directly in lakes. Indirect evidence strongly suggests that large-scale turbidity currents occur in ocean basins. Many researchers believe that a current of this type is caused by the slumping of sediments that have accumulated at the head of a submarine canyon. Slumping of large masses of sediment produces a very dense sediment-water mixture that eventually flows down the canyon to spread out across the seafloor and deposit a layer of sand in the deep water. Repeated deposition results in the formation of submarine fans, structures that closely resemble the alluvial fans that occur at the mouth of many river canyons. Sedimentary rocks that are thought to have originated from ancient turbidity currents are called turbidites and are common in the geological record.

Densmore, Frances (b. May 21, 1867, Red Wing, Minn., U.S.—d. June 5, 1957, Red Wing), ethnologist, foremost American authority of her time on the songs and music of American Indian tribes, and widely published author on Indian culture and life-styles.

After studying at the Oberlin Conservatory of Music, Densmore conducted research in Indian music for the Bureau of American Ethnology in 1907. She subsequently worked with both the Bureau and the Smithsonian Institution and conducted a survey of Gulf Coast Indians for the National Research Council. In her published work she provided a new conception of the Indian, giving detailed analyses of the music and the circumstances under which songs were created and sung. She received the 1940–41 award of the National Association for American Composers and Conductors for her contributions to American musicology and conducted studies for a number of American museums and other organizations, including the Library of Congress. In 1941–43 she was consultant to the National Archives and established the Smithsonian–Densmore Collection of sound recordings of American Indian music.

Densusianu, Ovid (b. Dec. 29, 1873, Făgăraș, Rom.—d. June 9, 1938, Bucharest), folklorist, philologist, and poet who introduced trends of European modernism into Romanian literature.

Educated at Iași and later in Berlin and Paris, Densusianu was appointed professor of Romance languages at the University of Bucharest. Strongly influenced by western European Symbolism, he opposed the bucolic school of writing then established in Romania and in 1905 founded the opposition review *Viața Nouă* ("New Times"), which he published for 20 years. In French he wrote *Histoire de la langue roumaine* (1901–14; "A History of the Romanian Language"); in Romanian, *Dicționar general al limbii Române* (1909; "A General Dictionary of the Romanian Tongue"), *Flori alese din cântecele poporului* (1920; "An Anthology of the Songs of the People"), the poems *Raze pe lespezi*

(1920; "Sunlight on the Paving Stones"), and *Literatura română modernă* (1920–33; "Modern Romanian Literature"). His poetry is published under the pseudonym Ervin.

Dent, Edward John (b. Aug. 19, 1790, London—d. March 8, 1853, London), English clockmaker noted for his highly accurate clocks and chronometers.

Dent learned the clockmaker's trade from Richard Rippon and, during the period 1815–29, established a reputation as a builder of accurate chronometers. His reputation for precision eventually brought requests from the Admiralty and the East India Company. Dent confirmed his expertise by creating in 1829 a chronometer action that incorporated an improved method of reducing the timing errors caused by fluctuations in temperature. From 1830 until 1840 he was the partner of John Roger Arnold in the manufacture of first-rate clocks and watches. Thereafter, as the proprietor of three clock shops in London, Dent won the esteem of Sir George Airy, the astronomer royal, who recommended him as the maker of a large clock for the tower of the new Royal Exchange. Dent established a workshop in the Savoy to produce this excellent timepiece, which was installed in 1844.

In 1852 Dent won the commission to make the great clock—now called Big Ben—for the Houses of Parliament at Westminster, but he died before completing the project. Upon the death of Rippon, Dent had married his widow, whose sons Frederick and Richard took Dent's name and succeeded to his business. Frederick Rippon Dent finished Big Ben in 1854.

dental auxiliary, person qualified by training and experience to perform dental work under the direction and supervision of a dentist. Some of these auxiliary persons work directly for the dentist in his own office; others work in a separate office or laboratory, where they perform services to the dentist on the basis of work authorizations or prescriptions. There are three principal dental-auxiliary groups: dental hygienists, dental laboratory technicians, and dental assistants.

Dental hygienist. The hygienist, working under the direction of a licensed dentist, cleans and polishes the patient's teeth and gives advice on the care of teeth. Hygienists may also take and develop X-ray pictures of the teeth, mix filling compounds, apply fluorides to the teeth, and otherwise assist the dentist with a patient. In the United States, hygienists are also employed by public school systems to visit schools periodically, where they examine the teeth of the children and refer to a dentist cases in which treatment is indicated. Hygienists employed in hospitals may be called upon to work with bed and ambulatory patients who require limited prophylactic treatment.

Dental laboratory technician. A dental laboratory technician, upon receiving a prescription or work-authorization form from a licensed dentist, fabricates various appliances, such as full and partial dentures, crowns and bridges, and other prosthetic devices that the dentist uses in making restorations for the patient. The technician is not permitted to fit these appliances, nor may he take the impressions from which the dentures and other devices are fabricated.

Dental assistant. About 65 percent of all dental auxiliaries are dental assistants. Their duties vary according to the degree to which the dentist elects to delegate duties that do not require extensive professional knowledge. In general, the assistant is expected to prepare patients for dental treatment; to prepare materials and equipment for use by the dentist, including sterilizing and laying out instruments; to know instrument and equipment nomenclature; and to keep records of appointments, examinations, treatments, and supplies. A growing number of assistants are being trained to assist the dentist at the chair

in restorative dentistry, in surgical operations, and in prosthetic dentistry; many also are being trained to perform dental X-ray work.

Dentatus, Manius Curius (d. 270 BC), Roman general, conqueror of the Samnites and victor against Pyrrhus, king of Epirus.

Dentatus was born into a plebeian family that was possibly Sabine in origin. As consul in 290 BC, he gained a decisive victory over the Samnites, thereby ending a war that had lasted 50 years. The same year, he also reduced the Sabine insurgents to submission and granted them *civitas sine suffragio* ("citizenship without the right to vote"). In 284 he defeated the invading Senones. After Pyrrhus had returned from Sicily to Italy (275), Dentatus, once again consul, finally defeated him near Beneventum (now Benevento). Dentatus was consul for the fourth and last time in 274, the year he conquered the Lucanians. During his term as censor, 272, he began to build an aqueduct to carry the waters of the Anio River into the city but died before its completion. Later writers idealized Dentatus as a model of old Roman simplicity and frugality.

denticle, part of a conodont, a small toothlike fossil found in marine rocks representative of a long span of geologic time. Although they resemble cusps, denticles are generally smaller than distinct cusps and vary greatly in shape and structure. Denticles may be spaced closely to each other or separated by gaps of varying size; they may be distinctly formed or partially fused to each other. In shape, denticles may be needlelike, spiny, or saw-toothed. In some conodonts, denticles are completely absent, and the major part of the conodont consists of a single cusp. The form, number, and arrangement of denticles are frequently distinctive and characteristic of particular kinds of conodonts. In some forms, denticles are present as single straight, or almost straight, rows. In others, the denticles may be curved or even split into several branches. The earlier conodont forms that possess denticles generally consist of a main bar that supports the denticle row and the main cusp. In later forms, the main cusp and denticle row are flanked by a platform on either side.

dentine, also spelled DENTIN, in anatomy, the yellowish tissue that makes up the bulk of all teeth. It is harder than bone but softer than enamel and consists mainly of apatite crystals of calcium and phosphate. In humans, other mammals, and the elasmobranch fishes (e.g., sharks, rays), a layer of dentine-producing cells, odontoblasts, line the pulp cavity of the tooth (or, in the case of sharks, the toothlike scale) and send projections into the calcified material of the dentine; these projections are enclosed in tubules. Sensitivity to pain, pressure, and temperature is transmitted via the odontoblastic extensions in the tubules to and from the nerve in the pulp chamber. Secondary dentine, a less well-organized form of tubular dentine, is produced throughout life as a patching material where cavities have begun, where the overlying enamel has been worn away, and within the pulp chamber as part of the aging process.

In nonmammalian vertebrates, enamel is lacking; the tooth crown is covered instead with vitrodentine, a compound related to dentine, which is harder than dentine but somewhat softer than enamel.

A few animals, such as flounder and cod, have vasodentine, in which tubules are lacking, and the dentine is nourished directly by capillaries. Though more efficient nutritionally, this type of dentine is softer and less resistant to disease than tubular dentine. The material composing the toothlike scales of sharks and related fish is also called dentine. *Compare* cementum; enamel.

dentistry, profession concerned with the teeth and their associated structures such as the

jaws and gums. It includes the repair or removal of decayed teeth, the straightening of and adjusting for proper occlusion of teeth, and the design, manufacture, and provision of false teeth and other prosthetic devices.

A brief treatment of dentistry follows. For full treatment, see MACROPAEDIA: Medicine.

Origins of the treatment of oral disease are found in the ancient civilizations of the Middle and Far East. Until the 18th century dentistry was concerned only with the removal of teeth, and then only because of pain. Originally teeth were pulled by barber-surgeons, but by the 14th century there existed specialist tooth-pullers called dentatores, especially in France, where dentistry was more advanced than elsewhere in the world. In the 19th century the lead was taken by the United States, where most of the specialized equipment for dentistry was developed.

Early dental drills were hand-operated—the dentist twisting the bur between his fingers or turning a handle with one hand while drilling with the other. Later, a treadle-operated model was derived from the sewing machine, and in 1870 the electric drill was invented, though it was some while before the supply of domestic electricity brought it into universal use. It remained until ousted by the air turbine (high-speed) drill, developed in the 1950s. This has speeds around 400,000 rpm, allowing easier tooth repair with less discomfort.

Anesthesia and analgesia were introduced at the end of the 19th century, first by using cocaine or nitrous oxide and later other drugs. Another improvement in the practice of dentistry was the development of X rays, which revealed the condition of the roots of the teeth and any associated decay or infections.

False teeth were fairly common by the 18th century, but they were generally unsatisfactory; the impression of the jaw was made using plaster, which had to be chipped off painfully and pieced together again. The resulting denture was made from wood, ivory, or tortoiseshell, with teeth of ivory or porcelain, but was usually a poor fit and therefore uncomfortable. Improvements came first with the development of wax and then plastics for impression taking and, later, with the introduction of rubber and then plastic as the base on which the false teeth could be set. Also, early dentures had prongs or wires to attach them to the jaws, but they nevertheless were wobbly; almost all modern dentures use the capillary action of water to hold them in place, and this requires that they have a precise fit. The technique of permanently implanting false teeth in the gums became popular in the second half of the 20th century.

The other major developments in dentistry have been (1) oral hygiene and brushing for the prevention of tooth decay and gum disease, (2) the use of fluorides to make teeth resistant to decay, and (3) the development of orthodontics (tooth straightening.)

The first dental school was founded in Baltimore in 1840. Now most countries of the world require dentists to undergo a formal training lasting five to six years, after which they must pass written and practical examinations. Dentistry also requires a high degree of mechanical dexterity because the practice involves using highly sophisticated instruments and materials.

The work of a dentist involves not only filling and extracting teeth but also scaling and polishing the teeth to remove tartar, advising on the care of the teeth and gums, designing and supplying false teeth, restoring damaged teeth, and straightening teeth.

Denton, city, seat (1857) of Denton County, northern Texas, U.S. Denton is situated about 35 miles (56 km) northwest of Dallas—

Fort Worth. Permanently settled in 1857 and named for John B. Denton, a Texas frontiersman and Indian fighter, the city, although in an industrial and agricultural region, is largely a cultural, research, and educational centre, with the University of North Texas (1890), Texas Woman's University (established as Girls Industrial College in 1901), and Denton State School (1960) for the mentally retarded. It is the site of the first federal regional emergency centre, headquarters for civil defense, disaster, and preparedness operations in a five-state area. Inc. 1866. Pop. (2000) 80,537.

D'Entrecasteaux Channel, inlet of the Tasman Sea, extending northeast for about 35 miles (55 km) between Bruny Island (east) and the southeast coast of mainland Tasmania, Australia, to merge with the Derwent River estuary. Sighted in 1642 by the Dutch navigator Abel Tasman, it was surveyed in 1792 by the French admiral Bruni d'Entrecasteaux, who proved it to be a channel rather than a bay. It is known locally as The Channel. Its western shoreline is interrupted by the large indentations of Port Esperance and the Huon River estuary. The channel is the southern approach to Hobart.

D'Entrecasteaux Islands, islands in Papua New Guinea, lying across Ward Hunt Strait from the eastern tip of New Guinea, in the Solomon Sea, southwestern Pacific Ocean.

The large islands of Normanby, Fergusson, and Goodenough (*qq.v.*) and the much smaller Sanaroa (Welle) and Dobu are volcanic, precipitous (rising to 5,000–8,000 feet [1,500–2,400 m]), and forested. Perhaps the remnants of a submerged mountain range, they have a combined land area of 1,213 square miles (3,142 square km). Visited and named by the French navigator Bruni d'Entrecasteaux during his search for Jean-François de Galaup La Pérouse in 1793, the group was more accurately charted and individually named by John Moresby of HMS *Basilisk* in 1873.

denture, artificial replacement for one or more missing teeth and adjacent gum tissues. A complete denture replaces all the teeth of the upper or lower jaw. Partial dentures are commonly used to replace a single tooth or two or more adjacent teeth. The partial appliance may be removable or fixed; it usually relies on remaining teeth for stability.

Improved stability is sometimes obtained with overdentures, appliances that use remaining teeth and roots for support. An added advantage of overdentures is that the remaining roots help preserve the alveolar bone—the part of the jawbone that holds the teeth—in turn preserving important bone, nerve, and tissue that tend to degenerate in the presence of complete, full-mouth dentures.

A two-step system involving the surgical implantation of titanium fixtures—titanium bonds to human bone—and the later attachment of replacement teeth has also been developed. This method was particularly successful with individuals unable to wear dentures because of resorption (shrinkage of the jawbone).

Denver, city and county, capital of Colorado, U.S., at the western edge of the Great Plains, just east of the Front Range of the Rocky Mountains. The city and county form a single administrative unit. Denver lies at the junction of Cherry Creek and the South Platte River; its elevation (5,280 feet [1,609 metres] above sea level) gives it the nickname "Mile High City." Denver has emerged as the centre of a string of urban areas that now stretches along the Rockies from Fort Collins in the north to Pueblo in the south. Inc. 1885. Area city, 155 square miles (401 square km). Pop. (2000) city, 554,636; Denver PMSA, 2,109,282; Denver-Boulder-Greeley CMSA, 2,581,506.

History. The site served as an early stopping place for Arapaho Indians, fur trappers, and traders. The discovery of gold in 1858 led to the founding of two towns on Cherry Creek, which grew during the 1859 Pikes Peak gold rush. In 1861, when Colorado Territory was established, the towns were consolidated into the city of Denver.

Fire devastated the city in 1863, and a year later a flash flood wreaked havoc. Uprisings by Cheyenne and Arapaho Indians on the plains in the 1860s resulted in their forced removal. Denver became the territorial capital in 1867. Railway connections, spearheaded by Denver's citizens, produced an economic boom that increased the population from 4,759 in 1870 to 106,713 in 1890. During the 1870s and '80s, silver eclipsed gold in importance. Mining fortunes were created almost overnight, and an opera house was built. This period of opulence ended in 1893 with the crash of the silver markets. New gold discoveries helped prevent a major decline, and farming, ranching, and tourism began to provide a more stable economy.

State Capitol, Denver, Colo.

David Muench

After World War II, defense contractors and other facilities related to the Cold War energized the economy, but most of these activities ended in the 1990s. Another boost came as oil production soared in the 1970s. But Denver's population soon began to decline, and a crash in oil prices in the mid-1980s led to economic bust. Prosperity returned in the 1990s.

The contemporary city. The present-day metropolitan area spreads well into the foothills to the west of the city and the high plains surrounding it on the other three sides. Latinos (particularly of Mexican descent) comprise one-third of Denver's population.

The region's rapid growth since 1950 has increased the strain on its infrastructure, especially water and transportation systems. Traffic congestion and pollution are chronic problems.

As the largest city between the Missouri River and the Pacific states, Denver is a transportation, industrial, and commercial hub. Major businesses include telecommunications, aviation and aerospace, software, financial services, and health care. Tourism is important as well. Manufactures include electronics, rubber products, pharmaceuticals, medical equipment, and packaging, and brewing in nearby Golden. A branch of the U.S. Mint (1906) produces about half of circulating U.S. coinage. Denver International Airport is about 23 miles (37 km) northwest of the city.

The city is the seat of the University of Denver (1864), Regis University (1877), Iliff School of Theology (1892), Metropolitan State College of Denver (1965), and a branch campus of the University of Colorado. The State Capitol (1887–95) has a 272-foot (83-metre) gold-leafed dome, and Civic Center Park adjoins the Capitol grounds. Denver's climate and geographical location make outdoor recreation an especially popular pastime. The Rocky Mountains provide opportunities for

skiing, hiking, rafting, and mountain biking. Bicycle paths are laid out across the city itself.

Denver has professional baseball, basketball, gridiron football, hockey, and association football (soccer) franchises. City attractions include the Black American West Museum and Heritage Center, the Colorado History Museum, and the Denver Art Museum. The Denver Zoo houses nearly 4,000 animals. The Denver Performing Arts Complex is the home of the state ballet, opera, and symphony orchestra. The annual National Western Stock Show includes a rodeo and livestock and horse shows.

Denver and Rio Grande Western Railroad Company, byname RIO GRANDE, American railroad chartered in 1870 as the Denver and Rio Grande Railway. It began with a narrow-gauge line extending from Denver south to New Mexico and west to Salt Lake City. The running time between Denver and Salt Lake City was shortened by eight hours with the opening of the 6-mile (10-kilometre) Moffatt Tunnel through the Rockies in 1934, placing Denver on a transcontinental route for the first time.

The railroad operates along more than 3,000 miles (4,800 km) of track between Missouri and Utah and is one of the few American lines to carry passengers. Much of its freight revenues are from bituminous coal and lignite. Other sources include food products, lumber, and motor vehicles. The railroad was absorbed by the Southern Pacific Rail Corp. in 1988.

Denys, SAINT: *see* Denis, Saint.

Deo Van Tri, LAO KHAM UM (b. c. 1849, northwestern Vietnam—d. March 1, 1908, Lai Chau), fiercely independent tribal chief of Tai peoples in the Black River region of Tonkin (now northern Vietnam) who created a semiautonomous feudal kingdom and coexisted with the French, who ruled the rest of Vietnam.

Deo Van Tri was the son of Deo Van Seng, chief of the Tais who occupied the Vietnamese lands surrounding the Black River. As the head of a band of Chinese pirates, Deo Van Seng had seized the area in 1869. Deo Van Tri at age 16 joined with his father to repel a Shan invasion, and, together with the Black Flag pirate bands, he defended the kingdom of Vietnam. For his bravery the Vietnamese court named Deo Van Tri chief and accorded his father a mandarin title.

In 1885, with Tonkin at war against France, Deo again served the Vietnamese loyally. He offered refuge to the young rebel king, Ham Nghi, and the regent, Ton That Thuyet. The regent, however, tried to assassinate Deo in order to ensure the secrecy of their whereabouts. Deo thenceforth refused to associate with the Vietnamese resistance effort.

Deo came to terms with France in 1888 to protect his people's independence, agreeing to serve the French colonial regime. He accompanied the French explorer Auguste Pavie on several journeys and on a mission to China. Continuing this policy of cooperation, Deo assisted in operations delimiting the Indochinese frontier with China in 1894.

Deoband school, Arabic DĀR AL-'ULŪM ("House of Learning"), the leading Muslim theological centre (madrasah) of India. It was founded in 1867 by Muhammad 'Abid Husayn in the Sahāranpur district of Uttar Pradesh. The theological position of Deoband has always been heavily influenced by the 18th-century Muslim reformer Shāh Walī Allāh and the early 19th-century Indian Wāhhābīyah, giving it a very puritanical and orthodox outlook.

The program of studies is highly traditional, stressing jurisprudence (*fiqh*), Qur'anic exegesis (*tafsīr*), the study of traditions (Hadīth), scholastic theology (kalam), and philosophy

(*falsafah*). Modern disciplines, which are not relevant to a proper knowledge of Islām and can lead to sinful innovation (*bid'ah*), are ignored, and the modern practice of Islām is studied only in order to purify it of unorthodox accretions. The student is thus prepared mainly for religious leadership of the Muslim community.

Deoband's enrollment of about 1,500 students is culled from all parts of the Muslim world. The madrasah boasts a library of 67,000 printed books and manuscripts in Arabic, Persian, and Urdu. A mosque, lecture halls, and student residences further serve the scholarly community.

Deoghār, also spelled DEOGARH, town, north-eastern Bihār state, northeastern India. It is a major rail and road junction and agricultural trade centre. An ancient town, it is famous for its group of 22 temples dedicated to the Hindu god Śiva (Shiva). Numerous Buddhist ruins are nearby. Deoghar has a hospital, tuberculosis clinic, and leper asylum and houses several colleges (including a teacher-training institute) affiliated with Bhāgalpur University. The Muslim invader Bakhtiyār Khalji made Deoghar his capital in 1201 after the conquest of Bihār. It was constituted a municipality in 1869. Pop. (1991) town, 76,322; metropolitan area, 85,846.

Deogir (India): see Daulatābād.

deontological ethics, in philosophy, ethical theories that place special emphasis on the relationship between duty and the morality of human actions. Deontology (Greek *deon*, "duty," and *logos*, "science") consequently focuses on logic and ethics. No attempt is made in such theories to explicate specific moral obligations.

In deontological ethics an action is considered morally good because of some characteristic of the action itself, not because the product of the action is good. Deontological ethics holds that at least some acts are morally obligatory regardless of their consequences for human welfare. Descriptive of such ethics are such expressions as "Duty for duty's sake," "Virtue is its own reward," and "Let justice be done though the heavens fall."

By contrast, teleological ethics holds that the basic standard of morality is precisely the value of what an action brings into being. Deontological theories have been termed formalistic because their central principle lies in the conformity of an action to some rule or law.

The first great philosopher to define deontological principles was Immanuel Kant, the 18th-century German founder of critical philosophy, whose ethics were much influenced by Christianity as well as by the Rationalism of the Enlightenment. Kant held that nothing is good without qualification except a good will, which is one that wills to act in accord with the moral law and out of respect for that law, rather than out of natural inclinations. He saw the moral law as a categorical imperative—*i.e.*, an unconditional command—and believed that its content could be established by human reason alone. Reason begins with the principle "Act only on that maxim whereby thou canst at the same time will that it should become a universal law." Kant's critics, however, have questioned his view that all duties can be derived from this purely formal principle and have argued that, in his preoccupation with rational consistency, he neglected the concrete content of moral obligation.

This objection was faced in the 20th century by the British philosopher W.D. Ross, who held that numerous "prima facie duties," rather than a single formal principle for deriving them, are themselves immediately self-evident. Ross distinguished these prima facie duties (such as promise keeping, reparation, gratitude, and justice) from actual duties, for

"any possible act has many sides to it which are relevant to its rightness or wrongness"; and these facets have to be weighed before "forming a judgment on the totality of its nature" as an actual obligation in the given circumstances.

Deor, also called DEOR'S LAMENT, Old English heroic poem of 42 lines, one of the two surviving Old English poems to have a refrain. (The other is the fragmentary "Wulf and Eadwacer.") It is the complaint of a *scop* (minstrel), Deor, who was replaced at his court by another minstrel and deprived of his lands and his lord's benevolence. In the poem Deor recalls, in irregular stanzas, five examples of the sufferings of various figures from Germanic legend. Each stanza ends with the refrain "That trouble passed; so can this." Though some scholars believe that the lament is merely a conventional pretext for introducing heroic legends, the mood of the poem remains intensely personal.

Deoria, town, eastern Uttar Pradesh state, northern India, about 32 miles (50 km) south-east of Gorakhpur. On a major rail line to Bihār state, it is an agricultural trade centre. Its principal industry is sugar milling. Major crops grown in the surrounding agricultural area include sugarcane, rice, oilseeds, and pulses; there are also a number of sugar-processing factories. Nearby Kasia (ancient Kuśinagara), the reputed place of Buddha's death and cremation, is a noted pilgrimage centre. Pop. (1991) town, 81,943.

Deosai Mountains, range in the Himalayan mountain system in the northern part of the Indian subcontinent. The mountains are located in the Pakistani-held sector of the west-central part of the state of Jammu and Kashmir. The range extends for 120 miles (190 km) from the Indus River bend at Bunji to the Suru (Karcha) River, which separates the range from the Zaskār Range. The main body of the Deosai massif (mountainous mass) is composed of sedimentary rock of the Precambrian Era (which occurred from 3.8 billion to 570 million years ago) combined with granite bodies of younger age. Several peaks reach elevations of more than 18,000 feet (5,500 m). The Deosai Basin lies between mountain ranges at an elevation of 13,000 feet (4,000 m); it possesses steep sides and a level floor and appears to be an ancient cirque (deep, steep-walled recess in a mountain, caused by glacial erosion). The terrain of the Deosai Mountains is rugged and almost devoid of human population. Sparse vegetation vies for existence with a few hardy alpine mammals such as the marmot. The Burji Pass is situated southwest of Skārdu, which is one of several villages lying at the foot of the mountains.

deoxyribonucleic acid: see DNA.

deoxyribose, also called D-2-DEOXYRIBOSE, five-carbon sugar component of DNA (*q.v.*; deoxyribonucleic acid), where it alternates with phosphate groups to form the "backbone" of the DNA polymer and binds to nitrogenous bases. The presence of deoxyribose instead of ribose is one difference between DNA and RNA (ribonucleic acid). Deoxyribose was synthesized in 1935, but it was not isolated from DNA until 1954.

Depardieu, Gérard (b. Dec. 27, 1948, Châteauroux, Fr.), French motion-picture actor noted for his versatility and for his unusual combination of gentleness and physicality.

The son of migrant labourers, Depardieu received little formal education and at age 15 went to Paris, where he studied acting. He made his screen debut in the short film *Le Beatnik et le minet* (1965) and began to appear as a bit player in full-length films in the early 1970s. His performance as a young thug in *Les Valseuses* (1973; *Going Places*) brought

him his first real notice, and he subsequently appeared in such major films as Bernardo Bertolucci's *1900* (1976), François Truffaut's *Le Dernier Métro* (1980); *The Last Metro*, *Loulou* (1980), *Le Retour de Martin Guerre* (1981); *The Return of Martin Guerre*, Andrzej Wajda's *Danton* (1982), *Jean de Florette* (1986), and its sequel, *Manon des Sources* (1986; *Manon of the Spring*). He starred in *Camille Claudel* (1989), and in 1990 he won the best actor award from the Cannes International Film Festival for his role in *Cyrano de Bergerac* (1990).

Depardieu played a wide variety of roles, including both historical figures (from peasants to the French Revolutionary leader Georges Danton and artist Auguste Rodin) and contemporary figures (from composers to thugs). He was notable for projecting a screen image of masculine strength that was nevertheless imbued with gentleness and sensitivity. He acted in as many as six films a year, and by the late 1980s he had become the most popular actor in France and had achieved an international reputation.

département, largest unit of local government in France and in some former French colonies. The *départements* were originally created in 1790. Each *département* is governed by an elected general council, which holds responsibility for local services, laws, and budget; an officer called a commissioner represents the national government and is the council's executive agent.

Prior to the French Revolution the local unit in France was the military *gouvernement*, which roughly corresponded to the old provinces, such as Franche Comté, Provence, Bourgogne, Bretagne, and so on. But by the time of the French Revolution this division seemed too closely bound up with the administrative mismanagement of the ancien régime, and, at the suggestion of the Count de Mirabeau, the "provinces" were divided into *départements*, which were roughly equal to a certain average of size and population and which derived their names principally from rivers, mountains, or other prominent geographic features. In 1860 three new *départements* were created out of the newly annexed territory of Savoy and Nice. The three *départements* of Bas-Rhin, Haut-Rhin, and Moselle, which were lost after the Franco-German War in 1871, were restored in 1919. Other *départements* have been created on occasion because of population or territorial changes. By the late 20th century the number of *départements* had grown to about 100. The largest city in a *département* usually serves as the departmental capital.

Each *département*, presided over by its commissioner, is subdivided into *arrondissements*, each of which is under the administration of a subprefect. *Arrondissements* are again subdivided into cantons and these into communes, which are somewhat equivalent to the English parish.

INDEX
first

department store, retail establishment that sells a wide variety of goods. These usually include women's and girls' ready-to-wear apparel and accessories, men's and boys' ready-to-wear apparel and accessories, yard goods and household textiles, small household wares, furniture, electrical appliances and accessories, and, often, food. These goods are separated into divisions and departments supervised by managers and buyers. There are also departmental divisions of merchandising,

advertising, service, accounting, and budgetary control.

The Bon Marché (*q.v.*) in Paris, which began as a small shop in the early 19th century, is often considered the first department store. The development of department stores was linked to the growth in the 19th century of large population centres, transportation, and the harnessing of electricity for power and lighting. During that century many general merchandise stores grew into department stores by broadening their stocks. In the United States in the 1920s some stores began opening branches in various cities. The first such chains were J.C. Penney and Sears, Roebuck.

depersonalization, in psychology, a state in which an individual feels that his self or the outside world is unreal. In addition to a sense of unreality, depersonalization may involve the feeling that one's mind is dissociated from one's body; that the body extremities have changed in relative size; that one sees oneself from a distance; or that one has become a machine.

Mild feelings of depersonalization occur during the normal processes of personality integration and individuation of a high percentage of adolescents and young adults and need not impair social or psychological functioning. Such feelings may also occur in adults after long periods of emotional stress. When significant social or occupational impairment continues, an individual is considered to have a disorder which should be treated. Feelings of depersonalization may also be present as secondary symptoms in disorders such as depression, hysteria, or schizophrenia.

According to Sigmund Freud's psychoanalytic theory, since ego is the "representative of reality," depersonalization is a result of impairment of ego functioning. Depersonalization is often interpreted as a defensive reaction to an unconscious need to escape from an intolerable or threatening reality.

The term *depersonalization* has also been used to refer to social alienation resulting from the loss of individuation in the workplace and the community.

Depew, Chauncey Mitchell (b. April 23, 1834, Peekskill, N.Y., U.S.—d. April 5, 1928, New York City), U.S. railroad lawyer and politician who is best remembered as an orator, a wit, and an after-dinner speaker.

Entering politics as a Republican, Depew served as a member of the New York Assembly (1861–62) and as secretary of state of New York (1864–65). In 1866 he declined an appointment as the first U.S. minister to Japan in order to become an attorney and lobbyist for Cornelius Vanderbilt's New York and Harlem Railroad. Eventually he rose to be president of the New York Central and Hudson River Railroad (1885–98) and board chairman of the entire Vanderbilt railway sys-

tem (from 1898). A candidate for the Republican nomination for president in 1888, he withdrew in favour of Benjamin Harrison, whose successful campaign he strongly supported. In 1892 he declined Harrison's offer of the secretaryship of state. He later served two terms (1899–1911) as a U.S. senator from New York.

depletion allowance, in corporate income tax, the deductions from gross income allowed investors in exhaustible mineral deposits (including oil or gas) for the depletion of the deposits. The theory behind the allowance is that an incentive is necessary to stimulate investment in this high-risk industry.

The depletion allowance is similar to the depreciation (*q.v.*) allowance afforded other firms for their investments. There are substantial differences, however. One is that it is difficult to estimate what proportion of a mineral deposit has been exhausted. Another is that the value of the deposit is often substantially larger than the amount invested. The search for a deposit entails considerable risk, but once it is found, it may justify high levels of investment even without tax incentives.

The first depletion allowance in the United States, called the "discovery depletion," was enacted in 1918 to stimulate oil production for World War I (even though the war had just ended). Discovery value proved too hard to estimate, however, so this was changed in 1926 to the "percentage depletion" for oil and gas property, under which the corporation deducts a fixed percentage of its sales as a depletion allowance, regardless of the amount invested. In addition, producers can deduct their capital costs, thus gaining a double benefit. After 1931, Congress expanded the use of "percentage depletion" to many other extractive industries, such as those concerned with metals, sulfur, and coal.

Proponents of the depletion allowance claim that special treatment for the oil and gas industry is justified because of the high risks involved and because reliable oil supplies are vital to national defense. Opponents argue that overly beneficial depletion allowances lead to over-investment in the favoured industries and excessive exploitation of some minerals while distorting allocation of resources. After years of debate, the depletion allowance for oil and gas was reduced from 27.5 percent to 22 percent in 1969 and completely eliminated for certain large producers in 1975. Only small, independent companies and royalty owners, as well as owners of geopressurized methane gas wells, were allowed a percentage depletion, but it was to decline gradually to 15 percent beginning in 1984.

deportation, expulsion by executive agency of an alien whose presence in a country is deemed unlawful or detrimental. Deportation has often had a broader meaning, including exile, banishment, and the transportation of criminals to penal settlements.

In Roman law, deportation originally described a form of banishment for life to a foreign country, usually an island. Deportation was at first inflicted upon political criminals, but, in time, it became a means of removing those whose wealth and popularity rendered them objects of suspicion. It was also a punishment for adultery, murder, poisoning, forgery, embezzlement, and other crimes. Deportation was attended by the confiscation of property, loss of citizenship, and loss of civil rights. The practice of transporting criminals to foreign soil began in Europe in the 15th century, when Portugal sent convicts to South America, where they became some of the earliest settlers of Brazil. France initiated deportation during the Revolutionary period; the practice survived until 1938 despite much public criticism of the prison conditions on the islands of French Guiana, particularly the notorious Devil's Island. Peter I the Great of

Russia ordered political prisoners to Siberia in 1710, thus beginning a practice that has continued through the 20th century.

In England deportation developed from the policy of allowing an arrested man the option to abjure the realm. He would take an oath to depart and never return. Often this represented the convict's only alternative to execution. Gradually a formal system of transportation of convicted criminals developed as a substitute for capital punishment. The inhuman treatment of criminals sentenced to servitude in the colonies of North America and Australia generated public pressure for penal reform, and the practice was abandoned in the 1850s.

In Anglo-American law today, deportation is a civil enactment imposed on persons who are neither native-born nor naturalized citizens. The alien is ordinarily, but not necessarily, returned to the country from which he came, usually because he has entered the deporting country illegally or without proper passport or visa. Aliens who become public charges, commit crimes involving moral turpitude, or engage in subversive activities can also be subjected to deportation proceedings. U.S. courts have shown leniency in circumstances in which families are split apart unjustifiably and left with no means of support.

Deportation differs from exclusion, extradition, and exile. Exclusion is the refusal by a governing authority to admit an alien. Extradition is the removal of a criminal to the country from which he has fled to avoid criminal prosecution or prison. Exile is a prolonged absence from one's country, either voluntary or by direction of the sovereign. *See also* exile and banishment; penal colony.

deposit, certificate of (CD), a receipt from a bank acknowledging the deposit of a sum of money. Among the common types are demand certificates of deposit and time certificates of deposit. Demand certificates of deposit are payable on demand, without drawing interest. They are used primarily by contractors as evidence of good faith when submitting a bid or as a guaranty of performance. They may also be used as collateral to secure a loan. Time certificates of deposit bear interest and are payable on or after a specific date. Interest on time deposits is higher than for passbook or statement savings accounts. A depositor who withdraws money deposited on a time basis before the maturity date of the certificate is subject to loss of interest. Since their introduction in the early 1960s, they have become a significant method of saving. Both types of certificates of deposit are usually negotiable, but checks may not be written against them.

Treasury rate certificates of deposit, recently allowed by the United States government, pay interest according to the discount rate for U.S. Treasury bills at the time that the certificate of deposit is purchased, and the interest rate is guaranteed for the life of the certificate. Sterling certificates of deposit were first issued in 1968 and are subject to the controls of the Bank of England.

In the United States, some certificates are negotiable and are acceptable as security for loans. The United States government sets a ceiling on the interest that may be offered on interest-bearing certificates of deposit.

depreciation, accounting charge for the decline in value of an asset spread over its economic life. Depreciation covers deterioration from use, age, and exposure to the elements. It also includes obsolescence—*i.e.*, loss of usefulness arising from the availability of newer and more efficient types of goods serving the same purpose. It does not cover losses from sudden and unexpected destruction resulting from fire, accident, or disaster.

Depew, detail of an oil painting by Vilma Parlachy; in Yale University Art Gallery

Yale University Art Gallery gift of Mrs. Charles Carroll Glover, Jr.

Depreciation applies both to tangible property such as machinery and buildings and to intangibles of limited life such as leaseholds and copyrights. For convenience, depreciation accounts are usually kept for groups of assets with similar characteristics and working life.

The general rule of charging off a depreciable asset during its life does not determine what the charge will be each year. Straight-line, fixed-percentage, and, more rarely, annuity methods of depreciation (giving, respectively, constant, gradually decreasing, and gradually increasing charges) are standard. Sometimes charges vary with use (e.g., with the number of miles per year a truck is driven). Special rules allow depletion of nonreproducible capital (such as a body of ore being mined) for tax purposes to exceed original cost.

Basing depreciation on historical cost rather than on probable replacement cost and on arbitrary rules rather than on actual use has been practiced to establish definite tax liability and to standardize audits of accounts; in times of shifting price levels, however, such bases for measuring depreciation have proved especially imperfect.

depressant, in medicine, a drug or other agent that slows the activity of vital organs of the body. Depressants acting on the central nervous system include general anesthetics, opiates, alcohol, and hypnotics. Tranquilizing drugs (ataractics) act primarily on the lower levels of the brain, relieving tension without reducing mental sharpness.

depression, in economics, major downswing in the business cycle (*q.v.*) that is characterized by sharply reduced industrial production, widespread unemployment, serious declines or cessations of growth in construction activity, and great reductions in international trade and capital movements. Unlike minor business contractions that may occur in one country independently of business cycles in other countries, severe depressions have usually been nearly worldwide in scope. The Great Depression (*q.v.*) beginning in 1929, for example, was the most severe and widespread economic decline in the 20th century. *Compare* recession; panic.

depression, in psychology, a mood or emotional state that is marked by sadness, inactivity, and a reduced ability to enjoy life. A person who is depressed usually experiences one or more of the following symptoms: feelings of sadness, hopelessness, or pessimism; lowered self-esteem and heightened self-depreciation; a decrease or loss of ability to enjoy daily life; reduced energy and vitality; slowness of thought or action; loss of appetite; and disturbed sleep or insomnia. Depression differs from simple grief, bereavement, or mourning, which are appropriate emotional responses to the loss of loved persons or objects. Where there are clear grounds for a person's unhappiness, depression is considered to be present if the depressed mood is disproportionately long or severe vis-à-vis the precipitating event. When a person experiences alternating states of depression and mania (extreme elation of mood), he is said to suffer from a manic-depressive psychosis (*q.v.*).

Depression is probably the most common psychiatric complaint and has been described by physicians from at least the time of Hippocrates, who called it melancholia. The course of the disorder is extremely variable from person to person; it may be fleeting or permanent, mild or severe, acute or chronic. Depression is more common in women than in men. The rates of incidence of the disorder increase with age in men, while the peak for women is between the ages of 35 and 45.

Depression can have many causes. The loss of one's parents or other childhood traumas and privations can increase a person's vulnerability to depression later in life. Stressful

life events in general are potent precipitating causes of the illness, but it seems that both psychosocial and biochemical mechanisms can be important causes. The chief biochemical cause seems to be the defective regulation of the release of one or more naturally occurring monoamines in the brain, particularly norepinephrine and serotonin. Reduced quantities or reduced activity of these chemicals in the brain is thought to cause the depressed mood in some sufferers.

There are three main treatments for depression. The two most important are psychotherapy and drug therapy. Psychotherapy aims to resolve any underlying psychic conflicts that may be causing the depressed state, while also giving emotional support to the patient. Antidepressant drugs, by contrast, directly affect the chemistry of the brain, and presumably achieve their therapeutic effects by correcting the chemical imbalance that is causing the depression. The tricyclic antidepressant drugs are thought to work by inhibiting the body's physiological inactivation of the monoamine neurotransmitters. This results in the buildup or accumulation of these neurotransmitters in the brain and allows them to remain in contact with nerve cell receptors there longer, thus helping to elevate the patient's mood. By contrast, the antidepressant drugs known as monoamine oxidase inhibitors interfere with the activity of monoamine oxidase, an enzyme that is known to be involved in the breakdown of norepinephrine and serotonin. In cases of severe depression in which therapeutic results are needed quickly, electroconvulsive therapy has proven helpful. In this procedure, a convulsion is produced by passing an electric current through the person's brain. In many cases of treatment, the best therapeutic results are obtained by using a combination of psychotherapy with drug therapy or with electroshock treatment.

Depression, Great: *see* Great Depression.

Depretis, Agostino (b. Jan. 13, 1813, Mezzana Corti, Kingdom of Italy—d. July 29, 1887, Stradella, Italy), Italian statesman, a leftist figure in the Risorgimento who later served three times as premier of Italy. He provided a fairly stable government by the tactics of *trasformismo*, which brought together members of different parties in the same Cabinet.

After graduating from law school at Pavia (1834), he spent several years running his family's estate. In 1848, the year of revolutionary upheavals in Europe, he was elected deputy to the first Piedmontese Parliament, a position he held continuously until his death. As a deputy he consistently opposed Count Cavour, the premier of the kingdom of Piedmont-Sardinia.

Probably because he foresaw its failure, Depretis did not participate directly in the 1853 uprising in Milan planned by Giuseppe Mazzini, the extreme-left nationalist. After Cavour's resignation in 1859, Depretis briefly served as governor of Brescia in the province of Lombardy, which Piedmont had newly annexed from Austria.

Italy was politically unified in 1861, and Depretis became successively minister of public works (1862), minister of the navy (1866), and minister of finance (1867) in the weak national governments that followed unification. As nominal head of the leftists after Urbano Rattazzi's death in 1873, Depretis was invited to become premier in March 1876. For the next 11 years he was the dominant force in Italian politics. A scandal in March 1878 brought down his government before his moderately liberal reforms could be introduced. Returning to power in December 1878, he formed a more conservative government that lasted eight months.

In May 1881 Depretis organized a govern-

ment that lasted until July 1887, a period notable for its lack of change. The major reform achieved by his government was the extension of suffrage from 2 percent to 7 percent of the population (1882).

In 1882 Depretis signed the Triple Alliance, which allied Italy with Austria-Hungary and Germany. He was then persuaded to colonize Africa. When 500 Italian troops were killed by Ethiopians at the Battle of Dogali in January 1887, his government resigned. In April Depretis was again chosen as prime minister, but he died in office a few months later.

The diverse and unstable parties and factions in early Italian national politics made strict party government almost impossible. In response to this problem, Depretis perfected the art of *trasformismo* ("transformism"), by which, in order to build up his own personal following in parliament, he ignored party labels and took ministers from both the right and left. A prime minister could stay in office longer by means of the shifting government coalitions thus created. Cavour had done much the same thing as Italy's first prime minister, but under Depretis this practice became the established technique of Italian parliamentarism.

depth charge, also called DEPTH BOMB, a type of weapon that is used by surface ships or aircraft to attack submerged submarines. The first depth charges were developed by the British in World War I for use against German submarines. They consisted of a canister filled with explosives that was rolled or dropped off the stern of a ship in the presumed vicinity of the submerged submarine. The canister would sink through the water, and its explosive charge would be detonated at a preselected depth by means of a hydrostatic valve. The depth charge rarely exploded close enough to sink the submarine, but its shock waves loosened the submarine's joints and damaged its instruments, thus forcing it to the surface, where it could be finished off by naval gunfire. An attacking ship would try to drop a pattern of depth charges around a submarine to increase the chances of one exploding near enough to damage the sub.

Late in World War I, devices were developed to propel depth charges through the air over distances of 100 or more yards, thus widening the effective radius at which a ship could attack submarines. The Royal Navy's Hedgehog depth charge of World War II consisted of a salvo of 24 small, high-explosive bombs that could be launched to a distance of 250 yards (228 m) and which exploded on contact as they sank through the water. Other, more conventional depth charges weighing as much as 3,000 pounds (1,360 kg) were used in World War II. Modern depth-charge launchers are computer-controlled mortars that can fire 400-pound (180-kilogram) depth charges in patterns 2,000 yards (1,800 m) away from a ship. Atomic depth charges are fitted with a nuclear warhead and have a vastly increased killing radius owing to their great explosive power. Other depth charges have been developed that can be launched from aircraft.

depth finder, also called ECHO SOUNDER, device used on ships to determine the depth of water by measuring the time it takes a sound (sonic pulse) produced just below the water surface to return, or echo, from the bottom of the body of water. Sonic depth finders are in operation on practically every important class of ship, naval and merchant, and are also used on small craft.

Sonic pulses are also sent out to detect underwater objects by the same principle. During World War II the name sonar (*q.v.*) was applied in an analogy to radar, and the device was used extensively to detect submarines. In

addition to protecting ships from shoal water, peacetime uses include locating fish, measuring the thickness of ice in Arctic regions, and oceanographic charting. Sonic depth finders can be operated repetitively, recording thousands of soundings per hour, to prepare a profile of the ocean floor. Hydrographers use echo sounders in charting the oceans and in survey work to discover underwater pinnacles and shoals.

One of the first practical depth sounders, the so-called Hayes sonic depth finder, developed by the U.S. Navy in 1919, consisted of (1) a device to generate and send sound waves to the ocean floor and receive the reflected waves and (2) a timer calibrated at the speed of sound in seawater that directly indicated water depth. About 1927 a similar device was manufactured under the trade name Fathometer. The basic principles used in these early devices have not been significantly changed.

In the modern system a transmitter supplies a powerful pulse of electrical energy, and a transducer converts the pulse into an acoustical pressure wave in the water and receives its echo, converting it back into electrical energy, which can be amplified and applied to an indicator. Audible frequencies of less than 15 kilohertz are commonly employed.

Der'a (Syria): see *Da'ra*.

Dera Ghāzi Khān, town, Punjab province, central Pakistan. The town was founded by Ghāzi Khān, son of a Baluchi chieftain and vassal of the Langāh sultans of Multān. Incorporated as a municipality in 1867, the town was partially destroyed by a flood of the Indus River in 1908–09. The new town (founded 1911) is connected by road with Multān over the Taunsa Barrage and by a bridge of boats at low water over the Indus with Ghāzi Ghāt and Muzaffargarh. Rug and carpet weaving and the production of wooden toys were traditional industries; newer industries include rice and flour milling, cotton textiles, and rope and fibre products. The town has a hospital and a college affiliated with the University of the Punjab. Wheat, millet, and dates are the chief crops grown in the surrounding area, and cattle breeding is widespread. Pop. (1998) 188,149.

Dera Ismā'il Khān, town, North-West Frontier Province, Pakistan. The town, just west of the Indus River, was named for Ismā'il Khān, son of the 15th-century Baluchi chief who founded the town. The old town, 4 miles (6 km) east, was washed away by the Indus River in 1823. The new town, laid out by Durrāni chiefs, was constituted a municipality in 1867. Dera Ismā'il Khān is an important transportation junction that is connected to Darya Khān (12 miles [19 km] east) by a bridge spanning the Indus. Lacquered woodwork, glasswork, mat and ivory work, and lungis (sarongs) are the chief hand-manufactured goods; industry includes textile, flour, oil, and rice mills and soap factories. Wheat, millet, gram, and sorghum are the major crops cultivated in the surrounding area, and camels and sheep are extensively bred. The region is the junction of the Pashtun and Baluchi tribes. Dera Ismā'il Khān's facilities include a hospital, two parks, four main bazaars, and several colleges affiliated with the University of Peshāwar. Gomal University was opened in the town in 1974. Pop. (1998) 90,357.

Derain, André (b. June 10, 1880, Chatou, Fr.—d. Sept. 8, 1954, Garches), French painter who was one of the principal Fauvists.

Derain studied painting in Paris at the Académie Carrière and at the Académie Julian. He developed his early style in association with Maurice de Vlaminck, whom he met in 1900, and with Henri Matisse, with

whom he became acquainted in 1905. Together with these two painters, Derain was one of the principal exponents of Fauvism

"Self-Portrait," oil painting by André Derain; in the Bridgestone Gallery, Tokyo

By courtesy of the Bridgestone Art Gallery, Tokyo

(*q.v.*) in the period from 1905 to 1908. He painted landscapes and figure studies in brilliant, sometimes pure colours and used broken brushstrokes and impulsive lines to define his spontaneous compositions. Derain broke with Fauvism in 1908, when he temporarily came under the influence of the works of Paul Cézanne. He worked for a few years in a stylized form of Cubism, but by the 1920s his paintings of nudes, still lifes, and portraits had become increasingly Neoclassical, and the spontaneity and impulsiveness that had distinguished his earlier work gradually disappeared. His art underwent virtually no change after the 1920s. Derain had considerable ability as a decorator and created theatrical designs, notably for the Ballets Russes. He also produced numerous book illustrations.

derasha, also spelled **DERASHAH** (Hebrew: "discourse," or "homily"), plural **DERASHOT**, or **DERASHOTH**, in Judaism, a homily or sermon, generally preached by a rabbi in the synagogue.

In a broad sense, the prophets were the first to preach to the Jewish people, but they had no official status as interpreters of the Law, nor did they address their words to a formal congregation. The first *derashot*, properly so called, were preached by Ezra (5th century BC), who sensed the usefulness of following the reading of the Torah texts with a vernacular explanation for the common people. Long before the Christian era, such discourses became an integral part of the Jewish liturgy. In form and content, the *derashot* gradually changed with changing times. Some preachers provided didactic explanations of the Law, while others had recourse to allegory, parable, anecdote, or folklore.

Derashot were used by rabbis for the inspiration, encouragement, and sometimes the admonition of their congregations. Many early *derashot* from this era have been preserved in nonlegal sections of the Talmud and constitute a large portion of the Midrash (collected explanations of the underlying meaning of biblical texts). *Derashot* could serve as vehicles for social criticism and reform or as entertaining and instructive demonstrations of a rabbi's eloquence and learning. Ethical teachings, however, remained the basis of the *derasha*.

Modern *derashot* continue to be flexible in form and content, but their reliance on ancient sources and traditions gives them a distinctive Jewish flavour. A typical *derasha* remains a speech of exhortation and instruction based on a particular text from the Scriptures.

Derbent, city, Dagestan republic, southwestern Russia. The city lies in the narrow gap between the Caspian Sea and the Caucasus Mountains at their closest approach. Derbent was founded in AD 438 as a fortress to guard the principal caravan route from southwestern Europe to Southwest Asia. It fell to Arabs in 728, Tatars in 1220, and Russians in 1813. Many ancient monuments survive, including the ruins of the 5th-century citadel and an 8th-century cathedral mosque. The modern city's industries include wool spinning, wine making, and a large cannery. Pop. (2000 est.) 92,000.

Derby, town and port in West Kimberley shire, northern Western Australia. It lies on the western shore of a peninsula in King Sound (an inlet of the Indian Ocean), near the mouth of the Fitzroy River. Founded in 1883 to serve a pastoral district, it was named after Lord Derby, who was then the British secretary of state for the colonies. The town boomed during the Kimberley gold rush (1885) in the hinterland. Situated near the Great Northern Highway to Perth (1,500 miles [2,400 km] southwest), Derby is the major port for the cattle of West Kimberley. Beef cattle from the Fitzroy Valley and King Leopold Ranges are brought to slaughterhouses in Derby. The output of these and the nearby Glenroy Station works is shipped along the coast from a 1,800-foot (550-metre) jetty at Derby that was built to partially overcome difficulties presented by a 35-foot (11-metre) tidal range. Derby also serves the iron mines on Cockatoo and Koolan islands in Yampi Sound (80 miles [130 km] north). Pop. (1996) 3,236.

Derby, city and unitary authority, geographic and historic county of Derbyshire, England. It lies along the River Derwent at the southern end of the Pennines. The unitary authority covers Derby and its suburbs.

Just northeast of the city centre, at Little Chester, is the Roman site of Derventio. Derby was founded in the 9th century by the Danes as Deoraby, from which the present name is derived. Early royal charters were granted in 1154–56 and 1204. All Saints Church (cathedral from 1927) has a tower 210 feet (64 m) high that was built in 1509–27. The manufacture of porcelain in the locality began in 1750. After a visit by George III in 1773, the town was granted a patent to mark the china with a crown, and the local product was known thereafter as Crown Derby, amended to Royal Crown Derby by Queen Victoria in 1890. Silk throwing, or spinning by machine, was introduced into the town from Italy in 1719. Many people in Derby were formerly employed in the manufacture of silk hosiery, lace, and cotton, and textile factories are still important in the city's economy. Derby's early factories were helped by a canal network, and in the 19th century the city became a major railway centre. Rail and aircraft engineering are important industries in the city. Derby also has large cattle markets. Area 30 square miles (78 square km). Pop. (1998 est.) 235,800.

Derby, city, coextensive with the town (township) of Derby, New Haven county, southwestern Connecticut, U.S. It lies at the junction of the Housatonic and Naugatuck rivers, a few miles west of New Haven. Early settlement developed around a trading post established by Captain John Wakeman in 1642; colonists from Milford arrived in 1651. In 1675 it became a town and was renamed for Derby, Eng. Its boundary was reduced when Oxford (1798), Seymour (1850), and Ansonia (1889) were separately incorporated. The city of Derby was incorporated in 1893 and consolidated with the town. Derby prospered as a shipbuilding, shipping, and fishing centre, but these activities had declined by the mid-19th century. The economy is now based on diversified manufacturing. Pop. (2000) 12,391.

Derby, one of the classic English horse races, with the Saint Leger, the Oaks, the One Thousand Guineas, and the Two Thousand Guineas. It dates from 1780 and is named for Edward Stanley, 12th earl of Derby. With a field limited to three-year-old colts and fillies, the race is run the first Wednesday in June over a 1½-mile (about 2,400-metre) course at

The Derby at Epsom Downs

UPI—EB Inc

Epsom Downs, Surrey. Many other horse races have been named for the Derby (e.g., Kentucky Derby), and the term itself has come to signify a race or contest of any type. For winners of the Derby since 1949, see *Sporting Record: Horse racing*.

Derby, EARLS OF, titled English nobility of several creations, most notably in the family Stanley, grouped below chronologically and indicated by the symbol ●.

● **Derby, Henry, earl of:** see Henry IV under Henry (England).

● **Derby, Thomas Stanley, 1st earl of**, also called (1459–85) 2ND BARON STANLEY (b. c. 1435—d. July 29, 1504, Lathom, Lancashire, Eng.), a prominent figure in the later stage of England's Wars of the Roses.

Great-grandson of Sir John Stanley (d. c. 1414), who created the fortunes of the Stanley family, Thomas Stanley began his career as a squire to King Henry VI in 1454. At the Battle of Blore Heath in August 1459, Stanley, though close at hand with a large force, did not join the royal army, while his brother William fought openly for York. In 1461 Stanley was made chief justice of Cheshire by Edward IV, but 10 years later he sided with his brother-in-law Warwick in the Lancastrian restoration. Nevertheless, after Warwick's fall, Edward IV made Stanley steward of his household. About 1482 he married, as his second wife, Margaret Beaufort, mother of the exiled Henry Tudor (the future Henry VII).

Stanley was one of the executors of Edward IV and was at first loyal to the young king Edward V. However, he acquiesced in Richard III's accession and retained his office as steward, avoiding entanglement in the rebellion (1483) on behalf of Henry Tudor in which his wife was deeply involved. He was made constable of England and was granted possession of his wife's estates with a charge to keep her safe in some secret place at home. Richard III could not well afford to quarrel with so powerful a noble, but he became suspicious when, early in 1485, Stanley asked leave to retire to his estates in Lancashire, and in the summer Richard asked Stanley to send his son Lord Strange to court as a hostage. After Henry Tudor had landed, Stanley made excuses for not joining the King. On the morning of Bosworth (August 22), when Richard summoned Stanley to join him, he received an evasive reply and thereupon ordered Lord Strange to be ex-

ecuted, although his order was neglected and Strange escaped. After the Battle of Bosworth Field, Stanley, who had taken no part in the fighting, placed the crown on Henry's head. Henry VII confirmed him in all his offices and created him earl of Derby. His son Thomas succeeded him as 2nd earl of Derby.

● **Derby, Edward Stanley, 3rd earl of** (b. 1508/09—d. Oct. 24, 1572, Lathom House, near Ormskirk, Lancashire, Eng.), second son of the 2nd earl, succeeding to the earldom on his father's death in May 1521. During his minority Cardinal Wolsey was his guardian, and as soon as he came of age he began to take part in public life. He helped to quell the rising known as the Pilgrimage of Grace in 1536, but, remaining true to the Roman Catholic faith, he disliked and opposed the religious changes made under Edward VI. Under Elizabeth his younger sons, Sir Thomas (d. 1576) and Sir Edward Stanley (d. 1609), were concerned in a plot to free Mary, Queen of Scots, and he himself was suspected of disloyalty.

● **Derby, James Stanley, 7th earl of**, also called (until 1642) BARON STRANGE, byname GREAT EARL OF DERBY (b. Jan. 31, 1607, Knowsley, Lancashire, Eng.—d. Oct. 15, 1651, Bolton, Lancashire), prominent Royalist commander in the English Civil War, who was executed by the Parliamentarians.

Eldest son of William, the 6th earl, he was returned to Parliament for Liverpool in 1625 and on March 7, 1628, entered the House of Lords as Baron Strange. When the Civil War broke out in 1642, Lord Strange devoted himself to the cause of King Charles I, fighting chiefly in Lancashire. After several defeats he left for the Isle of Man in June 1643 to deal with the disturbances that had broken out there, and in the summer of 1644 he took part in Prince Rupert's successful campaign in the north. He followed Rupert to Marston Moor and, after the complete defeat of Charles's cause in the north, withdrew to the Isle of Man, where he held out for the King and offered an asylum to Royalist fugitives.

By the death of his father on Sept. 29, 1642, he had succeeded to the earldom, and on Jan. 12, 1650, was chosen by Charles II to command the forces of Cheshire and Lancashire in the proposed Royalist rising. On Aug. 15, 1651, he landed at Wyrce Water in Lancashire but on August 25 was totally defeated at Wigan, being severely wounded and escaping with difficulty. He joined Charles at Worcester; after the battle he accompanied him to Boscobel and, while on his way north alone, was captured near Nantwich, court-martialed at Chester on September 29, and condemned to death. When his appeal for pardon to Parliament was rejected, though supported by Oliver Cromwell, he endeavoured to escape but was recaptured and executed at Bolton. His eldest son, Charles (1628–72), succeeded him as 8th earl.

● **Derby, Edward (George Geoffrey Smith) Stanley, 14th earl of** (b. March 29, 1799, Knowsley Park, Lancashire, Eng.—d. Oct. 23, 1869, London), English statesman, important as leader of the Conservative Party during the long period 1846–68, thrice prime minister, and one of England's greatest parliamentary orators; nevertheless, he has no great political reputation.

Entering Parliament as a Whig in 1820, he held office under Viscount Goderich (1827–28) and became chief secretary for Ireland under Lord Grey in 1830, joining the Cabinet in 1831. In 1834 he resigned over the Irish Church question but served under Sir Robert Peel (1841), only to resign (1845) over the repeal of the Corn Laws. He succeeded to the earldom in 1851 and was premier in 1852, 1858, and 1866; among his legislation were the removal of Jewish discrimination in Par-

liament membership, the transfer of India's administration from the East India Company to the crown, and the Reform Bill of 1867.

He disliked the drudgery of office and as Conservative leader seemed weak and indolent beside Benjamin Disraeli, who nonetheless admitted, "He abolished slavery, he educated Ireland, he reformed parliament." He is chiefly remembered as epitomizing the aristocratic amateur; he excelled in whatever he did: as racehorse owner, as a benevolent if autocratic landowner, and as a scholar who won the chancellor's Latin verse prize at Oxford and published a blank verse translation of the *Iliad* (1864). He nurtured the Conservatives and helped the protectionists survive difficult years, while he educated them to accept Disraeli as his successor and to prepare for electoral victory.

Derby ware, porcelain figures and service-ware made in Derby, central England, c. 1750–1848. The best known early figures were characterized by glaze retractions about the base. Known as "dry-edge" figures, their modelling and execution was excellent, the porcelain soft and heavy; a pair known as the "Florentine Boars," after Italian bronzes, is the most noted example.

In 1756 William Duesbury established another factory at Derby. Advertising itself as "the second Dresden," it produced finely modelled, palely coloured figures often imitative of Chelsea (with which it was often confused) and Meissen wares. Flowers and colourful insects were favourite decorations of the service-ware. After Duesbury purchased the Chelsea works in 1770, a design trend away from Rococo porcelain toward the Neoclassical began;

"The Pig," a Derby soft-paste porcelain group, Chelsea-Derby period, c. 1780; in the Victoria and Albert Museum, London

By courtesy of the Victoria and Albert Museum, London

during the last decades of the century the painting of the wares achieved a marked excellence, while the unglazed (biscuit) figures, some based on those produced at Sèvres, Fr., became the most delicate and expensive of the Derby wares. Duesbury died in 1786; in 1815 the factory was leased, and c. 1845 many of the molds were sold. In general, the 19th-century works were inferior to those produced earlier. The modern Royal Crown Derby factory dates from 1875.

Derbyshire, administrative, geographic, and historic county in the East Midlands of England. The administrative, geographic, and historic counties cover successively larger areas. The administrative county comprises eight districts: Amber Valley, Bolsover, Derbyshire Dales, North East Derbyshire, South Derbyshire, and the boroughs of Chesterfield, Erc-

wash, and High Peak. Matlock is the administrative centre of the county. The geographic county includes the city of Derby, which forms an independent unitary authority. The district of High Peak includes the north Langdendale area, which belongs to the historic county of Cheshire. The historic county of Derbyshire includes the area around Beighton and Mosborough, administratively part of the metropolitan borough of Sheffield, and the areas around Rocester east of the River Dove and Burton-upon-Trent east of the River Trent, both in the East Staffordshire district of the administrative county of Staffordshire.

Topographically the county may be divided into two sections: a northern upland region, culminating in the Peak District, and a smaller southern lowland area around Derby. A large part of the county's northwestern portion lies within Peak District National Park. The Pennine uplands reach their southern end in the Derbyshire Dome of northern Derbyshire. The dome is a plateau area of limestone flanked by gritstones. In the north the dome forms the heather- and peat-covered plateaus of Kinder Scout and Bleaklow. Coal measures outcrop on the dome's eastern portion with economically important coal seams. In the southern part of the county, marls and pebble beds, sometimes overlain with boulder clay, form rolling countryside. The River Derwent joins the River Trent southeast of Derby.

There are many prehistoric remains in the county, including the important Paleolithic site at Creswell Crags and the early Bronze Age site Arbor Low, near Youlgreave. The Romans established a military network of roads and forts in Derbyshire; their only clearly non-military site is at Buxton, the Roman spa town *Aquae Arnemetiae*. The Romans also exploited the lead deposits found in the area.

With the coming of the Anglo-Saxons, Derbyshire formed part of the kingdom of Mercia. In 873 the Danes captured Repton, a Mercian religious centre, and later settled in the area and founded the borough of Derby. Derbyshire remained a largely pastoral county, with some mining and quarrying, until the 18th century. Lead from the Peak area was in great demand during the Middle Ages.

The iron ores of eastern Derbyshire began to be exploited on a considerable scale in the 17th century, and the county's industries developed further in the 18th century. The first modern factory in England, a silk mill in Derby, was built in 1717, and in 1771 Sir Richard Arkwright opened the first water-powered cotton-spinning mill at Cromford. The valleys of Derbyshire became important sites for textile mills in the 18th and early 19th centuries. The eastern and southern coalfields were intensively exploited in the 19th century. Derby became an engineering centre, and in 1908 Rolls-Royce Ltd. (founded 1906) established its first factory there.

The county's traditional industries declined in the 20th century. Engineering and chemical industries remain important, and limestone quarrying around Buxton and Wirksworth provides about one-fifth of the national production. In addition to its attractive countryside, Derbyshire is richly endowed with great houses dating from the 15th century onward. Among the best-known of these are Haddon, Hardwick, Chatsworth, Bolsover, Sudbury, and Sutton Scarsdale. Area administrative county, 985 square miles (2,551 square km); geographic county, 1,015 square miles (2,629 square km). Pop. (1998 est.) administrative county, 734,300; geographic county, 970,100.

Derbyshire Dales, district, administrative and historic county of Derbyshire, England. About half of the district lies within the scenic Peak District National Park.

The Romans mined lead in the area between Wirksworth and Castleton, and lead mining continued until the 19th century. Cotton textiles became important when Sir Richard Arkwright built the first water-powered cotton-spinning mill at Cromford in 1771.

Among the many historic buildings in the district are the great houses of Chatsworth, Haddon, and Sudbury. Area 307 square miles (795 square km). Pop. (1998 est.) 70,700.

derebey (Turkish: "valley lord"), any of several feudal lords in Anatolia who, from the early 18th century, became virtually independent of the Ottoman central government. After these feudatories disappeared in the 19th century, the term came to designate great hereditary landlords in southern and eastern Turkey who exercised "quasi-feudal" rights over the peasants.

The financial and military obligations of the *derebeys* to the central government came to be well defined: in time of war they served, with their own men, in the Ottoman armies and were given titles by the sultan, as deputy lieutenant governors and tax collectors. They were, however, independent within their territories, where they struck deep roots and formed local dynasties with strong loyalties. Moreover, not threatened by short tenures, as were appointed governors, they were able to undertake long-term policies concerning the well-being of their people and the development of trade.

The reliance of the Ottoman government on *derebey* assistance during the 1768–74 Russo-Turkish War increased their influence, and, during the reign of Selim III (ruled 1789–1807), they not only controlled most provinces of Anatolia but also played an important part in Ottoman affairs. During the reign of Sultan Mahmud II (1808–39), however, the power of most *derebeys* was broken, and their administrative functions were taken over by appointed governors from Istanbul. The process of centralization continued after Mahmud's death (1839), and in 1866 a military expedition subjugated the remaining *derebeys* in the Çukurova region.

Derekh Eretz, also spelled **DEREKH EREZ** (Hebrew: "correct conduct," or "way of the land"), in Judaism, the decorum, dignified behaviour, and gentlemanly conduct that should characterize a Jew at all times. Rabbinic scholars have applied the notion, for example, to all aspects of family life and marriage, to the qualities expected of a scholar, and to relationships between friends. *Derekh Eretz* applies also to one's manner of speaking, of eating, and of dressing and imposes on everyone the obligation of supporting himself so that others will not be unduly burdened. *Derekh Eretz* manifests itself in politeness toward others, whoever they be, and in genuine concern for their welfare. For Jews, *Derekh Eretz* is not only postulated in the Torah (the Law); without it, the Torah itself is rendered sterile. Two independent treatises have been written on the subject, both appended to the Babylonian Talmud: *Derekh Eretz Rabba* ("the Great") and *Derekh Eretz Zu'a* ("the Minor").

Deren, Maya, original name **ELEANORA DERENKOWSKY** (b. April 29, 1917, Kiev, Ukraine—d. Oct. 13, 1961, New York, N.Y., U.S.), influential director, often called the "mother" of American avant-garde filmmaking, whose films offer insight into the human body and psyche and demonstrate the potential of film to explore these subjects.

Deren was educated at the League of Nations School in Geneva, Switz., and at Syracuse University (1933–35), where she became active in the socialist movement. She graduated from New York University in 1936 and received an M.A. in literature from Smith College, Northampton, Mass., in 1939. She met Czech filmmaker Alexander Hammid in 1941;

they were married the following year. The couple codirected *Meshes of the Afternoon* (1943), shot in their own home, with Hammid serving as cinematographer and Deren playing the central character. The film's innovative camera work and narrative structure depict dream events that move between subjective and objective experience. An influential work, it has been credited with establishing the avant-garde movement in the United States. Deren completed five more films before her death and left several unfinished works.

She traveled to Haiti in 1947 to research and film *voudoun* culture. Although she never completed her planned film on the subject, her book, *Divine Horsesmen: The Living Gods of Haiti* (1953), was a well-regarded ethnographic study. Deren also lectured, taught, and wrote extensively on independent film. Her major theoretical work, *An Anagram of Ideas on Art, Form and Film*, was published in 1946.

Deringer, Henry (b. Oct. 26, 1786, Easton, Pa., U.S.—d. 1868), American gunsmith who was the inventor of the Deringer pistol. He was the son of Henry Deringer, Sr., a colonial gunsmith who made Kentucky rifles.

The younger Deringer began his career as an apprentice to a firearms maker in Richmond, Va. In 1806 he settled in Philadelphia and began his own arms-manufacturing plant. He won contracts to supply various types of guns to the United States government. His early percussion-cap pistols were long-barreled weapons that were designed to fit a belt. After 1825 he concentrated on making single-shot pistols. His small caplock pocket pistol became his most famous product. This pistol was easy to handle and accurate at short ranges. It was less than six inches long and was bored in calibres from .36 to .45, with .41 being the most common. This model was copied by many other manufacturers and was quite popular between the 1840s and the American Civil War. It was manufactured and sold into the late 20th century by Colt and others, often in .22 calibre, and sometimes gold-plated.

John Wilkes Booth used a Deringer pocket pistol to assassinate President Abraham Lincoln. A reporter assembling the details called the gun a "Derringer" pistol in his story, adding an extra "r." This incorrect spelling was widely repeated, and the pistol became known as the derringer.

derivative, in mathematics, the rate of change, or instantaneous velocity, of a function with respect to a variable.

Geometrically, the derivative of a function can be interpreted as the slope of the graph of the function or, more precisely, as the slope of the tangent line at a point. Its calculation, in fact, derives from the slope formula for a straight line, except that a limiting process must be used for curves. The formula for the

Graph 1

slope of a straight line is $(y_1 - y_0)/(x_1 - x_0)$, or $[f(x_0 + h) - f(x_0)]/h$, if h is used for $x_1 - x_0$ and $f(x)$ for y (see Graph 1). For a curve, this ratio will depend upon where the points are chosen, reflecting the idea that a curve has a different slope at different points. To find the slope at a desired point, the choice of the second point needed to calculate the ratio represents a difficulty, because, in general, if the second point is far from the first, the ratio will represent an average slope along the portion of the curve cut off, rather than the slope at either point (see Graph 2). To get around this difficulty, a limiting process is used whereby the second point is not fixed but specified by a variable, as h in the ratio for the straight line above. Finding the limit (*q.v.*) in this case is a process in which a number is found that the ratio (also called the difference quotient) approaches as h approaches 0, so that the limiting ratio will represent the actual slope at the given point.

Graph 2

Some manipulations must be done on the quotient $[f(x_0 + h) - f(x_0)]/h$ so that it can be rewritten in a form in which the limit as h approaches 0 can be seen more directly. In finding the derivative of x^2 when x is 2, the quotient is $[(2 + h)^2 - 2^2]/h$. By expanding the numerator, the quotient becomes $(4 + 4h + h^2 - 4)/h = (4h + h^2)/h$. Both numerator and denominator still approach 0, but if h is not actually zero but only very close to it, then h can be divided out, giving $4 + h$, which is easily seen to approach 4 as h approaches 0.

To sum up, the derivative of $f(x)$ at x_0 , written as $f'(x_0)$, $(df/dx)(x_0)$, or $Df(x_0)$, is defined as

$$\lim_{h \rightarrow 0} [f(x_0 + h) - f(x_0)]/h$$

if this limit exists.

Differentiation—*i.e.*, calculating the derivative—seldom requires the use of the basic definition but can instead be accomplished through a knowledge of the three basic derivatives, the use of four rules of operation, and a knowledge of how to manipulate functions. See differentiation.

Derivatives are involved in all phases of calculus and differential equations and find applications in problems of velocity, maxima, curve analysis, and approximations.

dermal leishmaniasis: see Oriental sore.

dermatitis, also called ECZEMA, an inflammation of the skin. Dermatitis is usually characterized by redness, swelling, blister formation, and oozing and almost always by itching. The term eczema, which formerly referred to the blistered, oozing state of inflamed skin, has by

common usage come to have the same meaning as dermatitis.

Dermatitis may be classified into several types. Contact dermatitis results from contact of the skin with an irritating substance or a substance to which the person is allergic. The inflammation can result from contact with a strong acid or alkali or some other chemical, or it can result from contact with innocuous substances (*e.g.*, cosmetics, soap, clothing) which are not primarily irritating in themselves but which produce a reaction in a person who has been sensitized by repeated exposure to them. The most common cause of contact dermatitis in the United States and some other countries is poison ivy. Many other plants can cause the condition. Chemical compounds that may cause contact dermatitis include such metals as nickel and chromium, certain aniline dyes, and many types of drugs. The prevention of contact dermatitis rests upon the identification of the particular irritant and subsequent avoidance of it.

Atopic dermatitis is a disorder of infants, children, and young adults. It is characterized by a redness, thickening, and scaling of the skin in patches, typically on the face, neck, hands, and feet, in the crook of the elbow, or behind the knee. The skin becomes extremely dry, and this leads to itching. The cause of atopic dermatitis is not known, but it tends to run in families whose members have hay fever and asthma.

Stasis dermatitis is a skin inflammation affecting the ankles and lower legs. The condition is caused by chronic poor blood flow in the veins and particularly by varicose veins. The poor blood flow brings about swelling and a progressively more acute irritation of the skin that may lead to ulceration. Stasis dermatitis can be prevented if steps are taken early to improve the blood circulation of the legs, such as wearing supportive stockings or having surgery performed on the varicose veins.

Seborrheic dermatitis is a scaly skin condition that most frequently affects the scalp, dandruff being the common name for the skin particles that scale off the scalp. The condition generally involves body areas that are rich in sebaceous, or oil-secreting, glands, and it can also affect the forehead and eyebrows, midface, the area behind the ears, and the armpits. Most individuals with seborrheic dermatitis tend to have an oily skin. During infancy, seborrheic dermatitis may commonly manifest itself as a yellowish scaling of part of the scalp, a condition referred to as cradle cap.

Neurodermatitis refers to a skin inflammation that is apparently caused by the patient's own repeated and chronic scratching of an itchy area of his skin.

dermatology, medical specialty dealing with the diagnosis and treatment of diseases of the skin. Dermatology developed as a subspecialty of internal medicine in the 18th century; it was initially combined with the diagnosis and treatment of venereal diseases, because syphilis was an important possible diagnosis in any skin rash. Modern dermatology emerged in the early 20th century, after the discovery of an effective drug therapy for syphilis.

Because of the ease of observation of cutaneous symptoms, dermatology had early become a separate branch of medicine. Its scientific basis, however, was not established until the mid-19th century by the Austrian physician Ferdinand von Hebra. Hebra emphasized an approach to skin diseases based on the microscopic examination of skin lesions. Following Hebra's work, dermatologists concentrated chiefly on the description and classification of skin diseases, but a new emphasis on the biochemistry and physiology of these diseases, begun by Stephen Rothman in the 1930s, led to the development of more

sophisticated and effective treatments in the latter half of the 20th century. Dermatologists have gained the capacity to control fungal diseases of the skin, to recognize and treat skin cancers at an early stage, to control the life-threatening skin diseases pemphigus and lupus erythematosus, and to alleviate psoriasis.

dermatomyositis, chronic degenerative inflammation of the skin and voluntary muscles, particularly the muscles of the shoulders and the corresponding muscles of the pelvis. The affected muscles are painful and weakened. The face and neck may be reddened, and there may be a violet coloration of the upper eyelids and the skin around the eyes. Calcium commonly is deposited in the affected skin and muscles. When the skin is not affected or is only slightly affected, the disorder is termed polymyositis (*q.v.*). In 10 to 20 percent of the adults in whom both skin and muscle are affected, cancer is present (for example, in the breast, stomach, ovary, or kidney); removal of the cancer may cause the dermatomyositis to regress. The course of the disease is highly variable. Children with dermatomyositis usually react more favourably to corticosteroid treatments than do adults. Significantly fewer adults than children with the disease survive.

dermestid beetle, any member of the approximately 700 species of the widely distributed insect family Dermestidae (order Coleoptera). These important household pests are usually brown or black, although some are brightly coloured or patterned. They vary in shape from elongated to oval, range in size from 1 to 12 mm (up to 1/2 inch), and are covered with either hairs or scales that easily rub off. The wormlike larvae, the only beetle larvae that are covered with hair, feed on furs, skins, feathers, horn, and hair, causing more damage than the adults.

The larger beetle larva (*Dermestes lardarius*) feeds on cheese and dried meats, especially ham and bacon. The adult beetle is oval, black or brown with yellowish bands and dark spots, and 6 to 7.5 mm long. The beetles are usually discovered inside a house when the adult emerges from its pupal stage and is seen around windows trying to get outside to feed on pollen.

Larder beetle (*Dermestes lardarius*)

Javier Palau Soler—Ostman Agency

The red-brown or golden-brown carpet beetle larva (*e.g.*, *Anthrenus*) is about 5 mm long and very destructive; it attacks fur, furniture, rugs, carpets, and clothing. The oval adults feed on pollen, are usually between 2.2 and 3.5 mm in length, have brightly coloured scales, and resemble ladybird beetles.

Anthrenus verbasci and *A. musaeorum* are two important museum pests; they feed on and have destroyed collections of stuffed mammals, birds, and insects. Museums and private collectors must either have pestproof

display shelves or continuously apply pesticides to protect their collections. The larvae of carrion-feeding species are sometimes used in museums and by taxidermists to clean the soft tissue attached to animal skeletons.

Dermestid beetle (*Trox scabrosus*)

William E. Ferguson

The khapra beetle (*Trogoderma granarium*), a small beetle native to the Indian subcontinent, is a serious pest in most parts of the world. It is unique among dermestids because the larvae feed on stored grain.

dermis, also called **CORIUM**, the thicker, deeper layer of the skin underlying the epidermis and made up of connective tissue. It is present in varying degrees of development among various vertebrate groups, being relatively thin and simple in aquatic animals and progressively thicker and more complex in terrestrial species.

The dermis from its earliest evolutionary appearance has been a depository of bone, as expressed in dermal armour (primitive fishes), scales (fishes and certain amphibians), and plates (crocodile, lizard, turtle, armadillo). The fin rays of fishes are dermal derivatives, as are many types of pigment cells. The dermis of mammals is of greater thickness relative to the epidermis than is that of other vertebrates, partly because it contains abundant collagenous connective tissue. When treated with tannic acid, the dermis becomes leather.

In humans the dermis projects into the overlying epidermis in ridges called papillae. Nerves that extend through the dermis and end in the papillae are sensitive to heat, cold, pain, and pressure. Sweat glands and oil glands lie in the deeper stratum reticulare, as do the bases of hair follicles, the nail beds, and blood and lymph vessels.

Dermoût, Maria, in full HELENA ANTONIA MARIA ELISABETH DERMOÛT-INGERMANN (b. June 15, 1888, Pekalongan, Java, Dutch East Indies [now in Indonesia])—d. June 27, 1962, Noordwijk, Neth.), Dutch novelist and short-story writer known for her subtle and evocative portraits of colonial life in the Dutch East Indies.

Dermoût, who was the descendant of employees of the Dutch East Indies Company, spent her childhood on a sugar plantation in central Java. She attended school in The Netherlands but returned to the islands as a young wife and remained there most of her life.

Her work was not published until she was in her 60s. Her first two novels, *Nog pas gisteren* (1951; *Yesterday*) and *De tienduizend dingen* (1955; *The Ten Thousand Things*), are fictionalized accounts of her youth. Although written in an economic style, the two novels are rich in details of island life as experienced by both the colonials and the native people. Among Dermoût's other books are three volumes of short stories—*De juwelen haarkam* (1956; "The Jeweled Haircomb"), *De sirenen* (1963; "The Sirens"), and *De kist; en enige*

verhalen (1958; "The Wooden Box: A Unique Account")—and a book of sketches, *Spel van Tifagongs* (1954; "Tifagong's Play"). Her work is critically acclaimed not only for its clarity but for its sensitive account of colonialism co-existing with a lush, primitive beauty and power.

Derrida, Jacques (b. July 15, 1930, El Biar, Algeria—d. Oct. 8, 2004, Paris, France), French philosopher whose critical analyses of Western philosophy and of the nature of language, writing, and meaning were highly controversial yet immensely influential in virtually every field of humanistic study in the late 20th century.

Life and work. Derrida was born to Sephardic Jewish parents in French-governed Algeria. Educated in the French tradition, he went to France in 1949, studied at the elite École Normale Supérieure (ENS), and taught philosophy at the Sorbonne (1960–64), the ENS (1964–84), and the École des Hautes Études en Sciences Sociales (1984–99), all in Paris. From the 1960s he published numerous books and essays and taught and lectured throughout the world, attaining an international celebrity comparable to that of Jean-Paul Sartre a generation earlier.

Derrida is best known as the principal exponent of deconstruction (*q.v.*), a term he coined for the critical examination of the fundamental conceptual distinctions, or "oppositions," inherent in Western philosophy since the time of the ancient Greeks. These oppositions are characteristically "binary" and "hierarchical," involving a pair of terms in which one member of the pair is assumed to be primary or fundamental, the other secondary or derivative. Examples include nature and culture, speech and writing, mind and body, presence and absence, inside and outside, literal and metaphorical, and form and meaning, among many others. To "deconstruct" an opposition is to explore the tensions and contradictions between the hierarchical ordering assumed or asserted in the text and other aspects of the text's meaning, especially those that are indirect or implicit. Such an analysis shows that the opposition is not natural or necessary but a product, or "construction," of the text itself.

In three works published in 1967—*Writing and Difference*, *Of Grammatology*, and *Speech and Phenomena*—Derrida explored the treatment of writing by the philosophers Edmund Husserl and Jean-Jacques Rousseau and the psychoanalyst Sigmund Freud, among other figures. Later books included analyses of writing and representation in works by Plato, Hegel, Husserl, and Martin Heidegger. Derrida's work on literature examined avant-garde writers such as Jean Genet, Stéphane Mallarmé, Francis Ponge, and James Joyce. In later works, Derrida took up a host of issues in politics, psychoanalysis, law, ethics, aesthetics, and literature, and he addressed the question of Jewishness and the Jewish tradition in *Shibboleth* and the autobiographical "Circonfession" (1991; "Circumfession").

Criticism. Derrida's writings are known for their extreme subtlety, their meticulous attention to detail, and their tenacious pursuit of the logical implications of supposedly "marginal" features of texts. Nevertheless, his work has met with considerable opposition among some philosophers, especially those in the Anglo-American tradition. In 1992, the proposal by the University of Cambridge to award Derrida an honorary doctorate generated so much controversy that the university took the unusual step of putting the matter to a vote by the dons (Derrida won); meanwhile, 19 philosophers from around the world published a letter of protest in which they claimed that Derrida's writing was unintelligible and his arguments either trivial or false. Despite such criticism, Derrida's ideas remain a powerful force in philosophy and myriad other fields.

derringer, also spelled DERINGER, pocket pistol produced in the early 19th century by Henry Deringer (*q.v.*), a Philadelphia gunsmith.

Derry (Northern Ireland): see Londonderry.

Deruta ware, outstanding tin-glazed earthenware, or majolica, produced during the first half of the 16th century in the town of Deruta on the Tiber River, near Perugia, Italy. Deruta ware is characterized especially by a unique mother-of-pearl, metallic lustre and by certain decorative features. In the art of lustre, Deruta potters, who introduced an iridescent gold lustre decoration, may be held second only to the potters of Gubbio. Although Deruta majolica displays most of the decorative features common in the Renaissance, it is innovative in at least two respects: the molding of plates with a design in slight relief, the lower part coloured dark to give an even more lustrous effect; and the division of the broad borders of the plates into panels with alternating geometric stripes. These dishes, illustrating subjects from

Lustered majolica dish from Deruta, Italy, 1515; in the Victoria and Albert Museum, London

mythology or religion, are at times somewhat harsh and heavy, and the designs of vases and jars are sometimes flat or crude, but, at its most successful, Deruta majolica has a distinctive flamboyance.

Derviş Mehmed Zilli (Ottoman traveler): see Evliya Çelebi.

dervish, Arabic DARWĪSH, any member of a Šūfī (Muslim mystic) fraternity, or tariqa. Within the Šūfī fraternities, which were first organized in the 12th century, an established leadership and a prescribed discipline obliged the dervish postulant to serve his sheikh, or master, and to establish a rapport with him. The postulant was also expected to learn the *silsilah*, the spiritual line of descent of his fraternity.

The main ritual practiced by the dervish is the dhikr, which involves the repeated recitation of a devotional formula in praise of Allah as a means of attaining an ecstatic experience. The rituals of the Šūfī brotherhoods stress the dervishes' attainment of hypnotic states and ecstatic trances through ritual recitation and through such physical exertions as whirling and dancing. Dervishes can be either resident in community or lay members, both of these groups being generally drawn from the lower classes. In the Middle Ages, dervish communities played a vital role in religious, social, and political life in the central Islāmic lands, but their monasteries now are often under government control, and their theological standing is discounted by orthodox theologians. A wandering or mendicant dervish is called a fakir (faqir).

Derwent, River, river in North Yorkshire, England, that rises on Fylingdales Moor only 6 miles (10 km) inland from the North Sea

but flows 57 miles (92 km) through alternating gorges and vales to its junction with the River Ouse. This peculiar course results from the blockage of its former path by an ice sheet. Glacial overflow channels were cut through the tabular hills around Hackness at Langdale and Forge Valley and the Hawardian Hills near Malton. In contrast, the course through the vales of Pickering and York over thick glacial outwash and lacustrine deposits is strikingly flat. The name was recorded by Bede in the 8th century as *Deruentionis fluvii*, from the Celtic "river where oak trees grow abundantly."

Derwent River, river in Tasmania, Australia, rising in Lake St. Clair on the central plateau and flowing 113 miles (182 km) southeast to enter Storm Bay through a 3.5-mile- (5.5-kilometre-) wide estuary. Its major upper-course tributaries, the Jordan, Clyde, Ouse (now draining the Great Lake), and Dee, are extensively developed for hydropower. Hops are grown on irrigated alluvial terraces along its middle course, while in the rich farming area around New Norfolk fruit orchards predominate. The city of Hobart is situated on the estuary, 12 miles (19 km) from the river's

in the 17th century; in the 19th and early 20th centuries mining increased with the completion of railroad lines to Newcastle upon Tyne and other nearby ports. By the late 20th century, however, coal mining had declined, and in 1980 the steelworks at Consett closed. Former mining villages dot the countryside, but the scars of coal mining have been removed. The district's other sizable town, Stanley, 6 miles (10 km) east of Consett, has textile industries. Area 105 square miles (271 square km). Pop. (1991 prelim.) 84,800.

Derzhavin, Gavrila Romanovich (b. July 3 [July 14, New Style], 1743, Kazan province, Russia—d. July 8 [July 20], 1816, Zvanka, Novgorod province, Russia), Russia's greatest and most original 18th-century poet, whose finest achievements lie in his lyrics and odes.

Born of impoverished nobility, Derzhavin joined the army as a common soldier in 1762 and was made an officer in 1772. In 1777 he entered the civil service in St. Petersburg, and during the next 26 years his posts included those of provincial governor at Olonets and Tambov, senator, and minister of justice. His *Oda k Felitse* (1782; "Ode to Felicia"), addressed to Catherine the Great, gained her

is controversial; it is possibly a French corruption of the Indian name for the river, Moin-gona, or it may be derived from the French *de moyeu* ("middle"), being midway between the Missouri and Mississippi rivers. When the state capital was moved there from Iowa City in 1857, its growth was assured. The capitol

mouth. This stretch of the river forms an excellent deepwater port and is spanned by the Tasman Bridge. The river was sighted and named Rivière du Nord by the French admiral Bruni d'Entrecasteaux in 1793 and later that same year was renamed after the River Derwent in England.

Derwent Water, lake, county of Cumbria, England, in the Lake District National Park. It is about 3 miles (5 km) long and from 0.5 to 1.25 miles (0.8 to 2 km) wide. Its maximum depth is 72 feet (22 m). The River Derwent enters its southern end from Borrowdale, its mountain-girded upper valley, and leaves the lake's northern end near the market town of Keswick, at the foot of Skiddaw. Several sites on the well-wooded shores are the property of the National Trust and are frequented by tourists. Lords Island, one of several in the lake, was once the residence of the earls of Derwentwater.

Derwentside, district, county of Durham, northeastern England. It is located in the north-central part of the county, about 12 miles (20 km) southwest of the city of Newcastle upon Tyne. Derwentside was a historically important coal-mining (mostly for coking) area of Great Britain encompassing an outlying section (400 to 1,000 feet [120 to 305 m] high) of the northeastern Pennines. Surface mining, often on the sides of steep hills, began

favour, and he was briefly her private secretary. His liberal political inclinations put an end to his career in 1803, at which time he retired to his estate at Zvanka.

Derzhavin preserved the grandeur and solemnity of the classical ode as practiced in Russia but made it less restrictive and more lyrical and personal in its tone and subject matter. His odes are notable for passages of magnificent imagery. Derzhavin worked in many other poetic genres, and his poems express both lofty and idealistic moralism and his strongly sensual appreciation of life. His work helped to break down the strictures of the classical poetic genres. His lyrics and odes include *Nasmert knyazya Meshcherskogo* (1779; "On the Death of Prince Meshchersky"), *Bog* (1784; "Ode to the Deity"), and *Vodopad* (1791-94; "The Waterfall").

Des Moines, city, capital of Iowa, U.S., and seat (1845) of Polk county, in the south-central part of the state, in the heart of the Corn Belt. It is the focus of a metropolitan area that includes West Des Moines, Urbandale, and Pleasant Hill. Fort Des Moines was established in 1843 at the juncture of the Raccoon and Des Moines rivers to protect the rights of the Sauk and Fox Indians. The area was opened to white settlers in 1845. East Des Moines developed and by 1856 had amalgamated with Fort Des Moines to form the present city. The origin of the place-name

(1871-96), in revived classical Roman style, stands in an 80-acre (32-hectare) park.

From 1910 to 1920 Des Moines expanded rapidly because of the development of local coal deposits. The state's largest city, it is a communication hub and also a major insurance, wholesaling, retailing, manufacturing (notably tires and farm implements), governmental, and publishing centre (especially for farm journals). Des Moines is the site of Drake University (1881), Grand View College (1896), College of Osteopathic Medicine and Surgery (1898), and the KRNT Theatre (one of the nation's largest theatres). Also in the city are the Iowa State Fair Grounds with Heritage Village (displaying early farm machinery and replicas of pioneer buildings) and the Iowa Museum of Agriculture. Living History Farms in Urbandale features a Pioneer Farm of 1840, a Horse Farm of 1900, and a modern farm. Inc. town, 1851; city, 1857. Pop. (1992 est.) city, 195,752; Des Moines MSA, 398,124.

Des Moines Register, The, morning daily newspaper published in Des Moines, Iowa, one of the most influential regional newspapers in the United States.

It was founded in 1860. It absorbed its older competitor, the *Des Moines Leader* (founded as the *Iowa Star* in 1849) in a merger in 1902, becoming the *Register and Leader*. In the following year, Gardner Cowles, Sr., bought the paper; in 1908 Cowles purchased an evening daily, the *Des Moines Tribune* (1906), and publication of both papers—the morning *Register* and the evening *Tribune*, each with a separate editorial staff—continued under the Des Moines Register and Tribune Company. By 1927 the two remaining local competitors, the *Daily News* and the *Capital*, had merged with the *Tribune*, which was later discontinued.

The *Des Moines Register* became famous for its editorials, its outstanding statewide news coverage, and its editorial cartoons. Its editorial cartoonist, Jay Norwood ("Ding") Darling, was widely syndicated in the early 20th century. In 1925 Cowles engaged statistician George Gallup to survey reader preferences—a precursor to the Gallup Poll of public opinion.

Des Moines River, river rising in Lake Shetek in southwestern Minnesota, U.S., near Pipestone, and flowing 525 mi (845 km) in a southeasterly direction to join the Mississippi River 2 mi southwest of Keokuk, Iowa. Above

Humboldt, Iowa, the river is known as the West Fork. The East Fork and the Raccoon River are its principal tributaries. For a distance of 25 miles (40 km) above its mouth, the river serves as the boundary between Iowa and Missouri. Along its course, the river falls 1,375 feet (419 m) and drains an area of 15,807 square miles (40,940 square km).

From the late 1830s until the close of the American Civil War, the Des Moines River was the main artery of commerce for central Iowa. A decline in river traffic came with the development of railroads. The river was early utilized for power, and, although none survive, 80 mills for grinding grain were built along its banks between 1840 and 1890. The Red Rock and Saylorville dams were authorized in 1958 for flood control. Major riparian cities include Ottumwa, Des Moines, Fort Dodge, and Estherville, all in Iowa.

Des Périers, Bonaventure (b. c. 1500, Arnay-le-duc, France?—d. c. 1544, Lyon), French storyteller and humanist who attained notoriety as a freethinker.

In 1533 or 1534 Des Périers visited Lyon, then the most enlightened town of France and a refuge for many liberal scholars. He assisted Robert Olivétan and Lefèvre d'Étaples in the preparation of the vernacular version of the Old Testament and Étienne Dolet in the *Commentariorum linguae Latinae*. Margaret of Angoulême, queen of Navarre, made him her valet de chambre in 1536. He acted as her secretary and transcribed her *Heptaméron*; some maintain that he in fact wrote the work.

The free discussions permitted at Margaret's court encouraged a license of thought as displeasing to the Calvinists as to the Roman Catholics; it became skepticism in Des Périers's *Cymbalum Mundi* (1537; *Cymbalum Mundi: Four Very Ancient Joyous and Factions Dialogues*), a brilliant and violent attack upon Christianity. The allegorical form of its four dialogues in imitation of Lucian did not conceal its real meaning, and the Sorbonne was able to have it suppressed (c. 1538), but it was reprinted in Paris in the same year. His book made many bitter enemies for Des Périers, who prudently left Paris and settled at Lyon. Tradition has it that he killed himself in 1544, but this is questionable.

His collected works, published in 1544, include his poems, the *Traité des quatre vertus cardinales après Sénèque* ("Treatise on the Four Cardinal Virtues After Seneca"), and a translation of Plato's *Lysis*. *Novelles récréations et joyeux devis* (*The Mirrour of Mirth and Pleasant Conceits, or Novel Pastimes and Merry Tales*), the collection of stories and fables on which his fame rests, appeared at Lyon in 1558. The stories are models of simple, direct narration in the vigorous, witty, and picturesque French of the 16th century.

Des Plaines, city, northwestern suburb of Chicago, Cook county, Illinois, U.S., on the Des Plaines River. Originally called Rand—for Socrates Rand from Massachusetts, who settled there in 1835—it was renamed after the river (French: "of the plains") in 1869. In 1925 Des Plaines annexed the village of Riverview. The community was primarily residential until the development in the 1950s of O'Hare International Airport to its south stimulated its industrial growth. The main campus of Oakton Community College was moved to Des Plaines in 1980. Inc. village, 1873; city, 1925. Pop. (1993 est.) 54,427.

Des Plaines River, river rising in Kenosha county, southeastern Wisconsin, U.S., and flowing south into Illinois through the northwestern suburbs of Chicago to Lyons. It then continues southwest past Lockport and Joliet, where it joins the Kankakee River after a

course of 110 miles (177 km). The Illinois River is formed by the confluence of the Des Plaines and Kankakee rivers.

In fur-trading days the Chicago River was linked by a short portage to the Des Plaines and Mississippi rivers. In 1900 the Metropolitan Sanitary District of Greater Chicago completed a drainage canal from the south branch of the Chicago River to the Des Plaines River at Joliet, where it joined the Illinois and Michigan Canal (completed 1848). The construction of the sanitary canal reversed the flow of the Chicago River, permitting water from Lake Michigan to flow through the canal into the Des Plaines River and thence to the Illinois River. The opening of the Illinois Waterway in 1933 allowed modern barge traffic to pass between the Great Lakes and the Mississippi River.

Des Prés, Josquin (Renaissance composer); see Josquin des Prez.

Desaguadero River (Nicaragua): see San Juan River.

Desai, Morarji, in full MORARJI RANCHHODJI DESAI (b. Feb. 29, 1896, Bhadeli, Gujarat province, India—d. April 10, 1995, Bombay), prime minister of India (1977–79), first leader of sovereign India not to represent the long-ruling Congress Party.

The son of a village teacher, Desai was educated at the University of Bombay and in 1918 joined the provincial civil service of Bombay as a minor functionary. In 1930 he resigned to join Mohandas Gandhi's civil-disobedience movement and spent almost 10 years in British jails during the struggle for independence. During the 1930s and '40s he alternated prison service with ministerial posts in the government of Bombay, rising to the chief ministerial post in 1952. He gained a reputation for administrative skill as well as for harshness.

In 1956 Desai was named commerce and industry minister in the Indian government, for which he worked in high capacities until 1963, when he resigned. He became deputy prime minister in 1967. In 1969 he again resigned to become chairman of the opposition to Indira Gandhi and the Congress Party. He was arrested in 1975 for his political activities and detained in solitary confinement until 1977, whereupon he became active in the Janata Party, a coalition of four smaller parties. That same year, Prime Minister Indira Gandhi unexpectedly held elections after a 19-month suspension of political processes, and Janata achieved a surprising and overwhelming victory. Desai was chosen to be prime minister as a compromise candidate among Janata's leaders. After two years of political tension the Janata coalition began to unravel. Desai announced his resignation on July 15, 1979, after numerous defections from the coalition in Parliament, to avoid a vote of no confidence.

"De," "la," and similar components of a name, when followed by a space, are alphabetized as separate words (e.g., *De Forest, Lee*).

When they are joined to the following part of a name, the combination is treated as a single word (e.g., *DeForest, John William*).

Desaix de Veygoux, Louis-Charles-Antoine, also called CHEVALIER (knight) DE VEYGOUX (b. Aug. 17, 1768, near Riom, France—d. June 14, 1800, Marengo [Italy]), French military hero who led forces in the German, Egyptian, and Italian campaigns of the French Revolutionary Wars (from 1792).

The son of Gilbert-Antoine Desaix, Seigneur de Veygoux, he was known at first as the Chevalier de Veygoux. A regular officer, he was compromised and imprisoned following Louis

XVI's deposition, but he had the remarkable good fortune in 1793–94 of being retained and promoted to general by the deputies with the Army of the Rhine, in spite of orders from revolutionary Paris. He demonstrated his worth in Germany in battles at Strasbourg (1793), Mainz (1794), Mannheim (1795), and Bavaria (1796) and in the retreat through the Black Forest. After being wounded at the passage of the Rhine River in 1797, he went to Italy to see Napoleon and in his *Journal de voyage* (ed. by A. Chuquet, 1907) admirably described the army and its chiefs. Desaix led a division to Egypt in 1798, and after the Battle of the Pyramids he occupied upper Egypt against tough opposition from the Mamlūk Murad Bey.

Napoleon did not take Desaix back to France but called for him when he was evacuating Egypt. Desaix was captured at sea and could not reach Napoleon until June 11, 1800, in Piedmont. Sent at once with two divisions toward Genoa, he had not gone far (because of floods) when he was called to the battlefield of Marengo (June 14). He was beginning the counterattack, which turned the battle to victory, when he was shot through the heart.

desalination, also called DESALTING, the removal of dissolved salts from seawater and in some cases from the brackish waters of inland seas, highly mineralized groundwaters (e.g., geothermal brines), and municipal waste waters. This process renders such otherwise unusable waters fit for human consumption, irrigation, industrial applications, and various other purposes. Existing desalination technology requires a substantial amount of energy, and so the process is expensive. For this reason, it is generally used only where sources of fresh water are not economically available.

The desalting of seawater is an ancient notion. Aristotle described an evaporation method used by Greek sailors of the 4th century BC. An Arab writer of the 8th century AD produced a treatise on distillation. In the 19th century the development of steam navigation created a demand for noncorroding water for boilers; the first patent for a desalination process was granted in England in 1869. The same year, the first water-distillation plant was built by the British government at Aden, to supply ships stopping at the Red Sea port. The first large still to provide water for commercial purposes was built in 1930 in Aruba, near Venezuela.

Distillation remains the most widely used desalination process. Either a multiple-effect or a flash evaporator may be used. The first consists of a series of evaporators in which salt water is heated and vaporized in long, vertical tubes. The hot vapour is used to heat salt water entering the next evaporator; in doing so, the vapour is cooled and condensed into fresh water. Because the multiple-effect evaporator reuses heat, it requires less fuel to treat incoming water than a single evaporator.

In flash evaporation, heated seawater is sprayed into a tank kept under reduced pressure. At this reduced pressure, the water vaporizes at a lower temperature, so that flash evaporators require less heat and thus less fuel. Multistage-flash distillation systems consist of a series of flash chambers operating at decreasing pressures. Such systems are more efficient and have greater capacity than single-stage units, and so are employed in very large desalination plants, such as the facility at al-Jubayl in Saudi Arabia that can produce 4,660,000 cubic m (1,232,000,000 gallons) of desalted water per day.

In regions where salt water and intense sunlight are both abundant, a simple distillation apparatus can be used. The heat of the Sun partially vaporizes salt water under a transparent cover; on the underside of the cover, the vapour condenses and flows into a collecting trough. The principal difficulty in this process

is concentrating the energy of the sunlight within a small area.

Membrane processes are usually used with brackish inland water, the salt content of which, though undesirable, is considerably below that of seawater. One such process is reverse osmosis, by which brine, subjected to pressure, is forced against a membrane; fresh water passes through while the concentrated mineral salts remain behind.

Another membrane process, electro dialysis, uses electrical potential to drive the positive and negative ions of the dissolved salts through separate semipermeable membranous filters, leaving fresh water between the filters.

Several desalting processes make use of the fact that when salt water is frozen, the ice crystals contain no salt. In practice, however, objectionable amounts of salt water remain trapped between the crystals, and the amount of fresh water needed to wash the salt water away is comparable to the amount of fresh water produced by melting the crystals.

In the late 20th century, more than 8,000,000 cubic m (2,112,000,000 gallons) of fresh water were produced each day by several thousand desalination plants throughout the world. Distillation processes are used in about half of all the plants and account for roughly three-quarters of the world's desalted water. Most of the other plants employ membrane processes. The world's desalination capacity expanded rapidly during the 1970s and '80s as the oil-rich countries of the Middle East improved their standard of living, with attendant changes greatly increasing the consumption of fresh water. The Middle Eastern countries produce about 75 percent of all the world's desalinated water. The United States produces about 10 percent, and Europe and Africa each account for approximately 5 percent. The world's largest desalination plants are in the Arabian Peninsula.

Desargues, Girard (b. March 2, 1591, Lyon, Fr.—d. October 1661, France), French mathematician who introduced the principal concepts of projective geometry.

As an engineer, Desargues was a technical adviser to the cardinal de Richelieu and the French government. According to René Descartes's biographer, Adrien Baillet, Desargues served at the siege of La Rochelle in 1628, where he met Descartes. About 1630 Desargues became part of a group of mathematicians in Paris whose most noted member was Marin Mersenne. Desargues's *Traité de la section perspective* ("Treatise on the Perspective Section"), containing his theorem on the perspective of two triangles, was published in 1636 but was not appreciated by his contemporaries.

Desargues's most important work, *Brouillon project d'une atteinte aux événemens des rencontres d'un cône avec un plan* (1639; "Proposed Draft of an Attempt to Deal with the Events of the Meeting of a Cone with a Plane"), presents innovations in projective geometry as applied to the theory of conic sections. It significantly influenced one of his disciples, the French mathematician Blaise Pascal. Unfortunately, Desargues embodied in his *Brouillon project* a unique system of mathematical terms derived from botanical names and failed to include Cartesian symbolism, thus ensuring two centuries of obscurity for his work. Only with the discovery of a handwritten copy in 1845 and the ensuing rebirth of interest in projective geometry was his contribution fully recognized. He also published a short manual on musical composition (1636) and a treatise on stonemasonry (1640).

Desargues's theorem, in geometry mathematical statement discovered by the French mathematician Girard Desargues in 1639 that motivated the development, in the first quarter of the 19th century, of projective geometry by another French mathematician, Jean-Vic-

Desargues's theorem

tor Poncelet. The theorem states that if two triangles ABC and $A'B'C'$, situated in three-dimensional space, are related to each other in such a way that they can be seen perspectively from one point (i.e., the lines AA' , BB' , and CC' all intersect in one point), then the points of intersection of corresponding sides all lie on one line (see Figure), provided that no two corresponding sides are parallel. Should this last case occur, there will be only two points of intersection instead of three, and the theorem must be modified to include the result that these two points will lie on a line parallel to the two parallel sides of the triangles. Rather than modify the theorem to cover this special case, Poncelet instead modified Euclidean space itself by postulating points at infinity, which was the key for the development of projective geometry. In this new projective space (Euclidean space with added points at infinity), each straight line is given an added point at infinity, with parallel lines having a common point. After Poncelet discovered that Desargues's theorem could be more simply formulated in projective space, other theorems followed within this framework that could be stated more simply in terms of only intersections of lines and collinearity of points, with no need for reference to measures of distance, angle, congruence, or similarity.

Desbordes-Valmore, Marceline (b. June 30, 1786, Douai, Fr.—d. July 23, 1859, Paris), French poet and woman of letters of the Romantic period.

Marceline Desbordes-Valmore, detail of a drawing by Carrière, 1823

By courtesy of the trustees of the British Museum, photograph, J.R. Freeman & Co Ltd

Her family was ruined by the French Revolution and moved to the French colony of Guadeloupe. She returned to Paris upon her mother's death, supporting herself by acting at the Opéra-Comique and the Odéon. She married a second-rate actor, Prosper Lanchantin, called Valmore.

When illness threatened her stage voice, Desbordes-Valmore turned to writing. Her poetry—*Pauvres Fleurs* (1839; "Poor Flowers"), *Les Pleurs* (1833; "The Tears"), and *Bouquets et prières* (1843; "Bouquets and Prayers")—

is poignant and elegiac and concerns religion, sadness, death, and the author's love for her daughters and her native Douai. Her prose work *L'Atelier d'un peintre* (1833; "A Painter's Studio") is autobiographical. The poet Charles Baudelaire esteemed her writing, and Paul Verlaine admitted his debt to her, giving her a place in his *Poètes maudits* (1884; "Damned Poets").

Desborough, John, Desborough also spelled DESBOROW, or DISBROWE (baptized Nov. 13, 1608, Eltisley, Cambridgeshire, Eng.—d. 1680, London), English soldier, Oliver Cromwell's brother-in-law, who played a prominent part in Commonwealth politics.

Desborough married Cromwell's sister Jane in June 1636. He was a member of Cromwell's cavalry regiment at the beginning of the Civil War and distinguished himself in succeeding campaigns. He fought at the Battle of Worcester (September 1651) as major general and almost captured Charles II near Salisbury.

During the Commonwealth, Desborough held many high offices and was a member of the Parliaments of 1653, 1654, and 1656. In 1655 he was the major general in charge of administering the six western counties of England. In spite of his near relationship to Cromwell, Desborough violently opposed the suggestion that Cromwell should assume the crown. After Cromwell's death he was, with Charles Fleetwood, the chief instigator and organizer of the hostility of the army toward Richard Cromwell's administration and forced Cromwell to dissolve his Parliament in April 1659.

After the Restoration Desborough escaped to the Netherlands, where he engaged in republican intrigues. He was ordered home in April 1666, on pain of incurring the charge of treason, and was imprisoned in the Tower of London from July 1666 to February 1667.

descant (from Latin *discantus*, "song apart"), also spelled DISCANT, counter melody either composed or improvised above a familiar melody. Descant can also refer to an instrument of higher-than-normal pitch, such as a descant recorder. In late medieval music, discantus referred to a particular style of organum featuring one or more countermelodies added to a newly rhythmicized plainsong melody. Discantus in this sense is usually spelled discant in English translation.

Descartes, René, LATIN RENATIUS CARTESIUS (b. March 31, 1596, La Haye, Touraine, Fr.—d. Feb. 11, 1650, Stockholm, Swed.), French mathematician, scientist, and philosopher who has been called the father of modern philosophy. He radically distinguished between the mind, which he perceived as indubitable, and the body (or matter in general), which he explained on the basis of purely mechanistic principles. The axiom *Cogito, ergo sum* ("I think, therefore I am") is his most famous formulation.

A brief treatment of René Descartes follows. For full treatment, see MACROPAEDIA: Cartesianism, Descartes and.

An exceptionally intelligent boy, Descartes was sent at the age of eight to the newly opened Royal College at La Flèche, where for 10 years he received a Jesuit education, revealing a marked inclination toward mathematics. In 1616 he took a degree in law at the University of Poitiers. In 1618 Descartes joined the army of the Prince of Orange in Holland, where he met Isaac Beekman, who exposed him to many recent developments in mathematics. After a period of travel, he joined for a time the army of the Duke of Bavaria in 1619, in the early stages of the Thirty Years' War. It was in March of that year that he first described the idea of a unitary universal

science that would link all possible human knowledge together into an all-embracing wisdom. On November 10, according to Descartes, a visionary dream revealed the nature of this science more clearly. Interpretation of this episode has remained controversial. Descartes's life continued to remain peripatetic until 1628, when he moved to Holland, where he was to live, except for short absences, until 1649.

During this period in Holland he composed the works that made him famous in his own time and influenced succeeding ages. The *Discours de la méthode* (1637; *Discourse on Method*), his most widely read work, sets forth four rules for the pursuit of knowledge: to accept nothing as true unless clearly recognized as such; to solve problems systematically by analyzing them part by part; to proceed from simple to more complex considerations; and to review everything thoroughly to make sure that nothing has been omitted. In addition, the *Discourse* presents the metaphysical foundations of his doctrine. The universal application of doubt it describes culminates in the self-evident certainty (*cogito ergo sum*) from which all his philosophical propositions derive. The *Méditationes de prima philosophia* (1641; *Meditations on First Philosophy*) further develops the metaphysical doctrine of the *Discourse*. The *Principia philosophiae* (1644; *Principles of Philosophy*) attempts to give a logical account of all natural phenomena in one single system of mechanical principles. *Les Passions de l'âme* (1649; *Passions of the Soul*) outlines his ethical views.

In September 1649 Descartes left Amsterdam to serve as instructor to Queen Christina of Sweden. He died the following winter of complications from a severe chill.

descent, the system of acknowledged social parentage, which varies from society to society, whereby a person may claim kinship ties with another. If no limitation were placed on the recognition of kinship, everybody would be kin to everyone else; but in most societies some limitation is imposed on the perception of common ancestry, so that a person regards many of his associates as not his kin.

The practical importance of descent comes from its use as a means for one person to assert rights, duties, privileges, or status in relation to another person, who may be related to the first either because one is ancestor to the other or because the two acknowledge a common ancestor. Descent has special influence when rights to succession, inheritance, or residence follow kinship lines.

One method of limiting the recognition of kinship is to emphasize the relationships through one parent only. Such "unilineal" kinship systems, as they are called, are of two main types—patrilineal (or agnatic) systems, in which the relationships through the father are emphasized; and matrilineal (or uxorial) descent systems, in which the maternal relationships are stressed.

In systems of double unilineal descent, patrilineal and matrilineal principles operate in the same society, and there are two series of enduring groups, a person belonging to groups in each series. Ambilateral (or ambilineal) descent systems are those in which membership in a kinship group may be claimed through either parent.

Unilineal systems differ radically from so-called cognatic systems, in which everyone has obligations and duties of much the same kind toward both his paternal and maternal kin and, conversely, can expect rights and privileges from them. Thus, whereas in a matrilineal, for example, a person would feel cousin obligations only to the children of his mother's siblings, in a cognatic system he is

in some sense allied to the children of both parents' siblings. The practical significance of this cognatic system may be either that an individual establishes claim on another person of common descent or that he enjoys some status or privilege by virtue of his lineage or descent. Both structurally and in terms of rights and duties, the cognatic system is vague and tends to characterize the more industrialized countries, in which individual rights and duties are defined to an increasing extent institutionally or legally.

Deschamps (de Saint-Amand), Émile (b. Feb. 20, 1791, Bourges, Fr.—d. April 23, 1871, Versailles), poet prominent in the development of Romanticism.

Deschamps's literary debut came in 1818, when, with Henri de Latouche, he produced two plays. Five years later, with Victor Hugo, he founded *La Muse française*, the journal of the Romantic, and the preface to his *Études françaises et étrangères* (1828) formed a manifesto of the movement. His translations of *Romeo and Juliet* (1839) and *Macbeth* (1844), though never performed, were also important. He wrote several libretti, notably that for Berlioz' *Roméo et Juliette*, and his prose works include *Contes physiologiques* (1854) and *Réalités fantastiques* (1854).

Deschamps, Eustache, byname MOREL (French: "Nightshade") (b. c. 1346, Vertus, Fr.—d. c. 1406), poet and author of *L'Art de dictier* (1392), the first treatise on French versification.

The son of middle-class parents, Deschamps was educated in Reims by the poet Guillaume de Machaut, who had a lasting influence on him. After law studies in Orléans, he held administrative and diplomatic posts under the kings Charles V and VI. His leisure was devoted to poetry, and he was immensely prolific, producing farces, traditional love poetry, and satires—notably a satire on women.

By his own description, Deschamps was jovial and good-humoured. The Hundred Years' War embittered him, however, and his later poetry is a realistic reflection of his times, showing sympathy for the sufferings of the people and affection for his country. He influenced the English poet Geoffrey Chaucer, to whom he addressed a ballade.

Deschanel, Paul(-Eugène-Louis) (b. Feb. 13, 1855, Brussels—d. April 28, 1922, Paris), French political figure who was an important parliamentary leader during the Third Republic and served as its 10th president (Feb. 17 to Sept. 20, 1920).

Deschanel was a brilliant student of philosophy, law, and literature who chose to combine journalism and politics for a career. After a brief term in the prefectural administration, he was elected to the Chamber of Deputies from the Eure-et-Loir *département* (1885). He took a seat with the Progressive Republicans and concentrated on social problems and foreign affairs. He was elected to the Académie Française in 1899 and throughout his life continued to write books on politics and lit-

Deschanel
H. Roger Viollet—Hartingue

erature, including *La Question sociale* (1898), *Orateurs et hommes d'état* (1888), *Essai de philosophie politique* (1899), and *Gambetta* (1920).

Deschanel served two terms as president of the Chamber of Deputies (1898–1902; 1912–20). When he was elected president of the republic, he was the first person with no prior ministerial experience to attain that post. His brief term was marked by ministerial instability and his own deteriorating health, which forced his resignation after only seven months.

descloizite, vanadate mineral containing lead, copper, and zinc that usually forms brownish red to blackish brown crusts of intergrown crystals or rounded fibrous masses; its physical appearance is varied, however, and specimens have been found in shades from orange-red to black and various greens. The chemical formula for descloizite is $(Zn,Cu)PbVO_4(OH)$. Descloizite forms a solid-solution series with the similar mineral mottramite, in which copper replaces zinc in the crystal structure. These minerals occur with vanadinite in the oxidized zone of copper and lead deposits, as in the Otavi region, Namibia, where they are abundant; San Luis Potosi, Mex.; Baden, Ger.; and New Mexico. For detailed physical properties, see vanadate mineral (table).

descriptive ethics: see comparative ethics.

Dese, also spelled DESSYE, or DESSIE, town, central Ethiopia, situated on the western escarpment of the Great Rift Valley at an elevation of 7,500 feet (2,300 m). Dese (Amharic: "My Joy") is a commercial and communica-

Drying skins in Dese, Eth.
Victor Englebert—De Wys Inc

tions centre, 16 miles (25 km) northwest of Kembolcha, which is at the junction of roads to Asmera, Addis Ababa, and Aseb. Dese is a long-established market for grains, oilseeds, hides, skins, honey, and beeswax and a distribution centre for imported goods. It also has artisan industries and flour mills. Pop. (1984 prelim.) 68,848.

Deseado River, Spanish RÍO DESEADO, river in southern Argentina, rising in Buenos Aires Lake in the Andes of southern Chile and Argentina. It flows generally eastward and south-eastward through Santa Cruz province. Near Koluel Kayke and Jaramillo it sometimes disappears into the dry soils of Patagonia, but it reemerges and empties into the Atlantic at Puerto Deseado. The total length of the Deseado is approximately 380 miles (610 km). It is used for irrigation along its lower course.

desensitization, also called HYPOSENSITIZATION, treatment that attempts to eliminate allergic reactions, as of hay fever or bronchial asthma, by a series of injections in graded strengths of the substance to which the person is sensitive (e.g., pollen, house dust). Extracts of the material to be injected are purified and put into an alkaline buffer solution, to which epinephrine (adrenaline) is often added to

minimize local inflammatory reactions. The first injections contain little antigen, but, as desensitization progresses, more and more is added. A three-month program of injections often suffices for hay-fever sufferers, but asthmatics may require a longer program.

Desensitization is successful in about 80 percent of hay-fever sufferers and up to 90 percent of asthmatics; treatment is more effective in persons with a few, well-defined allergies than in those allergic to many substances. The success of desensitization is attributed to special antibodies, called blocking antibodies, that appear in the serum after treatment and combine preferentially with allergen. This prevents the reaction of allergen with allergic antibodies in the skin and precludes an allergic reaction. Desensitization can also be required when a penicillin-sensitive person contracts a disease such as bacterial endocarditis, which is best treated with penicillin. *See also* allergy; anaphylaxis; antibody; antigen.

Deseret News, The, daily newspaper published in Salt Lake City, Utah, by the Church of Jesus Christ of Latter-day Saints (Mormons). It was founded as a biweekly in 1850. The word Deseret means "Land of the Honey Bee," according to the Book of Mormon, and was to have been the name of the anticipated Mormon state. *The Deseret News* was forced to move from Salt Lake City to Fillmore, Utah, during the armed conflicts of 1857–58. Partly because newsprint was scarce, *The Deseret News* did not become a daily until 1867. It is one of the few successful religious dailies in the English language. In addition to church news *The Deseret News* carries world news, much of it from news agencies.

desert, any large, extremely dry area of land with fairly sparse vegetation. It is one of the Earth's major types of ecosystems, supporting a community of distinctive plants and animals specially adapted to the harsh environment.

A brief treatment of deserts follows. For full treatment, *see* MACROPAEDIA: Biosphere. For a detailed discussion of the topographic features associated with the desert environment (such as sand dunes) and the processes respon-

sible for their evolution (such as wind erosion), *see* Continental Landforms; Geomorphic Processes.

The level of aridity commonly used to delimit desert areas is a mean annual precipitation value equal to 250 mm (10 inches) or less.

Desert terrain in Death Valley, California, showing (front to back) badlands, the valley floor, and the Panamint Range

© Larry Ulrich/DRK PHOTO

Approximately 5 percent of the Earth's land surface receives such limited rainfall. Deserts are concentrated in high-latitude, circumpolar areas and in two discontinuous, Earth-girdling bands at middle and low latitudes. The high-latitude cold deserts include the perennial ice deserts of Antarctica and Greenland and portions of the seasonally snow- and ice-free tundra of North America and Eurasia. Precipitation is meagre in these polar regions, with various areas receiving only up to about 127 mm (5 inches) annually. The desertlike, rocky, barren lands within the tundra, however, result from complex causes that are partially but not entirely related to aridity, because most tundra areas are adequately supplied with water during the short, cool growing season.

Hot, arid regions furnish examples of the most familiar desert features. These regions

have little physical or biological relationship to cold polar deserts. Tropical deserts, occurring between about 15° and 30° north and south

of the Equator, include the Sahara of northern Africa, the Thar Desert of the Indian subcontinent, the Victoria of Australia, and the Kalahari of southwestern Africa. These deserts owe their origin and location largely to aridity that results from the high moisture-holding capacity of air warmed by compression as it descends from the high-pressure belt of the horse latitudes to the belt of tropical trade winds. Decreased precipitation and extraordinarily high rates of evaporation are the two main factors that combine to desiccate the land, particularly on the western sides of the continents.

The Gobi and Takla Makan deserts of central Asia are deep within continental interiors far from moisture-laden winds, whereas the deserts east of the Andes in southern Argentina exemplify the rain-shadow effect created by high mountains lying across the path of moist winds.

Climatic conditions are characteristically extreme in all deserts, and variations are considerable from one to another. Differences in seasonal temperature regimes sharply differentiate tropical from mid-latitude deserts. Seasonal as well as diurnal temperature ranges are greatest in the latter. For example, in the Gobi, winter winds are violent and severe blizzards common, and parts of this area may have mean temperatures below freezing for as many as six months each year. But during the hottest months the air temperature may average 41° to 43° C (105° to 110° F). A distinguishing characteristic of most arid climates is variability of precipitation. Several years may elapse without any measurable rainfall, only to be followed by a deluge. In general, such variability is inversely related to the mean annual precipitation, increasing as the total rainfall decreases.

Desert terrain may consist of rugged mountains, high plateaus, or plains. A large number of deserts occupy broad mountain-rimmed basins, which are known as bolsons in certain regions. Surface materials in deserts include bare bedrock, plains of gravel and boulders, and vast tracts of shifting sand. Wind-blown sands, commonly thought to be typical of deserts, make up only about 2 percent of North American deserts, 10 percent of the Sahara, and 30 percent of the Arabian desert.

Outside of the polar regions, desert landscapes are primarily shaped by weathering, eolian, and fluvial processes. Rock fragmentation occurs principally as a result of expansion and contraction induced by wide temperature fluctuations. Winds transport enormous

clouds of dust and impel large quantities of sand along the ground, all particles behaving as abrasive tools that carve, facet, and polish rocks. Continued removal of fine materials produces deflation basins with surfaces of residual gravel and boulders. Infrequent rains of high intensity and short duration cause flash floods, which rush from highlands as sheet floods or as torrents raging through usually dry arroyos, or wadis. The streams flow at high velocity and transport large quantities of mud, sand, and rock debris short distances into the desert basins before the water is dissipated by penetration into the ground and by evaporation. The centripetal drainage of bolsons often produces pediments consisting of upper eroded bedrock surfaces and lower undulating slopes of coalescing alluvial fans. Mineral salts leached from the highlands are carried to the centre of the basins, where they accumulate in ephemeral lakes that, lacking outlets to the sea, become increasingly saline.

Plant and animal populations tend to differ qualitatively and quantitatively in various deserts, but all possess physiological and behavioral traits that favour obtaining and conserving a meagre water supply. Plants are primarily low-growing, thorny, small-leaved or leafless, grayish to light green in colour, with extensive and, in most cases, deep roots. Water-conservation adaptations in perennial species include reduced surface areas, daytime closure of stomata, water-impervious cuticles and waxy coatings, and succulent organs that accumulate large quantities of water. Drought-evading, ephemeral annuals, dormant during dry periods, appear in profusion after rains. The dominant xerophytic plants (*i.e.*, those adapted to arid conditions) include agaves, cacti, composites, and yuccas.

Typical desert fauna consists of insects (and other arthropods), reptiles, birds, many rodents, and a few larger mammals. Nocturnal habits are well-developed characteristics among the rodents, but most desert birds and reptiles are diurnal. The majority of animals drink water when it is available, but in its absence they depend on fluids obtained by eating succulent plants or the blood and other tissues of their prey. Many insects and some rodents (*e.g.*, the kangaroo rat and pocket mouse) utilize metabolic water, and even the camel derives a significant water supply from the oxidation of fats accumulated in its hump. Water conservation is accomplished in diverse ways. Reptiles and some insects have water-impervious integuments, mammals concentrate urine by reabsorbing water before excretion, and reptiles excrete nitrogenous waste as uric acid crystals and thus retain water. Nocturnal habits reduce water loss, and some animals, such as the ground squirrel, estivate (enter a torpid state) during extreme heat and drought.

Desert Artesian Basin (Australia): *see* Canning Basin.

Desert cultures, in North America, ancient cultures centred on the Great Basin in the area of Nevada, Utah, and Arizona; they lasted from about 7000 or 8000 BC to about 2000 BC. Subsistence was based on gathering wild seeds and plants and on hunting small game; social groups were probably small and nomadic. The people used baskets, nets, crude milling stones, simple bone tools, and stemmed or notched chipped-stone projectile points. *See also* Cochise culture.

desert dormouse: *see* Selevin's mouse.

Desert Fathers, early Christian hermits whose practice of asceticism in the Egyptian desert, beginning in the 3rd century, formed the basis of Christian monasticism. One of these hermits, Pachomius of the Thebaid

(c. AD 290–346; *see* Pachomius, Saint), who organized nine monasteries for men and two for women, is credited with being the founder of cenobitic (communal) monasticism in the Western world.

Following the example of Jesus' life of poverty, service, and self-denial, the early monks devoted themselves to vows of austerity, prayer, and work. Believers who chose to go into the desert as hermits were said to be answering the call of Christ: "Jesus said to him, 'If you would be perfect, go, sell what you possess and give to the poor, and you will have treasure in heaven; and come, follow me'" (Matthew 19:21). *See* monasticism.

desert palace, any country dwelling built in Syria, Jordan, and Palestine by Umayyad (AD 661–750) rulers and aristocrats.

At one time the complexes were thought to be rural retreats for nomadic rulers and members of ruling families who tired of city life, but, because all of these desert residences now seem to have been located on irrigated estates, in military encampments, and at trade centres, they appear to have served as forts and

Qasr 'Amrah, desert palace east of Amman, Jordan, dating to c.710–750

hunting lodges as well. Besides living quarters, most include a mosque, baths, and an official hall that may have been a throne room or an entertainment room.

Many of the remaining palaces are known for their rich decoration, which often resembles, in larger scale, the patterned textiles used to ornament nomadic tents. The elaborate vaults and domes of the baths at Khirbat al-Mafjar, the limestone frieze at Mshatta, and the frescoes at Qasr 'Amrah (all in Jordan) and the carved stucco facade of Qasr al-Hayr (Syria) are some of the best-known features of the extant desert palaces.

desert pavement, surface of angular, interlocking fragments of pebbles, gravel, or boulders in arid areas. Desert pavement forms on level or gently sloping desert flats, fans, or bajadas and lake and river terraces of Pleistocene age (10,000 to 1,600,000 years old).

The percolation of infrequent precipitation tends to cause lateral and downslope movement of silt particles beneath the surface of the ground. This leads to the concentration of gravel, a process enhanced by the constant removal of fine sediment at the surface by wind action. Gravel concentrations in desert areas are sometimes called lag gravels, in reference to the residue left by the removal of fine material. Thus, pavements are produced by the combined effects of water and wind. Evaporation and capillarity draw soil moisture to the surface and may precipitate calcium carbonate, gypsum, and other salts that cement the pebbles together to form a desert con-

glomerate. The pebbles often are so packed and smooth that no more wind deflation can occur; such areas in the Sahara generally are followed by caravan routes. A similar area is the hammada, in which wind has removed most of the material, leaving only bare rock surfaces scattered with large rocks.

Desert Rats, byname of THE SEVENTH ARMOUR'D DIVISION, a group of British soldiers who helped defeat the Germans in North Africa during World War II. The Desert Rats, led by General Allen Francis Harding, were especially noted for a hard-fought, three-month campaign against the more experienced German Afrika Korps, led by General Erwin Rommel ("The Desert Fox").

The term "Rats of Tobruk," a moniker applied by the Nazi propagandist broadcaster William Joyce ("Lord Haw-Haw"), referred more generally to any of the Allied troops (including Australian, British, and Polish units) who defended Tobruk, Libya.

desert varnish, also called PATINA, thin, dark red to black mineral coating (generally iron and manganese oxides and silica) deposited on pebbles and rocks on the surface of desert regions. As dew and soil moisture brought to the surface by capillarity evaporate, their dissolved minerals are deposited on the surface; studies indicate that the varnish materials generally are extracted from the surrounding rock and earth material. Wind abrasion removes the softer salts and polishes the patina to a glossy finish. The rate of varnish formation varies: it generally is thought to take about 2,000 years for it to form in arid areas, because it coats artifacts and natural objects known to be of such antiquity; but it has formed in less than 50 years in the Mojave Desert. Both high evaporation rates and sufficient precipitation are necessary for desert varnish formation.

desertification, also called DESERTIZATION, spread or encroachment of a desert environment into arid or semiarid regions, caused by climatic changes, human influence, or both. Climatic factors include periods of temporary but severe drought and long-term climatic changes toward aridity. Human factors include the artificial alteration of the climate, such as degradation of the biological environment in arid regions by removing vegetation (which can lead to unnaturally high erosion), excessive cultivation, and the exhaustion of surface-water or groundwater supplies for irrigation, industry, or domestic use.

Desertification drains an arid or semiarid land of its life-supporting capabilities. The process is characterized by a declining groundwater table, salinization of topsoil and water, diminution of surface water, increasing erosion, and the disappearance of native vegetation. Areas undergoing desertification may show all of these symptoms, but the existence of only one usually provides sufficient evidence that the process is taking place. Desertification usually begins in areas made susceptible by drought or overuse by human populations and spreads into arid and semiarid regions.

Desertification is not limited to nondesert regions and can occur in areas within deserts where the delicate ecological balance is disturbed. The Sonoran and Chihuahuan deserts of the American Southwest, for example, have become observably more barren as the wildlife and plant populations have diminished.

Public awareness of desertification increased during the severe drought in the Sahel in Africa (1968–73), a drought that accelerated the southward movement of the Sahara (desert). In 1977 the worldwide consequences of desertification were the subject of a UN Conference on Desertification (UNCOD), held in Nairobi, Kenya.

Desgarcins, Magdeleine-Marie, original name LOUISE DESGARCINS (b. 1769, Mont

Dauphin, Fr.—d. Oct. 27, 1797, Paris), one of the greatest of French tragediennes.

Desgarcins made her debut at the Comédie-Française in Jean Racine's *Bajazet* (1788) and was at once made a full member of the company. When the conflicts of the Revolution caused a split in the company in 1791, she and François Talma, with whom she usually appeared, formed a new company in which she triumphed in *King Lear*, *Othello*, and J.-F. de La Harpe's *Mélanie et Virginie*. She died insane.

Desiderio DA SETTIGNANO (b. c. 1430, Settignano, republic of Florence [Italy]—d. January 1464, Florence), Florentine sculptor whose works, particularly his marble low reliefs, were unrivaled in the 15th century for subtlety and technical accomplishment.

"Bust of a Young Lady," marble, by Desiderio da Settignano, c. 1460–64; in the Staatliche Museen Preussischer Kulturbesitz, Berlin

By courtesy of the Staatliche Museen Preussischer Kulturbesitz Berlin-Dahlem

Desiderio was raised in a family of stone masons and entered the Stone and Wood Carvers' Guild of Florence in 1453. Little is known about his education, although he was influenced by the Italian relief sculptor Donatello.

Desiderio's delicate, sensitive, highly original style is perhaps most exquisitely manifest in his sensuous portrait busts of women and children. These lyrical pieces convey a wide range of moods and emotions, from joy and charm to melancholy and pensiveness. His sense of design and highly refined skill as a marble cutter established him as a master of low reliefs. Some of the most notable are his studies of the Madonna and Child, St. John, and Christ as an infant.

Sometime after 1453 Desiderio designed and carved the monument of the humanist Carlo Marsuppini in the Church of Santa Croce in Florence. With its rich architectural detail and its admirable effigy, this tomb is exceptionally important in the history of Florentine wall monuments. He carved the frieze of heads for Filippo Brunelleschi's Pazzi Chapel in Florence sometime after 1451 and completed the marble Altar of the Sacrament in San Lorenzo, Florence (1461), which is considered to be one of the decorative masterpieces of the 15th century.

Desiderio masterfully employed the technique of *rilievo stacciato* (low, or flattened, relief) in a style related to that of Donatello. The delicacy of contrast in his carvings gives his surfaces a glowing, ethereal quality, as seen in his "Angel from the Altar of the Sacrament" (1458–61) and many of his busts of women.

designer drugs, in popular usage, illegal synthetic chemicals, including commonly abused drugs such as ketamine, LSD, PCP, quaaludes, Ecstasy, and methamphetamine.

Designer drugs usually are synthesized for the first time by pharmaceutical companies in an attempt to create an analog of some better known chemical that is safer, more effective, or less expensive to manufacture, and indeed the term "designer drug" originally referred to legal pharmaceuticals. It began to be applied to illegal substances in the 1980s, when authorities in the United States became concerned about the use of synthetic heroins such as fentanyl. The term echoed advertisements for designer jeans and carried connotations of the faddishness and the elite cachet of expensive consumer goods.

Illegal designer drugs arouse alarm because their production in clandestine laboratories thwart efforts to control them by more usual means, such as import restrictions, and because they are thought to pose physical and psychological dangers to users. Some designer drugs are far stronger than the drugs for which they serve as substitutes. Also, errors in the synthetic process can result in substances very different from—and far more deadly than—the desired product.

The possibility of creating different designer versions of the same drug sometimes has made regulation of designer drugs difficult. In the United States this problem was addressed in the Anti-Drug Abuse Act of 1986, which prohibited the manufacture of "substantially similar" analogs of banned chemicals.

In the 1990s there were renewed fears regarding various synthetic drugs, especially Ecstasy and methamphetamine and the so-called "date-rape drugs," chemicals such as GHB (gamma hydroxybutyrate) and Rohypnol, which were used to render potential victims unconscious. (J.P.J.)

Desiosi, Compagnia dei, one of the Italian acting troupes performing *commedia dell'arte* (improvised popular comedy) in the late 16th and early 17th centuries. This period is considered the golden age of the genre, and the performers were noted for their sophistication and varied skills. The Desiosi's director, Diana da Ponti, was well known both as an actress and as a poet. The name Desiosi means "the desired." Cardinal Montalto was the company's patron. Documents of the Desiosi's activities go back to 1581, including tours of Mantua, Cremona, Verona, Milan, Bologna, Genoa, and Rome. The actor Tristano Martinelli, renowned for his portrayal of the mischievous servant Arlecchino, performed with the Desiosi until he left the company to assume a leadership role with the Accesi, another great company of the time.

desk, a table, frame, or case with a sloping or horizontal top particularly designed to aid writing or public reading, and often containing drawers, compartments, or pigeonholes.

Office desk, Herman Miller, Inc., 1950
Photo courtesy of Herman Miller, Inc.

The first desks were probably designed for ecclesiastical use. Early English desks that had derived from the ecclesiastical lectern were massive; after the development of printing, they gave way to smaller, portable chests with sloping lids—called writing boxes—some of

Kneehole desk, French, early 18th century; in the Wallace Collection, London

By courtesy of the trustees of the Wallace Collection, London

which featured drawers and letter holes. The lids on most writing tables and also on the later writing cabinets (with drawers below and cupboards above) were hinged either at the front or back; those hinged at the front often were supported in a horizontal position by slides that could be pulled out of the framework, by hinged stays fixed inside the lid, or by a combination of both. By the late 16th century the writing boxes were usually mounted on stands.

Many desk styles were produced in the 18th century. Small, portable "ladies' desks" became popular in England. In France, where the habit of writing little notes became something of a social mania, the variety was remarkable. During this period, many desks featured ingenious mechanical devices; among the popular desks of the period were the cylinder top and the rolltop desks. The cylinder top was a rigid, quarter-circle shutter covering the interior. The top could be slid back into the body of the desk while, at the same time, a writing surface might be drawn forward. The first rolltop desk was designed for Louis XV.

The kneehole desk was developed in England in the early 18th century. Its top was supported by two banks of cupboards, or drawers, separated by a space for the legs of the person seated at the desk. Larger versions—known as library tables or partners' desks—enabled two people to work facing each other. School desks, popular since early Victorian times, developed from the portable and lectern desks.

Modern desks reflect contemporary styles. Some are little more than writing surfaces with, perhaps, one drawer for the storage of writing materials. Others contain a number of drawers (sometimes accommodating hanging files), units that support typewriters or computer keyboards, and other elements that reflect modern work and home needs. See also bureau; secretary.

Deskey, Donald (b. Nov. 23, 1894, Blue Earth, Minn., U.S.—d. April 29, 1989, Vero Beach, Fla.), American industrial designer who helped establish industrial design as a profession.

Deskey attended the University of California at Berkeley, the Mark Hopkins Institute of Art (now San Francisco Art Institute), and the Art Institute of Chicago before studying in Paris in 1920–22. He became the director of the art department at Juniata College, Huntington, Pa., and later the director of the industrial design department of New York University, where his work received international recognition.

After starting his career in advertising, Deskey began to work on furniture and interior design. His inventive use of industrial materials for decorative purposes brought him acclaim and caught the attention of the Rockefeller Center, Inc., which in 1932 awarded him a large contract for the interior decoration and furnishings for Radio City Music Hall. The extraordinary results of this project helped Deskey firmly establish Donald Deskey Associates, the consulting firm he had founded in 1926.

In addition to package and product designs for major corporations, Deskey's firm produced a number of projects for various world's fairs. His firm also designed the interiors of clubs, restaurants, and hotels in New York City. Deskey invented a high-pressure laminate known as Weldtex.

desktop publishing, the use of a personal computer to perform publishing tasks that would otherwise require much more complicated equipment and human effort. Desktop publishing allows an individual to combine text, numerical data, photographs, charts, and other visual elements in a document that can be printed on a laser printer or more advanced typesetting machine. The primary advantages of desktop publishing over conventional publishing apparatus are low cost and ease of use.

A typical desktop publishing system comprises a personal computer, a video monitor, a high-resolution printer, and various input devices, such as a keyboard, mouse, or digital scanner. Some systems also integrate advanced memory storage units, communication devices, and other peripheral equipment. One of a number of different combinations of software applications is necessary to operate the system. Text and graphic elements are commonly created or manipulated with several separate software programs and then combined with, or copied into, a page-makeup program that allows the user to arrange them into a final composite. More powerful desktop publishing software programs offer full-featured word processing and graphics capabilities.

Deslandres, Henri-Alexandre (b. July 24, 1853, Paris, France—d. Jan. 15, 1948, Paris), French physicist and astrophysicist who in

Deslandres

Hartigue—H. Roger Viollet

1894 invented a spectroheliograph, an instrument that photographs the Sun in monochromatic light. (About a year earlier George E. Hale had independently invented a spectroheliograph in the United States.)

After graduating from the École Polytechnique ("Polytechnic School") in 1874 and spending seven years in the army, Deslandres worked in the laboratories of the École Polytechnique and the Sorbonne. From 1886 to 1891 he studied the spectra of radiation emitted by molecules. Joining the Paris Observatory in 1889, he turned his energies to astrophysics, first studying molecular spectra and then the spectra of planets, the Sun, and other stars. He continued his work at the Meudon Observatory and in 1908 was appointed its director. The Paris and Meudon observatories merged in 1926, and he remained in charge of them until his retirement in 1929.

desman, either of two semiaquatic mammals of the mole family, Talpidae: *Desmana moschata* of slow rivers of southwestern Russia and *Galemys pyrenaicus* of fast streams of

Painting by Donald C. Meighan

the Pyrenees Mountains of Europe. Desmans have long snouts that flare slightly at the tip, webbed hind feet, more or less flattened tails, and dense, brown fur. The Russian desman is 42 cm (17 inches) long, including its 21-centimetre tail; the Pyrenees desman is slightly smaller.

Desmarest, Nicolas (b. Sept. 16, 1725, Soulaines, France—d. Sept. 28, 1815, Paris), French geologist whose discovery of the volcanic origin of basalt disproved the Neptunist theory that all rocks were formed by sedimentation from primeval oceans.

From 1757 Desmarest was employed by the government to help spread better manufacturing methods throughout France. By 1788 he had risen to the post of inspector general and director of manufactures. In 1792, during the French Revolution, Desmarest was imprisoned and narrowly escaped execution; he was later recalled to government service.

In 1763–74 he studied the Auvergne of central France, where he found large basalt deposits that he traced as lava flows from nearby ancient volcanoes. His investigations revealed that many valleys are formed by the erosion of the rivers that flow in them. His numerous maps and essays showing the igneous origin of basalt were instrumental in reforming much of geological theory.

By the time he died, Desmarest had prepared four volumes of a planned five-volume work, *Dictionnaire de géographie physique*, which later appeared, with the posthumously edited fifth volume, in *Encyclopédie méthodique* (1781–1832).

Desmarests, Nicolas, MARQUIS DE MAILLEBOIS, Desmarests also spelled DES MARETS (b. Sept. 10, 1648, Paris, France—d. May 4, 1721, Paris), minister of finance during the last seven years of the reign (1643–1715) of Louis XIV of France.

A nephew of Louis's great finance minister Jean-Baptiste Colbert, Desmarests rose rapidly in financial administration, but on Colbert's

death (1683) he was exiled for his alleged (though unproved) involvement in a counterfeiting scheme. Allowed to return to Paris

Nicolas Desmarests, engraving by C. Randon, 1678, after a painting by Pierre Mignard

By courtesy of the Bibliothèque Nationale, Paris

in 1686, he produced a remarkable series of memoranda exposing France's desperate economic situation. The fiscal crisis became particularly acute after France engaged the Austrians, British, and Dutch in the War of the Spanish Succession (1701–14). In 1703 Louis XIV's finance minister, Michel Chamillart, made Desmarests director of finances; and in 1708 he replaced Chamillart as controller general. He immediately postponed repayment of loans made to the government and obtained a lower rate of interest on some types of loans. In addition, he created a royal lottery, devalued metal currency, and instituted in 1710 a 10 percent tax on income. Although his skillful fiscal measures saw France through the war, the public debt had become unmanageable. In 1715 Desmarests recommended that the state should declare itself bankrupt.

After the death of Louis XIV (September 1715) and the accession of young Louis XV, Desmarests was dismissed from office by the regent Philippe II, Duke of Orléans.

Desmarests de Saint-Sorlin, Jean (b. 1595, Paris, France—d. Oct. 28, 1676, Paris), French prose writer, poet, dramatist, Christian polemicist, and political figure. One of the original members and the first chancellor of the French

Jean Desmarests de Saint-Sorlin, engraving by P. Lombart after a portrait by H. Gaspar

H. Roger Viollet

Academy, Desmarests opened the long literary battle, since called the *querelle des anciens et des modernes* (see ancients and moderns), by arguing that the true models for modern French literature were Romance legends and the Bible rather than classical Greek and Roman writers.

Desmarests had written a number of literary works before the publication of his popular romance *Ariane* (1632) finally gained for him entrance to Parisian literary circles; flattery soon won him the favour of Cardinal de Richelieu, under whose patronage he was

given a succession of important government posts and wrote a number of tragedies and tragicomedies, the best of which was *Les Visionnaires* (1637).

He became a fervent Christian propagandist, directing his intolerance particularly against the Jansenists; his opposition to the ancients was also based on the conviction that literature should reflect Christian conviction. Several works reflected this point of view, among them two works that initiated the debate regarding the ancients and the moderns, *La Comparaison de la langue et de la poésie française avec la grecque et la latine* (1670) and *Défense de la poésie et de la langue française* (1675).

desmid, any of the beautiful, single-celled (sometimes filamentous or colonial), microscopic green algae of the order Zygnematales, class Chlorophyta, characterized by extensive variation in cell shape. Typically the cell is di-

Desmid (*Micrasterias*), highly magnified
Winton Patnode—Photo Researchers

vided symmetrically into semicells connected at a central point. The three-layered cell wall is impregnated with openings or pores and pectin spicules; irregular desmid movement is caused by the flow of a gelatinous substance through these pores. Conjugation (temporary union for the exchange of nuclear material) is the usual method of sexual generation. When a conjugation tube is not formed, the two protoplasts unite in a gelatinous sheath that surrounds the cells. Usually cell division occurs across the contact point, each half develops another semicell, and two complete desmids are formed. Spores are rare. The distribution of desmids is worldwide, usually in acid bogs or lakes. Since most species have a limited range, the presence of specific desmids is helpful in characterizing water samples. One of the more common desmid genera, the sickle-shaped *Closterium*, often contains gypsum crystals.

Desmond, Old Irish DES-MUMA (South Munster), an ancient territorial division of Ireland approximating the modern counties of Kerry and Cork. Between the 11th and 17th centuries, the name was often used for two quite distinct areas. Gaelic Desmond extended over the modern County Kerry south of the River Maine and over the modern County Cork west and north of the city of Cork; Anglo-Norman Desmond extended over north Kerry from the River Maine, over most of the modern county of Limerick, southwest Tipperary, east and south County Cork, and east Waterford. In 1329 Maurice Fitzgerald was created earl of Desmond, and his descendants became almost independent rulers during the 15th century. His line ended in 1601, and the earldom was eventually granted to a member of the English family of Feilding, from 1675 being held in conjunction with that of Denbigh.

Desmond, Gerald Fitzgerald, 14th (or 15th) earl of, byname THE REBEL EARL (b. c. 1538—d. Nov. 11, 1583, Glenageenty, County Kerry, Ire.), Irish Roman Catholic nobleman who led one of the three major Irish rebellions against English rule under Queen Elizabeth I.

The son of James FitzJohn, 13th earl of Desmond, he succeeded to his father's title and lands in Munster (southwestern Ireland) in 1558 and was soon embroiled in territorial disputes with Thomas, 10th earl of Ormonde. The two rivals pleaded their cases before Elizabeth in 1560, but Desmond's manner so provoked the Queen that she had him imprisoned for a short time.

Returning to Ireland in 1564, Desmond quickly took up arms against Ormonde; early in 1565 he was wounded and captured in battle at Affane. The Queen then decided the feud in favour of Ormonde, and when Desmond failed to abide by the agreement he was arrested in 1567 and kept in honourable detention in Dublin and London for six years. During this interval Desmond's cousin James (Fitzmaurice) Fitzgerald launched a rebellion against the English but came to terms in February 1573, shortly before the Earl's release.

Then in July 1579 Fitzmaurice invaded Ireland with a small force of Italians and Spaniards, backed by the Pope and King Philip II of Spain. Desmond did not join them until after Fitzmaurice was killed in August. Desmond took charge of the papal army and appealed to the Irish lords to join in the defense of Catholicism against the English Protestants. The English brutally suppressed the insurgents and then left Ormonde to hunt down Desmond. The death of the Earl in a minor skirmish brought to a close a conflict that had devastated Munster.

Whether Gerald Fitzgerald is designated the 14th or 15th earl depends on an earlier disputed succession.

Desmoulin, (Lucie-Simplice)-Camille (-Benoist) (b. March 2, 1760, Guise, Fr.—d. April 5, 1794, Paris), moderate democrat who was one of the most influential journalists and pamphleteers of the French Revolution.

Desmoulin, portrait by an unknown French artist, 18th century; in the Musée Carnavalet, Paris
Graudon

The son of an official of Guise, Desmoulin was admitted to the bar in 1785, but a stammer impeded his effectiveness as a lawyer. Nevertheless, after the outbreak of the Revolution in 1789, he suddenly emerged as an effective crowd orator, urging a Parisian crowd to take up arms (July 12, 1789). The ensuing popular insurrection in Paris was climaxed with the storming of the Bastille on July 14. Soon thereafter Desmoulin published his pamphlet *La France Libre* ("Free France"), which summed up the main charges against France's rapidly crumbling ancien régime. In addition, his famous *Discours de la lanterne aux Parisiens* ("The Streetlamp's Address to the Parisians"), published in September 1789, supported the bourgeois-democratic reforms of the revolutionary National Assembly and set forth republican ideals.

Two months later Desmoulin launched his lively newspaper *Les Révolutions de France et de Brabant* ("The Revolutions in France and in Brabant"), in which he attacked poli-

cies that were impeding the democratic movement. After Louis XVI's abortive flight from Paris in June 1791, Desmoulin intensified his campaign for the deposition of the King and the establishment of a republic. The assembly retaliated by ordering his arrest on July 22, 1791, but he went into hiding until he was granted an amnesty in September.

Meanwhile, Desmoulin had formed close working relations with Georges Danton in the Jacobin and Cordelier clubs. After participating in the popular insurrection that overthrew the monarchy on Aug. 10, 1792, he was made secretary general under Danton in the Ministry of Justice. Elected to the National Convention, which convened in September, Desmoulin joined the other Montagnards (deputies from the Jacobin Club) in a bitter struggle against the moderate Girondin faction. Desmoulin's *Histoire des Brissotins* ("History of the Brissotins"), issued in mid-May 1793, severely undermined the Girondins' influence by portraying them as agents in the pay of foreign enemies. On June 2 the Montagnards expelled the leading Girondins from the National Convention and took control of the Revolution.

Nevertheless, by December 1793 Desmoulin and Danton had become leaders of a moderate faction—called the Indulgents or Dantonists—within the Jacobin camp. Their chief enemies were Jacques Hébert's left-wing Jacobins who, in alliance with the Parisian lower classes, had forced the National Convention to inaugurate a state-regulated economy and institute the reign of terror against suspected counterrevolutionaries. In the first two issues of his new paper, *Le Vieux Cordelier* ("The Old Cordelier," Dec. 5–30, 1793), Desmoulin attacked the Hébertists for instigating the "de-Christianizing" movement that sought to destroy all Roman Catholic institutions. His friend Robespierre, by now the chief spokesman of the all-powerful Committee of Public Safety, supported this anti-Hébertist campaign, but in the next four issues of his paper Desmoulin lashed out against the committee's use of economic controls and political terror. Robespierre then retaliated by demanding that copies of *Le Vieux Cordelier* be burned (Jan. 7, 1794).

Robespierre had the leading Hébertists guillotined on March 24, and on the night of March 29–30 he acquiesced to the arrest of Desmoulin, Danton, and their friends. Charged with complicity in a "foreign plot," the Dantonists were guillotined on April 5.

Desnos, Robert (b. July 4, 1900, Paris—d. June 8, 1945, Terezín, Czech.), French poet who joined André Breton in the early Surrealist movement, soon becoming one of its most valuable members because of his ability to fall

Desnos
By courtesy of the Editions Gallimard

into a hypnotic trance, under which he could recite his dreams, write, and draw. Texts from this period appeared in the Surrealist review *Littérature* and in his book *La Liberté ou*

l'amour! (1927; "Liberty or Love!"). Humour, tenderness, and eroticism pervade his works, in which acrobatic verbal techniques never detract from the spontaneity of the inspiration. Dreams and reality merge in freely associated images in *Corps et biens* (1930; "Bodies and Goods"). In 1930 he broke from the doctrinaire Surrealist rigidity of Breton and for a decade wrote motion-picture and radio scripts, including the highly successful *Complainte de Fantomas* (1933; "Fantomas' Lament").

Desnos later abandoned the eccentric experiments in Surrealist verse for more traditional and classical forms that made it easier to express his humanitarian sympathies aroused by World War II. His works of this period include *Fortunes* (1942), *État de veille* (1943; "The Wakeful State"), and *Contrée* (1944; "Country"). Arrested for his activity in the Resistance, he was deported and died of typhus shortly after his camp was liberated. A collection including both his early Surrealist poems and later works, *Domaine public* ("Public Domain"), appeared in 1953. *The Selected Poems of Robert Desnos* was published in 1991.

Desnoyers, Auguste-Gaspard-Louis, Baron, original name AUGUSTE-GASPARD-LOUIS BOUCHER-DESNOYERS (b. Dec. 19, 1779, Paris, France—d. Feb. 16, 1857, Paris), French engraver, one of the most eminent line engravers of his time. Desnoyers studied engraving and drawing and, after visiting Italy, entered the studio of Pierre-Alexandre Tardieu in 1800. His fame was established in 1805 by an engraving after Raphael, whereupon Napoleon I commissioned him to reproduce his full-length portrait in coronation robes by Gérard. He became a member of the Institute (1816) and engraver to King Charles X (1825). He is accredited with 75 plates.

Despard, Edward Marcus (b. 1751, County Leix, Ire.—d. Feb. 21, 1803, London, Eng.), British army officer and colonial administrator and organizer of a conspiracy against the British government. Despard entered the army in 1766 and attained the rank of colonel. After serving in Jamaica, he was sent to Central America in 1781; there he was made governor of Roatán Island, off the Honduras coast, and soon afterward of the British Mosquito Coast and Gulf of Honduras.

In 1784 he took over the administration of Belize. There he supported the land claims of recent immigrants from the Mosquito Coast against those of earlier settlers, on whose complaints he was recalled in 1790. Charges against him were dismissed in 1792, but the British government refused to employ him further. He was imprisoned from 1798 to 1800 on no specific charge, though it has been suggested that he was involved in the Irish Rebellion.

Despard then began to organize a conspiracy in which he hoped to combine an army mutiny with a rising in London to assassinate King George III and capture the Tower of London and the Bank of England. His plot became known, and he was arrested. Though Lord Nelson testified in his behalf, he was convicted of high treason and executed.

Despenser, Hugh Le; and Despenser, Hugh Le, in full, respectively, HUGH LE DESPENSER, EARL OF WINCHESTER, and SIR HUGH LE DESPENSER, bynames HUGH LE DESPENSER THE ELDER and HUGH LE DESPENSER THE YOUNGER (respectively b. 1262—d. Oct. 27, 1326, Bristol, Gloucestershire, Eng.; d. Nov. 24, 1326, Hereford, Herefordshire, Eng.), unpopular favourites of England's King Edward II, who were executed by Edward's opponents, Queen Isabella and Roger Mortimer.

Hugh the Elder was summoned to Parliament as a baron in 1295. He fought in France and Scotland for Edward I and was sent by him on

several embassies, including two to the pope. He was one of the few supporters, in 1308, of Piers Gaveston, Edward II's favourite; after Gaveston's death in 1312 he became the king's chief adviser until Thomas, Earl of Lancaster, leader of the baronial opposition, procured his dismissal from court and council in February 1315. He then worked to further the interests of his son, Hugh the Younger, who had been in the king's household when he was prince of Wales. The younger Hugh was appointed the king's chamberlain in 1318, but both father and son were attacked in Parliament by the magnates in 1321; the intense hatred with which the barons regarded the Despensers was due to the enormous wealth that had passed into their hands and to the arrogance and rapacity of the younger Hugh. At last the king was forced to agree to their disinheritance and exile. The elder Hugh went abroad but the younger remained in the Cinque Ports and engaged in piracy.

After the collapse of the opposition at the Battle of Boroughbridge (March 1322), the Despensers returned to power, and the elder Hugh was created earl of Winchester. Hugh the Younger worked to enhance the importance of the chamberlain's office: he diverted to it from the Exchequer the revenue from certain lands, developed it as a department equipped with its own seal and provided private income for the king. But his administration aroused discontent. He had married (1306) Eleanor, coheir of Gilbert de Clare, Earl of Gloucester (d. 1314). Hugh's attempt to acquire the sole inheritance had been foiled by a division of Clare's estates in 1317; but even so he received lands in Glamorgan and Wales. At the rebellion of Queen Isabella and Roger Mortimer (1326), both Despensers fled westward with the king. The elder, sent to defend Bristol, surrendered it to Isabella on October 26 and, after summary trial, was hanged the next day. The younger Despenser was captured with the king and tried and hanged a month later.

Despiau, Charles (b. Nov. 4, 1874, Mont-de-Marsan, France—d. Oct. 30, 1946, Paris), French sculptor who developed a sensitive, classical style akin to that of Aristide Maillol. The nude studies he drew for his sculptures are also highly esteemed.

Despiau was an assistant to Auguste Rodin but came to reject Rodin's Romanticism in

"Paulette," sculpture by Charles Despiau, 1910; in the National Museum of Modern Art, Paris

By courtesy of the Musée National d'Art Moderne, Paris. Cliche Musée National, permission A.D.A.G.P. 1971, by French Reproduction Rights, Inc.

favour of a return to the simplicity of archaic classical sculpture. Modeling principally in plaster but sometimes working in stone, he completed only one large-scale work, a war memorial (1920–22) for the town of his birth.

Though particularly noted for the sensitive characterizations in his portrait busts, Despiau also executed life-size figures, frequently nude. Among his bronzes are "Faunesse" (1924), "Eve" (1925), and "Dominique" (1926). "Asia" (1938) is one of his efforts in terra-cotta.

Desportes, Alexandre-François (b. 1661, Champigneulle, France—d. April 20, 1743, Paris), French painter who specialized in portraying animals, hunts, and emblems of the chase; he was among the first 18th-century artists to introduce landscape studies using nature as a model.

At the age of 12 Desportes was sent by his father to Paris, where he worked and studied in the studio of Nicasiaus Bernaerts, an artist

"Portrait of a Hunter," a self-portrait, oil on canvas by Alexandre-François Desportes, 1699; in the Louvre, Paris

Cliche Musees Nationaux

who taught him to observe nature carefully. Desportes executed small decorative works for other artists, and he enjoyed considerable success at portraiture. Desportes was invited by King John III Sobieski to the court of Poland (1695–96), where he painted a number of portraits of members of the royal family.

When he returned to France, Desportes decided that he could not compete successfully as a portrait painter and began to paint chase and hunt scenes, studies of dogs, and still-life pictures of flowers and fruit. In 1699 he was admitted to the French Royal Academy, and he succeeded in winning the favour of Louis XIV. Desportes became a recorder of royal hunts, and many of his works show the king's favourite dogs. He also worked on decorations for several of the royal châteaux. In 1712 he went to London, where he was much in vogue. Returning to France six months later, he continued to work for the regency and received many commissions under Louis XV. One of his largest projects was the tapestry series "Indies" (1687–1730). In 1735 he was ordered to redo the work, retaining the subject but changing the composition. This appeared as "New Indies."

Desportes, Philippe (b. 1546, Chartres, France—d. Oct. 5, 1606, Abbey of Bonport), French courtier poet whose light, facile verse prepared the way for the new taste of the 17th century in France and whose sonnets served as models for the late Elizabethan poets.

Desportes based his style on that of the Italians—chiefly Petrarch, Ludovico Ariosto, and Pietro Bembo. About 1567 he displaced

Pierre de Ronsard as the favourite poet of Henry, Duke d'Anjou, whom he accompanied to Kraków when Henry was elected king of Poland in 1573. With the publication that year of Desportes' *Premières Oeuvres* ("First

Philippe Desportes, detail of a drawing by an unknown artist
H. Roger-Viollet

Works"), he became Ronsard's rival. Desportes returned to France with Henry on the death of Charles IX (1574). He wrote sonnets and elegies, in graceful alexandrines, for Henry III and others to present to their mistresses. In 1583 he received the livings of the abbeys of Tiron and Josaphat, enjoying the revenues of other benefices also and entertaining an intellectual circle in a princely manner.

His *Dernières amours* (1583; "Last Loves"), also known as *Cléonice*, marks his farewell to secular verse. His translations of the Psalms (1591, 1598, 1603) were attacked by François de Malherbe and vigorously defended by the poet Mathurin Régnier, Desportes's nephew. Desportes is not a personal poet. His elegant poems sound much the same whether they are addressed to his own mistresses or to those of the great. Nonetheless, his clear, harmonious style found ready acceptance by the English poets Edmund Spenser, Michael Drayton, Samuel Daniel, and others.

Dessalines, Jean-Jacques (b. c. 1758, West Africa—d. Oct. 17, 1806, Jacmel, Haiti), emperor of Haiti who proclaimed his country's independence in 1804.

Dessalines was brought to the French West Indian colony of Saint-Domingue (Haiti) as a slave. He worked as a field hand for a black master until 1791, when he joined the slave rebellion that broke out in the colony amid the turmoil caused by the French Revolution. In the decade that followed he distinguished himself as a lieutenant of the black leader Toussaint-Louverture, who established himself as governor-general of Saint-Domingue with nominal allegiance to Revolutionary France. When Toussaint was deposed in 1802 by a French expedition sent by Napoleon Bonaparte to reconquer the colony, Dessalines at first submitted to the new regime. In 1803, however, when Napoleon declared his intention to reintroduce slavery (which had been abolished by the French Convention in 1794), Dessalines and other black and mulatto (racially mixed) leaders rose in rebellion. With British help they expelled the French from Saint-Domingue, and on Jan. 1, 1804, Dessalines, as governor-general, proclaimed the entire island of Hispaniola an independent country under its Arawakan name, Haiti. The following September he adopted the title of emperor as Jacques I.

Dessalines continued many of Toussaint's policies, including the use of forced labour on plantations to prevent reversion to a purely subsistence economy, but he was far more hostile to whites. He confiscated their land, made it illegal for them to own property, and, perhaps fearing them as potential subversives in the event of another French invasion,

launched a campaign of extermination against the country's white inhabitants in which thousands were killed. These massacres, together with his property law (which remained in force for more than a century), effectively prevented any renewal of white dominance over the blacks, who formed more than 80 percent of the population. He also discriminated against the elitist mulattoes and was finally killed trying to put down a revolt under the mulatto leader Alexandre Sabès Pétion, after which Pétion and the black leader Henry Christophe divided Haiti between them.

Dessau, city, Saxony-Anhalt Land (state), east-central Germany, on the Mulde River at its confluence with the Elbe River, northeast of Halle. The German town, which developed from a Sorbian settlement, was first mentioned in 1213. From 1603 until 1918 it was the residence of the counts, princes, and dukes of Anhalt, and it remained the capital of Anhalt Land until 1945. In the 18th century the Anhalt line had a castle built in the Mosigkau district of the town in the southwest; it contains a museum of the Rococo period and a notable collection of paintings. Dessau was the seat of the Bauhaus architectural school under Walter Gropius from 1925 to 1933. Extensive bombing in World War II destroyed many historic buildings. The Landestheater, the town hall, and the Johanniskirche (1690–1702; St. John's Church) have been restored. Moses Mendelssohn, the philosopher, was born (1729) in Dessau.

Dessau was the site of a large aircraft works before World War II; its present industries include a shipyard where dredging machines are produced and vehicle, machinery, apparatus, and chemical works. A railway junction with repair shops, on the Berlin-Belzig-Leipzig line, Dessau also has an inland harbour and an airfield. Pop. (1992 est.) 95,097.

Dessau, Paul (b. Dec. 19, 1894, Hamburg, Ger.—d. June 28, 1979, East Berlin, E.Ger. [now Berlin, Ger.]), German composer and conductor best known for his operas and other vocal works written in collaboration with Bertolt Brecht. Dessau's conducting career included posts in Cologne (1919–23) and Berlin (1925–33). His long collaboration with Brecht began in 1942 in the United States, where he wrote the music (1946) for Brecht's play *Mutter Courage und ihre Kinder* (*Mother Courage and Her Children*), the most popular of the Brecht-Dessau works. From 1948, they continued their partnership in East Germany, where Dessau composed his most successful opera, *Die Verurteilung des Lukullus* (1949; "The Sentencing of Lucullus"; also called *Das Verhör des Lukullus* ["The Trial of Lucullus"]), with libretto by Brecht. Dessau's other works include the opera *Einstein* (1971–73).

dessert, the last course of a meal. In the United States dessert is likely to consist of pastry, cake, ice cream, pudding, or fresh or cooked fruit. British meals traditionally end with nuts, fruits, and port or other dessert wine, while French practice is to end with fruit, cheese, and wine; in both cuisines, a more elaborate meal would include a sweet course preceding the dessert offerings. In Spain, Portugal, and Latin-American countries, desserts of flan (a baked caramel custard) are ubiquitous. Other rich sweets based on eggs, milk, and fruits also are preferred. The elaborate cakes and tarts of central and northern Europe make the dessert course a glory of these cuisines. Indian cuisine offers sweet puddings and dense cakes flavoured with rosewater, honey, and nuts.

In many cuisines, however, there is no usual sweet course; rather, fresh fruit, tea, or coffee constitute the end of the meal. In Japan and China elaborate confections are usually eaten as snacks rather than as part of a meal.

The dessert course reached its zenith in

the banquets of the European courts of the 18th and 19th centuries, when the desire for ostentation and artifice coincided with the widespread availability of refined sugar and flour. On tables decorated with flowers and architectural fantasies in sugar and pastry were presented dozens of creams, tarts, fruits, cakes, pastries, puddings, jellies, and meringues.

Sweet dessert dishes demand sweet wines. Notable among these are sweet port, sherry, and madeira; Tokaj Aszu of Hungary; sauternes; Greek mavrodaphne; and German Auslese, Beerenauslese, and Trockenbeerenauslese bottlings. Sweet or dry liqueurs and brandies also are offered at the meal's close.

Dessie, also spelled **DESSYE** (Ethiopia): *see* Dese.

Dessoir, Ludwig (b. Dec. 15, 1810, Posen, Prussia [now Poznań, Pol.]—d. Dec. 30, 1874, Berlin, Ger.), German actor whose fame rested on his portrayals of Shakespearean characters.

After years of apprenticeship on many stages, Dessoir in 1839 joined the court theatre at Karlsruhe, where he stayed for 10 years. From 1849 to 1872 he was associated with the Berlin court theatre, traveling throughout Germany to give guest performances. In 1855 he played in London, where critics compared his Othello favourably to the portrayals by Edmund Kean and William Charles Macready. His Othello had a quiet intensity that was in marked contrast to the melodramatic violence with which it had become customary to play the Moor.

Destinn, Emmy, original name **EMA KITTL** (b. Feb. 26, 1878, Prague, Austria-Hungary [now in Czech Republic]—d. Jan. 28, 1930, Česká Budějovice, Czech.), Czech soprano noted for the power and vibrant richness of her voice and for her great intelligence and dramatic gifts. She adopted the name of her singing teacher, Maria Loewe-Destinn.

Destinn made her debut in Berlin in 1898 as Santuzza in Pietro Mascagni's *Cavalleria rusticana*. Richard Strauss chose her to create the title role in his opera *Salome* at its premiere (1906) in Berlin and Paris. She first sang at Covent Garden, London, in 1904 as Donna Anna in W.A. Mozart's *Don Giovanni* and in 1908 made a triumphant first appearance at the Metropolitan Opera, New York City, as Aida in Giuseppe Verdi's opera of the same name. Other roles in her extensive repertoire included Minnie in Giacomo Puccini's *La fanciulla del west* (*The Girl of the Golden West*), Pamina in Mozart's *Die Zauberflöte* (*The Magic Flute*), Valentine in Giacomo Meyerbeer's *Les Huguenots*, and Eva in Richard Wagner's *Die Meistersinger*.

Destiny, Stone of: *see* Scone, Stone of.

Destouches, André Cardinal, original name **ANDRÉ CARDINAL** (baptized April 6, 1672, Paris, France—d. Feb. 7, 1749, Paris), French opera composer who brought an original touch to the genres of the day.

André Cardinal was the son of a wealthy Parisian merchant, Etienne Cardinal, Seigneur des Touches et de Guilleville, but he did not take any form of the patronym until 1694, after which he was known as Destouches. He was educated by the Jesuits and traveled with a priest to Siam (Thailand) in 1687–88. Four years later he participated in the siege of Namur as a musketeer, but he left military service in 1694 to pursue a career in music. Destouches' first opera, *Issé*, was produced in 1697. He wrote nine other operas, and in 1713 he was appointed inspector general of the Royal Academy of Music (*i.e.*, the Paris Opéra). In 1728 he became director of that institution, though he abandoned the post two years later. Destouches also wrote two cantatas and several motets.

Destouches, Philippe Néricault (b. April 9, 1680, Tours, France—d. July 4, 1754, Fortoiseau), dramatist who brought to the tradition of French classical comedy influences derived from the English Restoration theatre.

After classical studies in Tours and Paris, Destouches entered the diplomatic service. He was posted to Switzerland and, in 1717, to London. There he became acquainted with English writers and developed an affection for English customs and for Restoration drama. After his return to Paris, he was successful with his comedy *Le Philosophe marié* (1727; *The Married Philosopher*), although his plays were considered too moralistic by many of his contemporaries. His masterpiece is *Le Glorieux* (1732; *The Conceited Count*), which examines the conflict between the nobility and the bourgeoisie.

Destour, byname of AL-HIZB AL-HURR AD-DUSTURI AT-TUNUSI, English TUNISIAN LIBERAL CONSTITUTIONAL PARTY, Tunisian political party, especially active in the 1920s and '30s in arousing Tunisian national consciousness and opposition to the French protectorate.

The forerunner of the Destour, the Young Tunisians, had engaged the Tunisian intellectual elite but lacked widespread support. Forced underground in 1912 after the arrest of its leaders Ali Bash Hamba and Sheikh 'Abd al-Aziz ath-Tha'libi, the Young Tunisians reemerged on June 4, 1920, as the Destour party. Arguing that the legal force of the suspended Tunisian constitution (*dustūr*) of 1861 could still be rightfully reinstated by the Tunisians, they began by advocating complete independence from France. When conservative Tunisians balked at this, they accepted the protectorate temporarily. When the French began encroaching on traditionally Muslim prerogatives in the early 1930s—as by setting up French judges in Tunisian law courts—the Destour organized and led protests, strikes, and boycotts.

The Destour was officially proscribed in May 1933, and in March 1934 some of its younger members broke away to form their own organization, the Neo-Destour (later the Democratic Constitutional Rally). The old Destour made several unsuccessful attempts to regain its influence in the 1940s and '50s before finally passing out of existence in 1957.

Destourian Socialist Party (Tunisia): see Democratic Constitutional Rally.

destroyer, fast naval vessel that has served a variety of functions since the late 19th century. The term destroyer was first used for the 250-ton vessels built in the 1890s to protect battleships from torpedo boats. These torpedo-boat destroyers, as they were called, then became super torpedo boats themselves, so that, by World War I, they were commonly deployed ahead of the battle fleet to scout for the enemy fleet, beat back its destroyers with cannon fire, and then launch torpedoes against its battleships and cruisers.

As the submarine became the principal torpedo-launching vessel, destroyers were equipped with hydrophones and depth charges to protect merchant-ship convoys and battle fleets against submarine attack. In World War II, with the addition of radar and anti-aircraft guns, this escort role was expanded to include air defense.

Since 1945 the destroyer's dual anti-aircraft-antisubmarine role has continued through the transition to guided missiles. A modern destroyer's armament consists of surface-to-air missiles, antisubmarine torpedoes, antiship missiles, and one or two main guns of about four or five inches in calibre. Many destroyers carry submarine-hunting helicopters, and

USS Callaghan, guided missile destroyer of the Kidd class

Official U.S. Navy photograph

some carry cruise missiles. Modern destroyers range from 4,000 to 7,000 tons in displacement, are capable of speeds of more than 30 knots, and carry crews of about 300.

Destutt de Tracy, Antoine-Louis-Claude, Count (comte) (b. July 20, 1754, Bourbonnais, France—d. March 9, 1836, Paris), French philosopher, soldier, and chief *Idéologue*, so called for the philosophical school of *Idéologie*, which he founded.

Born into a noble family that originated in Scotland, Destutt de Tracy became colonel of the Penthievre regiment before being elected to the States General of 1789. He was promoted to brigadier early in 1792 but soon resigned his commission. He was imprisoned for nearly a year under the Reign of Terror during the French Revolution. An associate member of the French Institut National, he was also a member of the French Academy (1808), a senator during the reign of Napoleon I, and a peer after the restoration of the monarchy.

Destutt de Tracy coined the word *idéologie* (English: "ideology") in 1796 as a name for his own "science of ideas." Influenced by the work of John Locke, he presented his basic ideas in *Éléments d'idéologie*, 4 vol. (1801–15). Like the sensationalism of Étienne Bonnot de Condillac (1715–80), *Idéologie* stressed the importance of human sensations in the formation of knowledge. Destutt de Tracy, however, further refined Condillac's views to emphasize the physiological nature of sensation. Human thought, he asserted, is nothing but an elaboration of sensations, an activity of the nervous system. The four principal realms of conscious behaviour—perception, memory, judgment, and will—all employ various combinations of sensations. As a result of its extreme dependence on the human senses for verification of knowledge, *Idéologie* threatened not only religious doctrine but secular authority as well, and the movement was suppressed by Napoleon from 1803.

In addition to an unfinished treatise on the human will, *Traité de la volonté et de ses effets* (1805; "Treatise on the Will and Its Effects"), Destutt de Tracy's other writings include *Grammaire générale* (1803; "General Grammar") and *Logique* (1805; "Logic"). His *Commentaire sur l'esprit des lois de Montesquieu* (*Commentary and Review of Mon-*

tesquieu's Spirit of Laws), written in 1808, was translated and revised in 1811 by the American statesman Thomas Jefferson, with whom Destutt de Tracy corresponded.

DESY, byname of DEUTSCHES ELEKTRONEN-SYNCHROTRON, English GERMAN ELECTRON-SYNCHROTRON, the largest centre for particle-physics research in Germany, located in Hamburg. DESY is funded jointly by the German federal government and the city of Hamburg; in addition, scientists from other countries who participate in the experiments there donate equipment.

The laboratory was founded in 1959, when construction began on an electron synchrotron, which was completed in 1964 and eventually could generate an energy level of 7.4 billion electron-volts (GeV). The Double Ring Storage Facility (DORIS) was completed 10 years later and was capable of colliding beams of electrons and positrons at 3.5 GeV per beam; in 1978 its power was upgraded to 5 GeV per beam. DORIS is no longer used as a collider, but its electron beam provides synchrotron radiation (mainly at X-ray and ultraviolet wavelengths) for experiments on a variety of materials.

A larger collider capable of reaching 19 GeV per beam, the Positron-Electron Tandem Ring Accelerator (PETRA), began operation in 1978. Experiments with PETRA the following year gave the first direct evidence of the existence of gluons, the particles that carry the strong force between quarks. The laboratory's newest facility, completed in 1992, is the Hadron-Electron Ring Accelerator (HERA), the first machine capable of colliding electrons and protons. HERA consists of two rings in a single tunnel with a circumference of 6.3 km (3.9 miles); one ring accelerates electrons to 30 GeV and the other protons to 820 GeV. It is being used to continue the study of quarks.

(Ch.Su.)

detached retina, eye disorder involving separation of most layers of the retina, the light-sensitive layer of tissue that lines the back and sides of the eye, from the choroid, the pigmented middle layer of the eyeball. As a person ages, small tears can develop in the retina, through which vitreous humour (the jellylike substance in the eye) leaks. This causes the retina to peel away from the choroid. Retinal detachment usually occurs only in persons who are middle-aged or older (an exception is the disease retrolental fibroplasia, *q.v.*), and it is more common in individuals who are nearsighted. The detachment also may result from a physical accident. The separation usually develops slowly and does not cause pain. A person typically will describe seeing floating black spots and flashes of light in the affected eye, and vision will become progressively more blurred. Restoration of the retina to its normal position is achieved by draining the fluid from behind it and applying heat, a laser beam, or extreme cold to the wall of the eye. The resultant scar tissue that forms seals the tears and prevents the retina from detaching again. If the retina is not reattached soon enough, the affected eye becomes permanently blinded.

Detaille, Édouard, in full JEAN-BAPTISTE-ÉDOUARD DETAILLE (b. Oct. 5, 1848, Paris, France—d. Dec. 23, 1912, Paris), French painter known for his accurate portrayals of battles and military life.

Detaille studied with J.L.E. Meissonier and employed a technique of literal exactitude based on that of his master. Detaille developed a wide knowledge of military detail, making his work an important source for the study of late 19th-century military history; e.g., in 1883 he produced, with Alphonse de Neuville, a profusely illustrated two-volume work, *L'Armée française*. His paintings of the Franco-German War (e.g., "The Defense of

Champigny," 1879) made him famous. His most characteristic works, however, infused with legend and sentiment, are his pictures of Napoleon I and his armies. Detaille also painted some portraits and nonmilitary subjects and was a gifted actor.

detection, in electronics, the process of rectifying a radio wave and recovering any information superimposed on it; it is essentially the reverse of modulation (*q.v.*).

detective story, type of popular literature dealing with the step-by-step investigation and solution of a crime, usually murder.

The traditional elements of the detective story are: (1) the seemingly perfect crime; (2) the wrongly accused suspect at whom circumstantial evidence points; (3) the bungling of dim-witted police; (4) the greater powers of observation and superior mind of the detective; and (5) the startling and unexpected denouement, in which the detective reveals how the identity of the culprit was ascertained. Detective stories frequently operate on the principle that superficially convincing evidence is ultimately irrelevant. Usually it is also axiomatic that the clues from which a logical solution to the problem can be reached be fairly presented to the reader at exactly the same time that the sleuth receives them and that the sleuth deduce the solution to the puzzle from a logical interpretation of these clues.

The first detective story was "The Murders in the Rue Morgue" by Edgar Allan Poe, published in April 1841. The profession of detective had come into being only a few decades earlier, and Poe is generally thought to have been influenced by the *Mémoires* (1828–29) of François-Eugène Vidocq, who in 1817 founded the world's first detective bureau, in Paris. Poe's fictional French detective, C. Auguste Dupin, appeared in two other stories, "The Mystery of Marie Roget" (1845) and "The Purloined Letter" (1845). The detective story soon expanded to novel length.

The French author Emile Gaboriau's *L'Af-faire Lerouge* (1866) was an enormously successful novel that had several sequels. Wilkie Collins' *The Moonstone* (1868) remains one of the finest English detective novels. Anna Katharine Green became one of the first American detective novelists with *The Leavenworth Case* (1878). *The Mystery of a Hansom Cab* (1886) by the Australian Fergus Hume was a phenomenal commercial success.

The greatest of all fictional detectives, Sherlock Holmes, along with his loyal, somewhat obtuse companion Dr. Watson, made his first appearance in Arthur (later Sir Arthur) Conan Doyle's novel *A Study in Scarlet* (1887) and continued into the 20th century in such collections of stories as *The Memoirs of Sherlock Holmes* (1894) and the longer *Hound of the Baskervilles* (1902). So great was the appeal of Sherlock Holmes's detecting style that the death of Conan Doyle did little to end Holmes's career; several writers, often expanding upon circumstances mentioned in the original works, have attempted to carry on the Holmesian tradition.

The early years of the 20th century produced a number of distinguished detective novels, among them Mary Roberts Rinehart's *The Circular Staircase* (1908) and G.K. Chesterton's *The Innocence of Father Brown* (1911) and other novels with the clerical detective. From 1920 on, the names of many fictional detectives became household words: Inspector French, introduced in Freeman Wills Crofts's *The Cask* (1920); Hercule Poirot, in Agatha Christie's *The Mysterious Affair at Styles* (1920), and Miss Marple, in *Murder at the Vicarage* (1930); Lord Peter Wimsey, in Dorothy L. Sayers' *Whose Body?* (1923); Philo Vance, in S.S. Van Dine's *The Benson Murder Case* (1926); Albert Campion, in Margery Allingham's *The Crime at Black Dudley* (1929; also published as *The Black*

Dudley Murder); and Ellery Queen, conceived by Frederic Dannay and Manfred B. Lee, in *The Roman Hat Mystery* (1929).

In a sense, the 1930s was the golden age of the detective story, with the detectives named above continuing in new novels. The decade was also marked by the books of Dashiell Hammett, who drew upon his own experience as a private detective to produce both stories and novels, notably *The Maltese Falcon* (1930) featuring Sam Spade. In Hammett's work, the character of the detective became as important as the "whodunit" aspect of ratiocination was earlier. *The Thin Man* (1932), with Nick and Nora Charles, was more in the conventional vein, with the added fillip of detection by a witty married couple. Successors to Hammett included Raymond Chandler and Ross Macdonald, who also emphasized the characters of their tough but humane detectives Philip Marlowe and Lew Archer, respectively. At the end of the 1940s, Mickey Spillane preserved the hard-boiled crime fiction approach of Hammett and others, but his emphasis on sex and sadism became a formula that brought him amazing commercial success beginning with *I, the Jury* (1947).

The introduction of the mass-produced paperback book in the late 1930s made detective-story writers wealthy, among them the Americans Erle Stanley Gardner, whose criminal lawyer Perry Mason unraveled crimes in court; Rex Stout, with his fat, orchid-raising detective Nero Wolfe and his urbane assistant Archie Goodwin; and Frances and Richard Lockridge, with another bright married couple, Mr. and Mrs. North. In France, Georges Simenon produced novel after novel at a rapid-fire pace, making his hero, Inspector Maigret, one of the best-known detectives since Sherlock Holmes. Other writers who carried out the tradition of Holmes or broke new ground included Nicholas Blake (pseudonym of the poet C. Day-Lewis), Michael Innes, Dame Ngaio Marsh, Josephine Tey, Carter Dickson (John Dickson Carr), and P.D. James. After 1945, writers such as John Le Carré adapted the detective-story format to the increasingly popular spy novel.

The Mystery Writers of America, a professional organization founded in 1945 to elevate the standards of mystery writing, including the detective story, has exerted an important influence through its annual Edgar Allan Poe Awards for excellence. *See also* mystery story; hard-boiled fiction.

BIBLIOGRAPHY. Notable works on the detective story include Howard Haycraft, *Murder for Pleasure*, enlarged ed. (1968); and Jacques Barzun and Wendell H. Taylor, *Catalogue of Crime* (1971).

detention, preventive (law): *see* preventive detention.

detergent, any of various surface-active agents (surfactants) particularly effective in dislodging foreign matter from soiled surfaces and retaining it in suspension. The term usually denotes a synthetic substance that is not prepared by saponifying fats and oils (as is soap).

A brief treatment of detergents follows. For full treatment, *see* MACROPAEDIA: Industries, Chemical Process.

Dishwashing and laundering of clothing are the principal applications of detergents for which the liquid bath is water. Detergents also are used as emulsifiers in many applications. Detergents that function in nonaqueous media include dispersing agents added to lubricating oils used in automotive engines to prevent the accumulation of varnishlike deposits on the cylinder walls; to gasoline to prevent the buildup of gummy residues in the carburetor; and to dry-cleaning solvents to facilitate the removal of soil from garments. *See also* surface-active agent. *Compare* soap.

determinant, in genetics, the term used in the late 19th century by the German biologist

August Weismann to describe the component of hereditary material, or germ plasm, that specifies the characteristics of different cells.

determinant, in linear and multilinear algebra, a value, denoted $\det A$, associated with a square matrix A of n rows and n columns. Designating any element of the matrix by the symbol a_{rc} (the subscript r identifies the row and c the column), the determinant is evaluated by finding the sum of $n!$ terms, each of which is the product of the coefficient $(-1)^{r+c}$ and n elements, no two from the same row or column.

For the trivial case of $n = 1$, the value of the determinant is the value of the single element a_{11} . For $n = 2$, the matrix is

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$$

and the determinant is $a_{11}a_{22} - a_{12}a_{21}$.

Larger determinants ordinarily are evaluated by a stepwise process, expanding them into sums of terms, each the product of a coefficient and a smaller determinant. Any row or column of the matrix is selected, each of its elements a_{rc} is multiplied by the factor $(-1)^{r+c}$ and by the smaller determinant M_{rc} formed by deleting the r th row and c th column from the original array. Each of these products is expanded in the same way until the small determinants can be evaluated by inspection. At each stage, the process is facilitated by choosing the row or column containing the most zeros.

For example, the determinant of the matrix

$$A = \begin{bmatrix} 2 & 0 & 3 \\ 4 & 1 & -1 \\ 1 & 0 & 7 \end{bmatrix}$$

is most easily evaluated with respect to the second column:

$$\det A = 0 \cdot (-1)^3 M_{12} + 1 \cdot (-1)^4 M_{22} + 0 \cdot (-1)^5 M_{32} = M_{22} = (2 \cdot 7 - 3 \cdot 1) = 11.$$

determinism, in philosophy, theory that all events, including moral choices, are completely determined by previously existing causes that preclude free will and the possibility that humans could have acted otherwise. The theory holds that the universe is utterly rational because complete knowledge of any given situation assures that unerring knowledge of its future is also possible. Pierre-Simon, Marquis de Laplace, in the 18th century framed the classical formulation of this thesis. For him, the present state of the universe is the effect of its previous state and the cause of the state that follows it. If a mind, at any given moment, could know all of the forces operating in nature and the respective positions of all its components, it would thereby know with certainty the future and the past of every entity, large or small. The Persian poet Omar Khayyam expressed a similar deterministic view of the world in the concluding half of one of his quatrains: "And the first Morning of Creation wrote / What the Last Dawn of Reckoning shall read."

Indeterminism, on the other hand, though not denying the influence of behavioral patterns and certain extrinsic forces on human actions, insists on the reality of free choice. Exponents of determinism strive to defend their theory as compatible with moral responsibility by saying, for example, that evil results of certain actions can be foreseen, and this in itself imposes moral responsibility and creates a deterrent external cause that can influence actions.

deterrence, military strategy under which one power uses the threat of reprisal effectively to preclude an attack from an adversary power.

With the advent of nuclear weapons, the term deterrence largely has been applied to the basic strategy of the nuclear powers and of the major alliance systems. The premise of the strategy is that each nuclear power maintains a high level of instant and overwhelming destructive capability against any aggression—*i.e.*, the ability, visible and credible to a would-be attacker, to inflict unacceptable damage upon the attacker with forces that survive a surprise attack. An essential element in successful deterrence is a degree of uncertainty on the part of a would-be aggressor as to whether the target power, although attacked and badly damaged, will nonetheless retaliate—even at the risk of suffering further, crippling damage in a second attack. Thus, nuclear-deterrence strategy relies on two basic conditions: the ability to retaliate after a surprise attack must be perceived as credible; and the will to retaliate must be perceived as a possibility, though not necessarily as a certainty.

Detmold, *Regierungsbezirk* (administrative district), northeastern North Rhine–Westphalia *Land* (state), northwestern Germany. Detmold is bordered by Lower Saxony *Land* to the north and east, Hesse *Land* to the south-east, the *Regierungsbezirke* of Arnsberg to the southwest, and Münster to the west. It is co-extensive with the northeastern portion of the larger historic region of Westphalia (*q.v.*) and the small former German state of Lippe. The district was created in 1947 and takes its name from that of its administrative seat.

The level Münsterland lowland, an extension of the North German Plain, penetrates in a wide baylike formation into western Detmold between the Weserbergland, a hilly region bordering the Weser River, and the Sauerland plateau. The region's mixture of clay and sand soils and much rainfall support ideal pastures for livestock grazing. Gütersloh, the chief city of the Detmold lowland, has a diversified industrial structure; many surrounding towns specialize in furniture construction. The Senne region, located on the eastern fringe of the Münsterland, is covered by deposits of fluvial-glacial sand approximately 80 feet (25 m) thick, forming an extensive belt of heath vegetation. Paderborn, situated on this eastern fringe, serves as the marketing and export centre for the surrounding agricultural region.

The Weserbergland, comprising a number of independent ranges politically divided between Detmold and Lower Saxony, extends around the east and northeast sides of the Münsterland bay. The Detmold hills are characterized by several inward-facing escarpments and narrow elongated ridges, including those of the Teutoburg Forest (Teutoburger Wald) and Egge Mountains (Eggegebirge) curving southeast and the Wiehen Mountains (Wiehengebirge) in the north. The cities of Detmold and Bielefeld, the district's largest, lie on the north slope of the wooded Teutoburg Forest ridge. Bielefeld has a highly diversified industrial structure but is best known for its traditional linen industry. Situated between the escarpments is the Ravensberger Hügelland depression with the town of Herford in its centre. The depression is covered by fertile clay and marl soils and planted in sugar beets, wheat, and vegetables. The sandstone hills of the Lippe Bergland extend along the eastern border with Lower Saxony. Beech forests interspersed with cultivated fields and pastures supply local furniture and paper industries. North of the Wiehen Mountains, the Weserbergland is bordered by the North German Plain. There the Weser River leaves the hill country through the picturesque Porta Westfalica water gap near Minden. Numerous health spas are located in the Weserbergland.

The majority of the population of Detmold

Regierungsbezirk are descendants of the western Saxons and speak a Low German dialect. More than 65 percent of the people are Protestants and about 30 percent are Roman Catholics. The predominant rural settlement pattern is one of dispersed or loosely grouped farmsteads. Higher education in the district is centred at the University of Bielefeld and a university-level institution for advanced technical training at Paderborn. Area 2,516 square miles (6,517 square km). Pop. (1997 est.) 2,032,500.

Detmold, city, North Rhine–Westphalia *Land* (state), northwestern Germany, situated on the eastern slope of the Teutoburg Forest (Teutoburger Wald), on the Werre River. The capital, from the 12th century, of the former principality and *Land* of Lippe, it was chartered about 1350. Three miles (5 km) to the southwest, on the Grotenburg (mountain), 1,250 feet (381 m) high, stands Ernst von Bandel's colossal statue (188 feet [57 m] tall) of Arminius, or Hermann, the leader of the Cherusci who defeated the Romans there in AD 9. Detmold (then called Theotmalli) was also the scene of a conflict between the army of Charlemagne and the Saxons in 783.

A picturesque residential city with half-timbered buildings and tree-lined avenues, Detmold has two former residences of the princes of Lippe-Detmold: the Renaissance château (1550) and the New Palace (1708–18; enlarged 1850). The latter now houses the state museum and the North West German Academy of Music. Furniture making is the chief industry. Pop. (1998 est.) 73,820.

detonator: *see* blasting cap.

Detroit, city, seat of Wayne county, southeastern Michigan, U.S., on the Detroit River (connecting Lakes Erie and St. Clair), opposite Windsor, Ont., Can. It was founded in 1701 by a French trader, Antoine Lammé de la Mothe Cadillac, who built a fort on the river and named it Fort-Pontchartrain-du-Détroit in honour of his patron (the French word *détroit* meaning "strait"); later the British called it simply Detroit. In the 20th century the city's name became synonymous with the American automotive industry.

The city layout. Detroit is situated on a broad, generally flat plain. The downtown area retains vestiges of a hexagonal street pattern laid out early in the 19th century that largely disappeared as the city expanded. Many of the city's commercial and civic buildings are concentrated in the downtown area near the river and include the City-County Building, COBO Conference/Exhibition Center, COBO and Joe Louis arenas, and the Renaissance Center (1977), which includes a 73-story hotel. Many of the city's museums and the public library, however, are located about 3 miles (5 km) to the northwest in the Cultural Center. The city completely surrounds the communities of Hamtramck and Highland Park.

The people and economy. Detroit's population grew dramatically between 1850 and 1950. The city's industrial growth was a magnet for migrants, at first chiefly European immigrants and later blacks from the South. The population has declined steadily since the mid-1950s, however, in part because much of the white community moved to the suburbs and also because of the loss of industry. By 2000, more than three-fourths of the population was black.

Detroit has a diversified manufacturing and shipping base, but the city's economy remains highly sensitive to the fortunes of the automotive industry. In addition to motor vehicles and automotive parts, the city's factories produce steel, automation and assembly systems, welding systems, processed foods, metal and rubber products, paint, and chemicals; services have become increasingly important.

Roads dominate Detroit's transportation sys-

tem and make it a trucking centre. The city is connected to Windsor by a bridge and a tunnel. The Detroit River is heavily used by Great Lakes shipping, and the region's port facilities handle large quantities of raw materials. Detroit Metropolitan Wayne County Airport is located about 20 miles (30 km) southwest of downtown.

Cultural life. Among the colleges and universities in the city are Wayne State University (1868) and the University of Detroit Mercy (1877). Important cultural institutions include the Cranbrook Academy of Art and Cranbrook Institute of Science in suburban Bloomfield Hills, the Detroit Institute of Arts, the Detroit Science Center, the Detroit Historical Museum, and the Charles H. Wright Museum of African American History. The Henry Ford Museum and Greenfield Village in suburban Dearborn has dozens of historic buildings and a large museum including exhibits on the automobile and American manufacturing. The Detroit Zoo is in Royal Oak. Belle Isle Park, in the Detroit River, has a conservatory, a shipping museum, a zoo, and an aquarium. The city has a symphony orchestra, an opera company, and a sizable theatre district. Detroit's professional sports teams include the Tigers (baseball), Lions (football), Pistons (basketball), and Red Wings (hockey). The annual Ford Detroit International Jazz Festival is one of the largest music festivals in North America. Detroit is known for Motown, the recording company started there in 1959 by Berry Gordy, Jr., that was responsible for dozens of popular songs and artists in the 1960s. The two-story house where most of the music was recorded is preserved as a museum.

History. In the early 18th century Detroit became an important fur-trading post. In 1760, during the French and Indian War, it was surrendered to the British. The Ottawa under Chief Pontiac tried to capture the fort in 1763 but were defeated. The Jay Treaty (Nov. 19, 1794) provided for the evacuation of the British in the Northwest Territories, and in 1796 Detroit came under American control.

In 1805 Detroit became the capital of the newly created Michigan Territory. In that same year a fire destroyed the community, and the town had to be rebuilt. Soon after the outbreak of the War of 1812, Detroit was again surrendered to the British, but the Americans recaptured it in September 1813. In 1815 Detroit was incorporated as a city.

In 1818 the first steamboat on the upper Great Lakes began regular runs between Buffalo, N.Y., and Detroit. Grain and other agricultural produce poured into the city by rail and water for processing and forwarding to other parts of the nation or to Europe. Detroit became one of the flour-milling centres of the country. It was the capital of Michigan state from its creation in 1837 until 1847, when the capital was moved to Lansing.

Following the American Civil War, Detroit changed from its early role as a country merchant to that of industrial magnate. It became the automobile capital of the world with the help of the manufacturer Henry Ford, who introduced the assembly line in 1914. Detroit's industrial development accelerated during World Wars I and II, when it was an important producer of military armaments, and it attracted a large number of migrants, particularly blacks from the South. In 1943 fighting broke out between whites and blacks in the city. Other racial disturbances occurred in 1967 and caused extensive property damage and dozens of deaths.

The subsequent departure of many whites from the city and loss of jobs in the area's automotive industry brought economic hardship and social problems. By the 1970s, the downtown area was in severe decline. Redevelopment efforts along the riverfront had begun as early as the 1950s and continued throughout the rest of the 20th century, including the Re-

The Renaissance Center, Detroit, along the Detroit River

Colour Library International

naissance Center in the 1970s and the People Mover automated transit system in the 1980s. However, economic problems, a high crime rate, and continued movement of affluent, primarily white citizens to the suburbs in the 1980s and '90s made many of the revitalization efforts less successful than had been hoped.

Pop. (2000) city, 951,270; Detroit PMSA, 4,441,551; Detroit-Ann Arbor-Flint CMSA, 5,456,428.

Detroit Institute of Arts, art museum in Detroit, Mich., noted for its collection of American paintings from the 19th century and its Dutch, Flemish, and Italian paintings from the Renaissance through the Baroque periods. It is also known for a large collection of arts of antiquity and Islām. The Greek, Roman, Egyptian, and ancient Persian collections have been augmented by artifacts dating from Bronze Age western Europe, Mesopotamia, and ancient Arabia.

The museum was founded in 1885 by a group of Detroit citizens, given to the city in 1919, and moved into its present neoclassical structure in 1927. It was enlarged by additions in 1966 and 1971. The museum's central courtyard is decorated with a series of 27 murals by the Mexican painter Diego Rivera that depict the automobile industry.

Detroit River, river forming part of the boundary between Michigan, U.S. (west), and Ontario, Can. (east), and connecting Lake St. Clair (north) with the west end of Lake Erie (south). The river flows southwest and south for 32 miles (51 km) past Detroit and Windsor, Ont. It is crossed completely by a bridge and a tunnel and is 1 to 1.5 miles (1.5 to 2.5 km) wide. The largest islands in the river are Belle Isle (a city park of Detroit) and Grosse Ile (a residential area with an airport), both in Michigan, and Fighting Island in Ontario. The river is heavily used by both pleasure craft and Great Lakes shipping.

Detti Falls, Icelandic *DETTIFOSS*, waterfall, northeastern Iceland, on the island's second longest river, *Jökulsá á Fjöllum*. The Detti Falls have a vertical drop of 144 feet (44 m). It is the largest Icelandic waterfall in volume and has the greatest hydroelectric-power potential of any location in Iceland. Its scenic beauty and accessibility by road from Akureyri have made it a tourist attraction.

Deucalion, in Greek legend, the son of Prometheus (the creator of mankind), king of Phthia in Thessaly, and husband of Pyrrha; he was also the father of Hellen, the mythical ancestor of the Hellenic race.

When Zeus, the king of the gods, resolved to destroy all humanity by a flood, Deucalion constructed an ark in which, according to one version, he and his wife rode out the flood and landed on Mount Parnassus. Offering sacrifice and inquiring how to renew the human race, they were ordered to cast behind them the bones of their mother. The couple correctly interpreted this to mean they should throw behind them the stones of the hillsides ("mother earth"), and did so. Those stones thrown by Deucalion became men, while those thrown by Pyrrha became women.

Deulino, Truce of (December 1618), agreement suspending for 14½ years the hostilities between Poland and Russia that resulted from Polish intervention in Russia during the Time of Troubles (1606–13). In 1609, during the unstable reign (1606–10) of the Russian tsar Vasily Shuysky, the Polish king Sigismund III declared war on Muscovy. His army laid siege to Smolensk (September 1609), and Sigismund tried to place his son Wladyslaw on the Muscovite throne.

In August 1610 the leading Muscovite boyars accepted Wladyslaw and opened their city's gates to the Polish troops; but Sigismund, deciding that he wanted the Russian throne for himself, resumed the war against Muscovy. His troops burned much of Moscow and occupied Smolensk. Nevertheless, a Russian army captured Moscow, and a *zemsky sobor* ("assembly of the land") named Michael Romanov the new tsar (1613). Wladyslaw then launched a new campaign against Russia (1617–18). The Truce of Deulino, which concluded Wladyslaw's campaign, placed Smolensk, as well as other conquered western Russian territories, in Poland's possession. When the truce expired (1632), hostilities were resumed. The Russians, however, failed to regain Smolensk and accepted the Treaty of Polanowo, or Polyanov (1634). The Russians had to pay 20,000 rubles to the Poles, but Wladyslaw recognized Michael as the legitimate tsar of Russia.

Deus (Nogueira Ramos), João de (b. March 8, 1830, São Bartolomeu de Messines, Algarve, Port.—d. Jan. 11, 1896, Lisbon), lyric poet who fashioned a simple and expressive language that revitalized Portuguese Romantic poetry. He was a major influence on Portuguese literature of the early 20th century.

As a student at Coimbra, Deus led a bohemian life and spent much time composing poems that he read aloud to his friends. Many of his lyrics were salvaged by his friends and printed in reviews. He graduated in the faculty of law in 1859 after taking 10 years to complete a 5-year course, but he remained in Coimbra until 1862, an influential figure among the younger poets who were to break with the literary for-

malism of the period. Though his first collection of poems, *Flores do Campo* (1868; "Wild-flowers"), was well received, he was constantly in financial difficulties. His friends succeeded in having him elected to Parliament in 1869, but he renounced his office over a question of principle, a gesture that brought him great popularity but little material comfort. After his marriage he was forced to eke out a living by composing verses on commission for tradesmen and by doing menial jobs. During this period he devoted himself to developing a new method of teaching reading. His second volume of verse, *Fôlhas Sôltas* ("Loose Leaves"), and *Cartilha Maternal* ("Maternal Primer") both appeared in 1876. His reading method was officially adopted in 1888, and he was appointed to introduce it. He was by that time a famous man. His collected works, *Campo de Flores* ("Field of Flowers"), were published in 1893; two years later he was publicly proclaimed the greatest Portuguese poet of his generation.

deus ex machina (Latin: "god from the machine"), in ancient Greek and Roman drama, the timely appearance of a god to unravel and resolve the plot. The *deus ex machina* was named for the convention of the god appearing in the sky, an effect achieved by means of a crane (Greek: *mēchanē*). The dramatic device dates from the 5th century BC; a god appears in Sophocles' *Philoctetes* and in most of the plays of Euripides to solve a crisis.

Since ancient times, the phrase has also been applied to an unexpected saviour, or to an improbable event that brings order out of chaos (e.g., the arrival, in time to avert tragedy, of the U.S. cavalry in a western film).

deus otiosus (Latin: "neutral god," or "hidden god"), in the history of religions and philosophy, a high god who has withdrawn from the immediate details of the governing of the world. The god has delegated all work on Earth to ancestors or nature spirits, who act as mediators between the god and humans. This concept of god occurs widely in Africa, Melanesia, and South America. In Western philosophy, the *deus otiosus* concept has been attributed to deism, a 17th–18th-century Western rationalistic religio-philosophical movement, in its view of a nonintervening creator of the universe. Although this stark interpretation was accepted by very few deists during the period in which they flourished, many of their antagonists attempted to force them into the position of stating that after the original act of creation God virtually withdrew and refrained from interfering in the processes of nature and human affairs.

Deuseddit, SAINT, also called **DEUSEDIT I**, or **ADEODATUS I** (b. Rome [Italy]—d. Nov. 8, 618, Rome; feast day November 8), pope from 615 to 618. His pontificate is chiefly noteworthy for an unsuccessful resumption of the Byzantine war against the Lombards in Italy and for a reversal of the policy of popes Gregory I and Boniface IV, who favoured monks over the secular clergy.

deuterium (D, or ²H), also called **HEAVY HYDROGEN**, isotope of hydrogen with atomic weight of approximately 2. Its nucleus, consisting of one proton and one neutron, has double the mass of the nucleus of ordinary hydrogen. Deuterium is a stable atomic species found in natural hydrogen compounds to the extent of 0.014 to 0.015 percent.

Deuterium was discovered (1931) by the American chemist Harold C. Urey (for which he was awarded the Nobel Prize for Chemistry in 1934) and his associates F.G. Brickwedde and G.M. Murphy. Urey predicted a difference between the vapour pressures of molecular hydrogen (H₂) and of a corresponding

molecule with one hydrogen atom replaced by deuterium (HD) and, thus, the possibility of separating these substances by distillation of liquid hydrogen. The deuterium was detected (by its atomic spectrum) in the residue of a distillation of liquid hydrogen. Deuterium was first prepared in pure form in 1933 by G.N. Lewis, using the electrolytic method of concentration discovered by E.W. Washburn. When water is electrolyzed—*i.e.*, decomposed by an electric current (actually a water solution of an electrolyte, usually sodium hydroxide, is used)—the hydrogen gas produced contains a smaller fraction of deuterium than the remaining water, and, hence, deuterium is concentrated in the water. Very nearly pure deuterium oxide (D₂O; heavy water) is secured when the amount of water has been reduced to about one hundred-thousandth of its original volume by continued electrolysis. This was the standard method of preparation of D₂O before World War II.

Deuterium enters into all chemical reactions characteristic of ordinary hydrogen, forming equivalent compounds. Deuterium, however, reacts more slowly than ordinary hydrogen, a criterion that distinguishes the two forms of hydrogen. Because of this property, among others, deuterium is extensively used as an isotopic tracer in investigations of chemical and biochemical reactions involving hydrogen.

The nuclear fusion of deuterium atoms or of deuterium and the heavier hydrogen isotope,

Comparison of the physical properties of molecular forms of hydrogen

tritium, at high temperature is accompanied by release of an enormous amount of energy; such reactions have been used in thermonuclear weapons. Since 1953, the stable solid substance lithium deuteride (LiD) has been used in place of both deuterium and tritium.

The physical properties of the molecular form of the isotope deuterium (D₂) and the molecules of hydrogen deuteride (HD) are compared with those of the molecules of ordinary hydrogen (H₂) in the Table.

deuterium oxide: *see* heavy water.

Deutero-Isaiah, also called SECOND ISAIAH, section of the Old Testament Book of Isaiah (chapters 40–55) that is later in origin than the preceding chapters, though not as late as the following chapters. *See* Isaiah, Book of.

deuterocanonical books, biblical literature accepted in the Roman canon but treated as apocryphal by Jewish and Protestant canons; also, an authentic biblical work added to the canon later. *See* apocrypha.

Deuteromycetes, also called FUNGI IMPERFECTI, artificial assemblage, or form-class, of fungi (kingdom Mycota) in which a true sexual state is uncommon or unknown. Many of these fungi reproduce asexually by spores (conidia or oidia) or by budding. Conidial stages are similar to those in the class Ascomycetes, but those of some species show affinities to lower (primitive) fungi and the class Basidiomycetes.

The Deuteromycetes form-class is divided into four form-orders based on the presence or absence of fruiting bodies, which contain the spores: Sphaeropsidales, conidia borne in a pycnidium (a flask-shaped fruiting body); Melanconiales, conidia borne in an acervulus (a cushionlike fruiting body); Moniliales, conidia not borne in a fruiting body; and Mycelia Sterilia, no conidia produced.

Many members are of great economic importance, some causing serious diseases of plants—anthracnose, botrytis blight, and wilt (*qq.v.*)—and of animals, including humans—aspergillosis, candidiasis, and ringworm (*qq.v.*). Molds of the genus *Penicillium* (*q.v.*) are of great therapeutic importance.

deuteron, nucleus of deuterium (heavy hydrogen) that consists of one proton and one neutron. Deuterons are formed chiefly by ionizing deuterium (stripping the single electron away from the atom) and are used as projectiles to produce nuclear reactions after accumulating high energies in particle accelerators. A deuteron also results from the capture of a slow neutron by a proton, accompanied by the emission of a gamma photon.

Deuteronomic Reform, great religious reformation instituted in the reign of King Josiah of Judah (c. 640–609 BC). It was so called because the book of the Law found in the Temple of Jerusalem (c. 622 BC), which was the basis of the reform, is considered by scholars to be the same as the law code in the book of Deuteronomy (chapters 12–26). The reform consisted of removing pagan altars and idols from the Temple, destroying rural sanctuaries and fertility cults, and centralizing worship at the Temple of Jerusalem.

Deuteronomist (D), one of the supposed sources of a portion of the Hebrew canon known as the Pentateuch, in particular, the source of the book of Deuteronomy, as well as of Joshua, Judges, Samuel, and Kings. (The other sources are the Yahwist [J], the Elohist [E], and the Priestly code [P].) D uses a distinctive vocabulary and style of exhortation to call for Israel's conformity with Yahweh's Covenant laws and to stress Yahweh's election of Israel as his special people.

Deuteronomy, Hebrew DEVARIM ("Words"), fifth book of the Old Testament, written in the form of a farewell address by Moses to the Israelites before they entered the Promised Land of Canaan. The speeches that constitute this address recall Israel's past, reiterate laws that Moses had communicated to the people at Horeb (Sinai), and emphasize that observance of these laws is essential for the well-being of the people in the land they are about to possess. The title Deuteronomy, derived from Greek, thus means a "copy," or a "repetition," of the law rather than "second law," as the word's etymology seems to suggest.

Although Deuteronomy is presented as an address by Moses, scholars generally agree that it dates from a much later period of Israelite history. An early edition of Deuteronomy as it exists today has been identified with the book of the Law discovered in the Temple of Jerusalem about 622 BC (2 Kings 22:8; 2 Chronicles 34:15). This early edition, corresponding roughly to chapters 5–26 and 28 of Deuteronomy as it now stands, expresses a cultic liturgy. Chapters 5–11 contain an introductory speech by Moses, largely hortatory. In chapters 12–26 laws are reiterated that the people are exhorted to obey. The section closes with a report of the formulation of a Covenant between God and his chosen people. Chapter 28 recounts in elaborate detail the blessings or curses that will come upon the people, depending on their response to laws that explicate their covenantal obligations. This arrangement of materials corresponds to the liturgy of Covenant renewal festivals that were celebrated in Israel's premonarchic pe-

riod. Within this cultic context very ancient laws were preserved and transmitted.

To this original core of materials other materials were added by interested parties in the years following the reforms instituted by King Josiah (reigned c. 640–609 BC). The final form is due to the work of a historian who added, among other things, a second introduction (chapters 1–4) and made Deuteronomy the book of first principles for his history of the Israelite people in the land of Canaan. Deuteronomy might thus be viewed as the first part of the history that follows, rather than as the last book of the Pentateuch, the generally accepted order most scholars prefer.

The principles governing the Deuteronomic historian's presentation of Israel's history are set forth in the book of Deuteronomy: faithfulness to Yahweh and obedience to his commands bring blessings; the worship of foreign gods and negligence of Yahweh's statutes bring a curse; Yahweh can be worshipped in only one sacred place (Jerusalem) by all Israel; priests, prophets, and kings are subject to Yahweh's law granted through Moses. Thus, the attribution of Deuteronomy to Moses tends to place Israel in an advanced stage of its history—when kings and a centralized cult were contemporary concerns—under the requirements of renewed ancient traditions.

Deuterostomia (Greek: "second mouth"), group of animals—including those of the phyla Echinodermata (*e.g.*, starfish, sea urchins), Chordata (*e.g.*, vertebrates), Chaetognatha (*e.g.*, arrowworms), and Brachiopoda (*e.g.*, lamp shells)—classified together on the basis of embryological development. During that process the mouth of the Deuterostomia develops from an opening into the embryonic gut other than the blastopore, which develops into the anus. The coelom (body cavity) develops from buds off the embryonic gut. A number of Deuterostomia have larval forms. The Deuterostomia constitute one of two divisions of the coelomates (animals having a coelom). *Compare* Protostomia.

Deutsche Angestellten-Gewerkschaft (DAG), English GERMAN SALARIED EMPLOYEES' UNION, white-collar labour organization in Germany. The DAG was organized in 1945, shortly after the end of World War II, and became established throughout West Germany; after 1990, workers joined from the former East Germany. The original belief was that white-collar workers should have a single organization separate from blue-collar workers. Several unsuccessful attempts were made, however, to integrate the DAG with the Deutscher Gewerkschaftsbund, Germany's largest labour federation. In the early 1990s the DAG had about 580,000 members.

Deutsche Bahn AG, English GERMAN RAILWAY, the railway system of Germany created in 1994 by the merger of the Deutsche Bundesbahn (German Federal Railway), the state rail system in the former West Germany, with the Deutsche Reichsbahn (German State Railway), the state system in the former East Germany. At the time of German reunification, the system route length totaled about 25,800 miles (41,500 km), of which two-thirds was in western Germany; about one-third of the track was electrified.

The first rail line in Germany was opened between Nürnberg and Fürth in 1835, and within a century the country had some 35,000 miles (56,000 km) of track. After 1870 the German states began transferring the privately owned railroads to public ownership. By 1920 the entire network was operated by one national rail corporation, the Reichsbahn. The division of Germany after World War II left the two successor states with a network that

was severely damaged in the war and largely had to be rebuilt and reequipped. In addition, much of the former east-west orientation was interrupted, and, especially in the west, the lines had to be realigned north-south. Since 1990, work has been underway to reestablish east-west links. The system also was converted to a quasi-state corporation in 1994.

Deutsche Bank AG, German banking house founded in 1870 in Berlin and headquartered since 1957 in Frankfurt am Main. The largest bank in the country, it operates more than 1,200 branches in Germany. It also has a number of foreign offices and has acquired controlling interests in several foreign banks in Europe, North and South America, and Australia.

The first bank was licensed by King William I of Prussia on March 10, 1870, and began operation in Berlin on April 9. Branches were opened in Bremen in 1871, in Hamburg, Shanghai, and Yokohama in 1872, and in London in 1873. By the end of the century it had absorbed a number of other German banks and multiplied its capital about tenfold, under its managing director Georg von Siemens. Expansion continued in the 20th century, and more mergers were capped in 1929 by the amalgamation of Deutsche Bank with its older rival, DiscontoGesellschaft. After experiencing difficulties at the onset of the Great Depression, the company prospered hugely under the Nazi regime.

With the collapse of the Third Reich, Deutsche Bank's offices in Berlin and eastern Germany were closed by the Russians or were expropriated; branches in western Germany were "decartelized," coalescing in 1947-48 as 10 independent banks. As the Cold War progressed and as the economic growth and cooperation of what by then was West Germany became more eagerly sought, however, NATO opposition to West German economic consolidation lessened. By 1952 the 10 banks had been reduced to 3; and in 1957 the 3 successor institutions were reunited to form a single Deutsche Bank AG.

Deutsche Bibliothek, Die, English THE GERMAN LIBRARY, the national library of Germany. It was created by the merger (1990) of the Deutsche Bibliothek (founded 1947) in Frankfurt am Main and the Deutsche Bücherei (1912) in Leipzig, which until the reunification of Germany had functioned as the national libraries of West and East Germany, respectively. The system also includes the Deutsche Musikarchiv (German Music Archive) in Berlin. The library is the depository for all books published in Germany and collects German books published abroad, translations of German books, and literature dealing with Germany and Germans. It issues the national bibliography (Deutsche Nationalbibliographie). The combined holdings exceed 13,000,000 volumes.

deutsche Blumen, English GERMAN FLOWERS, in pottery, floral decoration consisting of naturalistically painted "German" (i.e., European) flowers appearing individually or in

bouquets. Although Viennese potters had produced a type of naturalistic floral decoration about 1730, *deutsche Blumen* became popular only after they had appeared on Meissen porcelain, produced from about 1740. The flowers used to decorate the porcelain were at first copied from contemporary natural history books or engravings, but by about 1750 they were being studied from nature and appeared less stiff in presentation. The widely imitated style spread after the mid-18th century to such centres as Höchst, Frankenthal, and Berlin in Germany and to Chelsea, Bow, and Worcester in England.

Deutscher Gewerkschaftsbund (DGB), English GERMAN TRADE UNION FEDERATION, dominant union organization in Germany. The DGB was founded in Munich in 1949 and soon became the largest labour organization in West Germany, with 16 constituent unions; with the reunification of Germany in 1990, workers of the former East Germany were incorporated into the DGB.

The DGB is primarily a blue-collar organization, but it also includes a large number of white-collar workers and civil servants. It has avoided ties with political parties, although on policy issues it has tended to support the Social Democrats. In 1991 the federation had a total membership of about 11,800,000 workers (including about 3,800,000 workers from eastern Germany), which constituted about one-third of the total German workforce.

Deutscher Werkbund, English GERMAN ASSOCIATION OF CRAFTSMEN, the first organization of artists influential in its attempts to inspire good design and craftsmanship for mass-produced goods and architecture. The Werkbund, which was founded in Munich in 1907, was composed of artists, artisans, and architects who designed industrial, commercial, and household products as well as practicing architecture.

The group's intellectual leaders, architects Hermann Muthesius and Henry van de Velde, were influenced by William Morris, who, as leader of the 19th-century English Arts and Crafts Movement, proposed that industrial crafts be revived as a collaborative enterprise of designers and craftsmen. Van de Velde and Muthesius expanded Morris' ideas to include machine-made goods. They also proposed that form be determined only by function and that ornamentation be eliminated.

Soon after the Werkbund was founded, it divided into two factions. One, championed by Muthesius, advocated the greatest possible use of mechanical mass production and standardized design. The other faction, headed by van de Velde, maintained the value of individual artistic expression. The Werkbund adopted Muthesius' ideas in 1914.

The Werkbund exerted an immediate influence, and similar organizations soon grew up in Austria (Österreichischer Werkbund, 1912) and in Switzerland (Schweizerischer Werkbund, 1913). Sweden's Slöjdföreningen was converted to the approach by 1915, and England's Design and Industries Association (1915) also was modeled on the Deutscher Werkbund.

The Werkbund's influence was further enhanced by its exhibition of industrial art and architecture in Cologne (1914). Among the buildings exhibited were some of the most notable examples of modern architecture in steel, concrete, and glass. These included a theatre by van de Velde and an administrative office building, the Pavilion for Deutz Machinery Factory, and garages by the architect Walter Gropius.

World War I interrupted the Werkbund's activity, but after the war it reasserted itself with a significant exhibition in Stuttgart (1927). Organized by the German architect Ludwig Mies van der Rohe, the exhibition formed a compendium of contemporary European de-

velopments in domestic architecture and construction. Many of the exhibiting architects, such as Mies, Gropius, and Le Corbusier, followed the ideas of Muthesius and employed a high degree of standardization of materials and design, making it possible to build housing units inexpensively on a large scale.

The Werkbund also participated in the Paris exhibition of industrial arts and building held in 1930. Organized by Gropius, along with László Moholy-Nagy, Marcel Breuer, and Herbert Bayer, the Werkbund's displays successfully reemphasized the value of mass-produced housing units achieved through standardization of materials and design.

The Werkbund was disbanded in 1933 with the advent of Nazi rule in Germany. It was revived, however, after World War II.

Deutsches Elektronen-Synchrotron (German research centre): see DESY.

Deutsches Museum, in full DEUTSCHES MUSEUM VON MEISTERWERKEN DER NATURWISSENSCHAFT UND TECHNIK, English GERMAN MUSEUM OF MASTERPIECES OF NATURAL SCIENCE AND TECHNOLOGY, museum of science and industry established in Munich in 1903 and opened in 1925. Its pattern of organization and administration became the model for such later foundations as the Museum of Science and Industry in Chicago.

The Deutsches Museum owed its existence to the perseverance and initiative of Oskar von Miller, who convinced industry and government authorities of the usefulness of his idea and built up the museum over a period of two decades. Many of its valuable collections in the history of technology and in the physical sciences were destroyed during World War II, but they were later replaced.

Consult the INDEX first

Deutsches Theater, English GERMAN THEATRE, private dramatic society founded in Berlin in 1883 by the dramatist Adolf L'Arronge in reaction to an outmoded theatrical tradition. It presented plays in the ensemble style of the influential Meiningen Company. In 1894 it was affiliated with the Freie Bühne under Otto Brahm, who promoted the new naturalistic style of production. The company experienced another revival under the direction of Max Reinhardt from 1905 and again during the 1920s with Bertolt Brecht. The society was disbanded after World War I but was later revived under Heinz Hilpert, who was acting there and who had succeeded Reinhardt in 1937. Hilpert directed there into the 1950s as well as at the Deutsches Theatre at Göttingen.

Deutsches Wörterbuch, English GERMAN DICTIONARY, the first German dictionary conceived on scientific lines; initiated by Jacob and Wilhelm Grimm. The dictionary was designed to give the etymology and history, illustrated by quotations, of all the words in the (New) High German literary language from the time of Martin Luther (c. 1500) to that of J.W. von Goethe (d. 1832), as well as significant dialectal words and forms; pronunciations were to be omitted. The Grimm brothers completed four volumes of the massive projected work, Jacob being responsible for volumes I (published at Leipzig in 1852), III, and IV up to the word *Frucht* ("fruit") and Wilhelm for volume II. Other German philologists, essentially agreeing with the aims and principles established by the Grimms, continued to labour on the dictionary after the death of the brothers. Cooperation between scholars from East and West Germany expedited its completion (1960).

Deutschland: see Germany.

Deutschlandlied (German: "Song of Germany"), formerly (1922–45) **DEUTSCHLAND, DEUTSCHLAND ÜBER ALLES** ("Germany, Germany above all"), national anthem of Germany from 1922 to 1945, of West Germany from 1950 to 1990, and of unified Germany from 1990. The verses were written in 1848 by the nationalist poet and university professor August Heinrich Hoffmann von Fallersleben and were sung to a tune originally composed by Joseph Haydn in 1797 as an Austrian imperial anthem. (The tune appears in his *Emperor Quartet*, Opus 76, No. 3, and was used as an Austrian anthem for more than a century.) On Aug. 11, 1922, the Weimar Republic adopted the song and its first verse as the German national anthem:

Deutschland, Deutschland über Alles,
über Alles in der Welt,
Wenn es stets zu Schutz und Trutze
brüderlich zusammen hält,
Von der Maas bis an die Memel,
von der Etsch bis an den [Little] Belt,
Deutschland, Deutschland über Alles,
über Alles in der Welt!

Germany, Germany above all,
above all else in the world,
When it steadfastly holds together,
offensively and defensively,
with brotherhood,
From the Maas to the Memel,
from the Etsch to the [Little] Belt,
Germany, Germany above all,
above all else in the world.

It was retained as the anthem of Nazi Germany, along with the party anthem, the Horst Wessel Song. However, during the Nazi Era these lyrics took on unfortunate connotations. What was originally intended in 1848 as a call to place the concept of a unified nation above regional differences—with geographic borders marking the extent to which culturally German settlers had spread—became reinterpreted as a justification for German expansionism and misinterpreted by some as a claim to German world hegemony. For this reason, it was dropped for a while after World War II but then restored in 1950 by West Germany, using officially the third verse:

Einigkeit und Recht und Freiheit
für das deutsche Vaterland!
Danach lasst uns alle streben
brüderlich mit Herz und Hand!
Einigkeit und Recht und Freiheit
sind des Glückes Unterpfand.
Blüh im Glanze dieses Glückes,
blühe deutsches Vaterland!

Unity and rights and freedom
for the German fatherland.
Let us strive for it together,
brotherly with heart and hand.
Unity and rights and freedom
are the basis of good fortune.
Flower in the light of this good fortune,
flower German fatherland.

Deutschnationale Volkspartei: see German National People's Party.

Deux-Sèvres, département, Poitou-Charentes region, western France, separated from the Bay of Biscay to the west by Vendée *département* and to the southwest by the Charente-Maritime *département*. It is divided into the *arrondissements* of Niort, Parthenay, and Bressuire and is in the educational division of Poitiers. Created mainly from the historic province of Poitou but also including small portions of Aunis, Saintonge, and Angoumois, it has an area of 2,318 sq mi (6,004 sq km). In the shape of an upright rectangle, it is named after two rivers—Sèvre Niortaise and Sèvre Nantaise—which flow through it. The Sèvre Niortaise, in the southern half, flows west-

The Thouet River at Thouars, *département* of Deux-Sèvres, France

Danese—Rapho/Photo Researchers

ward through Niort, the capital. The Sèvre Nantaise rises in the north central part of the *département* and flows along the northwest border, ultimately joining the Loire at Nantes. The Thouet, another tributary of the Loire, flows northward through the medieval town of Thouars.

The *département*, which is almost entirely agricultural, has only small market towns and is an area of rural exodus. It has mild winters and warm summers, with more than 200 days of rain a year. Cattle raising predominates in the tree-bordered fields of the hilly north, and there is cultivation of cereal grains in the south. Woodlands abound in the east and on the southern border. The fertile reclaimed marshlands of the Marais Poitevin extend from the west to Niort.

Parthenay and Thouars, like Niort, are among the oldest towns in France. Saint-Maixent-l'École has a celebrated military school. The town of Melle is the centre of a region in which donkeys are bred. There is some industry at Niort. Pop. (1982) 342,812.

deva (Sanskrit: "divine"), Iranian **DAEVA**, in Vedic India, one of many divine powers, roughly divided on the basis of their identification with the forces of nature into sky, air, and earth divinities (e.g., Varuṇa, Indra, Soma). In the later monotheistic systems the *devas* became subordinate to the one supreme being. During the Vedic period the gods were divided into two classes, the *devas* and the *asuras* (in Iranian, *daevas* and *ahuras*). In India the *devas* came to be more powerful than the *asuras*, and the latter word eventually took on the meaning of demon. In Iran the reverse took place, and the *daevas* were denounced as demons by Zoroaster. They still survive as such in the *divs* of Persian folklore, especially through Ferdowsi's epic, *Shāh-nāmeḥ* (1010; "Book of Kings"). See also *asura*.

Deva, city, capital of Hunedoara *județ* (district), west central Romania, on the banks of the Mureș River, at an elevation of 590 ft (180 m). The town is dominated by Citadel Hill (1,217 ft), shaped like a truncated cone, which affords a commanding view of the Mureș Valley. Atop the hill are the ruins of a citadel, built in the 13th century at the time of the Mongol invasions. The city grew in the protective shadow of the citadel during the 13th and 14th centuries, but an explosion of an arsenal in the early 19th century destroyed the structure. At the foot of the hill rises Bethlen Castle, also known as Magna Curia, built in 1621; it now houses the regional museum. Deva has little industry, but there is some food processing, and nearby are small copper and andesite mines. Pop. (1982 est.) 72,362.

Devadāsi (Sanskrit: Handmaiden of the God), caste of women connected originally with great temples in southern India, where they dedicated themselves to the service of each temple's patron god.

The caste appears to date from the 9th and 10th centuries, the great period of temple

building in South India. The women attended the god—fanned the icon, honoured it with lights, and sang and danced for the god's amusement. They played an important part in preserving the cultural heritage. Their sons and daughters had equal rights of inheritance, an unusual practice among Hindu castes. Until the 20th century they were quite visible; in about 1800 the main temple of Kāñchipuram (Conjeeveram) had 100 Devadāsīs. As their occupation also involved temple prostitution, they came to be held in low social regard, and the caste—and its occupations—has begun to disappear.

Devadatta (fl. 6th century BC, India), Buddhist monk who sought to reform the *saṅgha* (the Buddhist monastic community) by imposing upon it a stricter code of life. He was a cousin of the Buddha.

Devadatta is said to have joined the *saṅgha* along with Ananda, who was possibly his brother, in the 20th year of Gautama's ministry. Fifteen years later, strengthened by his friendship with the Crown Prince of Magadha, Ajātaśatru, Devadatta proposed formally at a meeting of the *saṅgha* that the Buddha retire and hand over the leadership to him. This proposal was rejected, and Devadatta is said to have successfully instigated Ajātaśatru to execute Bimbisāra, his aged father, the King of Magadha, and to have made three abortive attempts to bring about the death of the Buddha—by hiring assassins, by rolling a rock off a mountainside at him, and by arranging for a mad elephant to be let loose in the road at the time of the collection of alms.

Sensing popular approval, Devadatta proposed stricter ascetic rules for the *saṅgha*. When these were refused, he persuaded some 500 of the Buddha's followers to join in a secession. Nothing further is known about Devadatta's movement, but it may possibly be referred to under the name of the Gotamakās in the *Anguttara Nikāya* (a canonical text), for Devadatta's family name was Gotama (Gautama). The Chinese pilgrim Hsüan-tsang recorded that in the 7th century monks of a monastery in Bengal were following a certain regulation of Devadatta's.

Devagiri (village, India): see Daulatābād.

devaluation, reduction in the exchange value of a country's monetary unit in terms of gold, silver, or foreign monetary units. Devaluation is employed to eliminate persistent balance-of-payments deficits, because devaluation has the effect of decreasing prices of the home country's exports in terms of the importer's currency and, at the same time, increasing prices of imports to home country buyers. If the demand for both exports and imports is relatively elastic (if the quantity purchased is more than proportionately responsive to changes in price), the nation's income from exports will rise, and its expenditure for imports will fall. Thus, its trade will be more in balance and its balance of payments improved.

An additional benefit may arise if the increase in exports results in a general expansion of the economy with an increase in the interest rate unaccompanied by an expansionary monetary policy. In that case, capital inflows will increase and outflows decrease. Devaluation will not be effective if the balance-of-payments disequilibrium is a result of basic structural faults in a nation's economy.

Revaluation, on the other hand, involves an increase in the exchange value of a country's monetary unit in terms of gold, silver, or foreign monetary units. It may be undertaken when a country's currency has been undervalued in comparison with others, causing persistent balance-of-payments surpluses.

Devanāgarī, also called **NĀGARĪ**, Indian script used to write the Sanskrit, Prakrit, Hindi, and Marathi languages, developed from the North

Indian monumental script known as Gupta and ultimately from the Brāhmī alphabet, from which all modern Indian writing systems are derived. In use from the 7th century AD and occurring in its mature form from the 11th century onward, Devanāgarī is characterized by long, horizontal strokes at the tops of the letters, usually joined in modern usage to form a continuous horizontal line through the script when written. Devanāgarī is written from left to right and uses 48 letters—34 consonants and 14 vowels and diphthongs. In practice, the script—though alphabetic in origin—is syllabic, with a short *a* sound being understood after each consonant unless the sign for an alternative vowel is used; in the past, Devanāgarī was frequently written without the vowel signs, sometimes resulting in confusion.

devarāja, in ancient Cambodia, the cult of the "god-king" established early in the 9th century AD by Jayavarman II, founder of the Khmer empire of Angkor. For centuries, the cult provided the religious basis of the royal authority of the Khmer kings.

The *devarāja* cult grew out of both Hindu and indigenous traditions. It taught that the king was a divine universal ruler, a manifestation of the Hindu god Śiva, whose divine essence was represented by the *linga* (or *lingam*), a phallic idol housed in a special mountain temple.

The king was deified in an elaborate and mystical ceremony, requiring a high priest, in which the divine essence of kingship was conferred on the ruler through the agency of the *linga*. The safeguarding of the *linga* became bound up with the security of the kingdom, and the great temple architecture of the Khmer period attests to the importance attached to the belief.

Devawongse Varoprakar, Prince (b. Nov. 27, 1858, Bangkok, Siam [now Thailand]—d. June 28, 1923, Bangkok), foreign minister of Siam from 1885 to 1923, whose policies enabled the kingdom to survive as an independent state.

The 42nd child of King Mongkut, Devawongse was the younger half brother of King Chulalongkorn. After only a smattering of formal Thai and English education in schools, his half brother organized in the early 1870s, he began his government career in the king's personal secretariat. He demonstrated a natural flair for foreign affairs, and Chulalongkorn named him foreign minister in 1885. Devawongse then established Siam's first modern bureaucratic ministry, with a Western-style system of organization.

The chief characteristics of Devawongse's foreign policy were genial accommodation and a determination that Siam should be treated as an equal by the Western countries with which the kingdom earlier had signed unequal treaties. He was able to escape the most aggressive imperialist pressures only by conceding large tracts of territory in Laos and Cambodia to France (1893, 1904, 1907) and on the Malay Peninsula to Great Britain (1909). Skillfully using a series of Belgian and American advisers, Devawongse devoted his last two decades in office to ending Western extraterritoriality in Siam, an effort that proved successful in the months immediately following his death.

development, in biology, the progressive changes in size, shape, and function during the life of an organism by which its genetic potentials (genotype) are translated into functioning adult systems (phenotype).

A brief treatment of biological development follows. For full treatment, see MACROPAEDIA: Growth and Development, Biological.

The simplest form of development is a change (usually an increase) in size of an organ system or structure; simple growth, how-

ever, seldom occurs without accompanying chemical or functional changes. In general, biological development consists of an increase in both size and complexity of the entire organism and of its component organs, but under some circumstances, as when an early motile stage metamorphoses into a sessile or parasitic adult, loss or reduction of certain structures may occur. Development may be divided into morphogenesis, the process by which organ systems become structurally distinct, and differentiation, the process by which cells and tissues adopt specific and unique biological functions. In most cases the two processes concur, because a specific structure may be required to fulfill a necessary physiological function. In both plants and animals, these processes may occur at different rates in different organ systems; the human brain, for example, may reach its full adult size and complexity before the reproductive system has even begun its adult development.

Animal and plant development follow very different paths. Plants in general employ a type of multiphasic development, in which two distinct forms succeed each other in alternating generations; one form, created by the union of sexual cells (gametes), contains two sets of similar chromosomes (diploid). At sexual maturity, this form, called the sporophyte, produces an offspring (gametophyte) with cells containing only one set of genetic instructions (haploid). At their sexual maturity, gametophytes produce haploid gametes that unite to begin a new cycle.

Animal cells also go through a haploid phase, but the reduction of chromosomes occurs only within the sex organs of the diploid parents; gametes from the two parents immediately reunite to form a diploid embryo, without an intervening haploid generation. The male sperm fertilizes a female ovum to form the zygote, which immediately begins to divide into many smaller cells (cleavage). The embryos of animals that lay their eggs on land, such as reptiles and birds, are nourished by a yolk throughout development. Lower vertebrates that lay their eggs in water have smaller yolks and hatch less-developed offspring, which draw their nutrients directly from their environment. Most mammals have very small eggs that attach to the mother's uterus and that develop a placenta, by which nutrients are transmitted from mother to child.

After several divisions, the animal embryo forms a hollow ball called a blastula, which differentiates into three types of cells (ectoderm, mesoderm, and endoderm). In gastrulation, these cells migrate into their proper positions: ectoderm, from which develop the skin, sense organs, and nervous system, on the outside; endoderm, from which develop the digestive tract, urinary system, and lungs, on the inside; and mesoderm, from which develop muscles, skeleton, and connective tissues, between the two.

Gastrulation is followed by organogenesis, during which process the various organ systems of the adult first begin to take primitive shape. A fold on the embryo's surface closes off into a tube that further subdivides by constriction and dilation of the cell mass, as in the nervous system. A pocket in the tissue's surface gradually lengthens and branches, as in the vertebrate lung, and local thickenings develop from primordial tissues, as in the development of the musculoskeletal system of vertebrates.

Development in many organisms is not completed at birth. Many invertebrates (including insects) and lower vertebrates hatch as distinctly different forms, called larvae, which feed and grow until they have sufficient mass to sustain life as adults. Then, structures with functional importance to the larva but not to the adult (e.g., a tadpole's tail) disintegrate, while new structures (e.g., a frog's legs) are created from embryonic tissues that remained

quiescent during the larval stage. This transformation is called metamorphosis.

Other vertebrates, such as the mammals, are born as essentially miniature adults requiring minor further development. The sex organs are incomplete at birth, and their maturation constitutes the transition to adulthood. In humans, for example, much of the postnatal development occurs during puberty, when secondary sexual characteristics such as pubic and facial hair appear, female breasts develop, and mature sex cells are produced by the male testes and female ovaries.

All plants develop through two distinct generational forms, although in some, as in the algae, the physical appearance of succeeding generations is identical, while in others, as in the flowering plants, one of the forms (usually the haploid gametophyte) goes through its entire life cycle within the body of the parent. Among higher plants, the male gametophyte may consist of as few as three cells, which form a pollen grain that is carried by the wind, water, or animals to the female gametophyte within the female flower. The male then grows through the tissues surrounding the female reproductive cell to fertilize it, again forming a zygote. As in the animal, the zygote divides into smaller cells, which quickly become differentiated; after only three cell divisions, the cells' eventual development into seed leaves (cotyledons), shoot, root, and hypocotyl (the part of the shoot between the cotyledons and the root) has already been determined. Development continues until a tiny plant, or seedling, is formed; at this point, further development may be arrested in the higher plants until germination, which usually occurs after the seed has been dispersed and encounters environmental conditions propitious for growth.

At germination, the seedling first grows larger simply by absorbing water from its environment, but it soon begins active growth through the division of cells at growth zones (meristems) at the tip of the root and shoot. Each cell division in the meristem produces one dividing cell to continue growth and a vegetative cell that helps extend the plant behind the growing tip. Smaller clusters of meristematic cells at intervals along the stem produce leaves, the shape of which is determined by the rate of growth of different cells within the meristem. Branches of the original meristem produce secondary roots underground and lateral branches from the shoot.

Within the plant, vegetative cells produced by the meristem form long chains behind it. In some of these chains, a stiff compound called lignin is deposited, cutting off diffusion across the cell wall and killing the cell; the empty cell walls form long tubes, called xylem, through which water flows. Other molecules, cutin and suberin, are deposited in the walls of cells on the outer surface of the stem, creating the cork and phloem, which carries nutrients and other substances through the plant. New vascular cells are produced by a layer of reproductive tissue, the cambium, between the layers of vascular tissue. The entire growth process is controlled by plant hormones called gibberellins.

development bank, national or regional financial institution designed to provide medium- and long-term capital for productive investment, often accompanied by technical assistance, in less-developed areas.

The number of development banks has increased rapidly since the 1950s; they have been encouraged by the International Bank for Reconstruction and Development and its affiliates. The large regional development banks include the Inter-American Development Bank, established in 1959; the Asian

Development Bank, which began operations in 1966; and the African Development Bank, established in 1964. They may make loans for specific national or regional projects to private or public bodies or may operate in conjunction with other financial institutions. One of the main activities of development banks has been the recognition and promotion of private investment opportunities. Although the efforts of the majority of development banks are directed toward the industrial sector, some are also concerned with agriculture.

Development banks fill a gap left by undeveloped capital markets and the reluctance of commercial banks to offer long-term financing. Development banks may be publicly or privately owned and operated, although governments frequently make substantial contributions to the capital of private banks. The form (share equity or loans) and cost of financing offered by development banks depend on their cost of obtaining capital and their need to show a profit and pay dividends.

developmental psychology, also called **LIFESPAN PSYCHOLOGY**, the branch of psychology concerned with the changes in cognitive, motivational, psychophysiological, and social functioning that occur throughout the human life span. During the 19th and early 20th centuries, developmental psychologists were concerned primarily with child psychology. In the 1950s, however, they became interested in the relationship between personality variables and child rearing, and the behavioral theories of B.F. Skinner and the cognitive theories of Jean Piaget were concerned with the growth and development of children through adolescence. At the same time, the German psychologist Erik Erikson insisted that there are meaningful stages of adult psychology that have to be considered in addition to child development. Psychologists also began to consider the processes that underlie the development of behaviour in the total person from birth to death, including various aspects of the physical-chemical environment that can affect the individual during the intrauterine period and at birth. By the latter part of the 20th century, developmental psychologists had become interested in many broad issues dealing with the psychological process throughout life, including the relation of heredity and environment, continuity and discontinuity in development, and behavioral and cognitive elements in the development of the total person. *See also* child psychology; psychological development.

Deventer, *gemeente* (commune). Overijssel *provincie*, east-central Netherlands, on the IJssel River at the west end of the Overijssel Canal. Deventer developed in the 8th century around a chapel established by St. Lebinius. During the Middle Ages it prospered as a member of the Hanseatic League, had a monopoly of the dried-cod trade, and was noted for its five annual fairs. It became a famous medieval intellectual centre, where the saintly scholar Thomas à Kempis, the great humanist Erasmus, and Pope Adrian VI studied. In the 14th century, Gerhard Groote founded his religious movement, the Brethren of the Common Life, in Deventer. The town was the most important Dutch printing centre about 1500.

Famous for its carpets, tapestries, and honey cakes (*Deventerkoek*), it also has machine shops and foundries and manufactures bicycles and bricks. Medieval buildings include the Grote Kerk, with an 11th-century crypt; the Bergkerk (St. Nicholas Church); the town hall (dating from the 13th century); and the Gothic Weighhouse (1528), now a museum. Parts of the old city walls remain. Deventer has a municipal museum and a museum of tropical agriculture, and its Athenaeum Li-

brary houses valuable manuscripts from the 10th century. Pop. (1989 est.) 66,398.

Deventer, Conrad Theodor van (b. Sept. 29, 1857, Dordrecht, Neth.—d. Sept. 27, 1915, The Hague), Dutch jurist and statesman whose pamphlet *Een eereschuld* ("A Debt of Honour") and ideas had a profound influence on the development of the colonial Ethical Policy in the Dutch East Indies.

Van Deventer, educated in the law, left in 1880 for the Indies, where he worked as a lawyer and held various judicial posts. The outer islands (*i.e.*, those outside Java) were of particular interest to him. On returning to The Netherlands in 1897, he joined the Liberal Democratic Party and drafted a new colonial program that emphasized welfare of the indigenous peoples, decentralization of administrative authority, and employment of more Indonesians in high government positions. In 1899 *Een eereschuld* appeared in *De Gids*, a progressive periodical. The Dutch, he insisted, should repay the full amount that had been extracted from the Indies since 1867 (when Parliament took over responsibility for the colonies) by pouring money into the Indies' education and economy. His suggestions formed the basis of the Ethical Policy, which was adopted in 1901 and which recognized the moral responsibilities of Dutch guardianship of the Indies.

Van Deventer served twice in Parliament, in 1905–09 and from 1913 until his death.

Devereux, Robert: *see* Essex, Robert Devereux, 2nd Earl of; Essex, Robert Devereux, 3rd Earl of.

Devereux, Walter: *see* Essex, Walter Devereux, 1st Earl of.

Devers, Jacob L., in full **JACOB LOUCKS DEVERS** (b. Sept. 8, 1887, York, Pa., U.S.—d. Oct. 15, 1979, Washington, D.C.), U.S. general during World War II, whose 6th Army Group successfully penetrated German-held positions in central Europe and helped wrest the mainland from Nazi control.

At the outbreak of World War II (1940), Devers was commanding general of the 9th infantry division, becoming chief of armoured forces from 1941 to 1943. After serving as commanding general of the European theatre of operations in 1943, he became in the next year commander of the North African theatre and deputy supreme Allied commander of the Mediterranean theatre.

Devers was next appointed (September 1944) commander of the 6th Army Group, made up of U.S. and French forces. In early 1945 his units cleared Alsace, crossed the Rhine River, and swept through southern Germany to the Swiss border, eventually entering Austria and linking up with Allied forces in northern Italy. He headed the army ground forces before his retirement in 1949.

Devey, George (b. 1820, London, Eng.—d. November 1886, Hastings, East Sussex), British architect who influenced nonacademic architects in England in the late 19th and early 20th centuries.

Devey was educated in London and studied painting before he trained as an architect. His considerable, and exclusively domestic, practice included designs for lodges, cottages, and country mansions containing design elements from the 15th to the 17th century. He directly influenced William Eden Nesfield and C.F.A. Voysey, who as a young man worked for Devey. Particularly influential was a Devey brick house at Betteshanger, Kent (1857), which was studied carefully by Nesfield and by the school architects E.R. Robson and J.J. Stevenson. The London School Board's standard design from 1870, when Robson became its official architect, was based on this residence. During his lifetime Devey was best known for altering and enlarging country

mansions, *e.g.*, Penshurst Place, Kent. The necessary derivativeness of this type of work and Devey's aversion to publicity concealed his true importance, which was overlooked by architectural historians until the middle of the 20th century.

devil (from Greek *diabolos*, "slanderer," or "accuser"), the spirit or power of evil. Though sometimes used for minor demonic spirits, the word devil generally refers to the prince of evil spirits and as such takes various forms in the religions of the world.

In the monotheistic Western religions, the devil is viewed as a fallen angel who in pride has tried to usurp the position of the one and only God. In Judaism, and later Christianity, the devil was known as Satan. In the Old Testament, Satan is viewed as the prosecutor of Yahweh's court, as in Job, chapters 1 and 2, but he is not regarded as an adversary of God. In postbiblical Judaism and in Christianity, however, Satan became known as the "prince of devils" and assumed various names: Beelzebub ("Lord of Flies") in Matthew 12:24–27, often cited as Beelzebul ("Lord of Dung"), and Lucifer (the fallen angel of Light).

In Christian theology the devil's main task is that of tempting man to reject the way of life and redemption and to accept the way of death and destruction. The leader of the angels who have fallen from heaven because of pride, Satan has as his main adversary in Christian thought, legend, and iconography the archangel Michael, leader of God's heavenly hosts.

Islamic theology is rich in references to Iblis, the personal name of the devil, who is also known as ash-Shayṭān ("The Demon") and 'aduw Allah ("Enemy of God"). In the Qur'an, Iblis first appears in the story of the creation of the world. He alone of the angels refuses God's order to bow before Adam, the first man. He is then cursed by God; his punishment is to come on the Day of Judgment, but until then he is empowered to tempt the unfaithful (but not true believers). Iblis next appears as the tempter of Adam and Eve in the Garden of Eden. In Islamic theology, Iblis is described as an angel, a *jinn* (spiritual creature capable of good or evil), or an angel who was the leader of the *jinni*. The questions of his sins of pride and disobedience are especially important in the Sūfī traditions, in which he is sometimes presented as a true monotheist who would bow only to God.

"Lucifer's Descent into Hell," illumination from *Queen Mary's Psalter*; in the British Library, MSS Royal 2B VII

The devil was also an important figure in certain syncretic religions. In Gnosticism the devil was often called the Demiurge (the Creator) and in Manichaeism the Prince of Darkness, as well as other names.

The devil, as the great power of evil, has been much depicted in religious and secular literature and art. At various intervals in history, devil worship becomes significant for certain individuals dissatisfied with existing religious institutions, and exorcism is often consequently reinstated by these institutions.

"De," "la," and similar components of a name, when followed by a space, are alphabetized as separate words (e.g., De Forest, Lee). When they are joined to the following part of a name, the combination is treated as a single word (e.g., DeForest, John William).

devil ray, also called MANTA RAY, any of several genera of marine rays comprising the family Mobulidae (class Selachii). Flattened, and wider than they are long, devil rays have fleshy, enlarged pectoral fins that look like wings; extensions of these fins, looking like devils' horns, project as the cephalic fins from the front of the head. Devil rays have long, whiplike tails provided, in some species, with one or more stinging spines.

Devil rays, related to sharks and skates, are found in warm waters along continents and islands. They swim at or near the surface, propelling themselves by flapping their pectoral fins and, at times, leaping or somersaulting out of the water. They feed on plankton and small fishes that they sweep into their mouths with their cephalic fins.

The smallest of the devil rays, species *Mobula diabolis* of Australia, grows to no more than 60 cm (2 feet) across, but the Atlantic

Atlantic manta (*Manta birostris*)
Painting by Richard Ellis

manta, or giant devil ray (*Manta birostris*), largest of the family, may grow to more than 7 m (23 feet) wide. The Atlantic manta is a well-known species, brown or black in colour and very powerful, but inoffensive. It does not, old tales to the contrary, envelop pearl divers and devour them.

devil worship: *see* satanism.

Deville, Édouard Gaston (Daniel) (b. Feb. 21, 1849, La Charité, Fr.—d. Sept. 21, 1924, Ottawa, Ont., Can.), French-born Canadian surveyor of Canadian lands (1875–1924), who perfected the first practical method of photogrammetry, or the making of maps based on photography.

Deville served in the French navy, conducting hydrographic surveys in the South Sea islands, Peru, and elsewhere until 1874. He then went to Canada, where he was appointed (1875) inspector of surveys in the province of Quebec. In 1881 he became inspector of Dominion land surveys and four years later surveyor general. Deville devised a system of making maps by plotting intersections from

photographs taken from tripods on the ground. Among his several articles and books is *Photographic Surveying* (1895).

Deville, Henri-Étienne Sainte-Claire: *see* Sainte-Claire Deville, Henri-Étienne.

devil's advocate, Latin *ADVOCATUS DIABOLI*, in the Roman Catholic church, the promoter of the faith, who critically examines the life of and miracles attributed to an individual proposed for beatification or canonization. He is popularly called the devil's advocate because his presentation of facts includes everything unfavourable to the candidate. Pope Leo X, in the early 15th century, seems to have introduced the term, but Sixtus V formally established the office in 1587.

devil's arrow, also called DEVIL'S DARNING NEEDLE: *see* dragonfly.

Devils Island, French *ÎLE DU DIABLE*, rocky islet off the Atlantic coast of French Guiana. The smallest of the three Îles du Salut, about 10 miles (16 km) from the mainland and the Kourou River mouth, it is a narrow strip of land about 3,900 feet (1,200 m) long and 1,320 feet (400 m) broad, mostly covered by palm trees.

Part of a penal settlement, the island housed the convicts' leper colony until the Îles du Salut were made a maximum-security area. The island's most famous prisoner was Alfred Dreyfus, a French army officer unjustly condemned for treason, who arrived on April 13,

Devils Island off the coast of French Guiana
Bjorn Klingwall—Ostman Agency

1895; he was released on June 5, 1899, having written a journal and more than 1,000 letters in captivity. Dreyfus was succeeded by other political prisoners and, during World War I, by spies and deserters, chiefly from tropical countries and not of French birth. Transportation of prisoners to French penal colonies was abolished by a decree of June 17, 1938, although the last prisoners did not leave Devils Island until 1953.

The island was later promoted as a winter resort and has a growing tourist trade.

Devils Lake, city, seat of Ramsey county, northeast-central North Dakota, U.S. The community was established with the opening of a land office in 1882 as Creelsburg (later Creel City) and was the head of steamboat navigation on Devils Lake, a saline body of water originally about 30 miles [50 km] long. By 1909, when the lake had receded 4 miles (6 km) from the city, navigation ceased. The city developed as a trade centre for an agricultural area producing grain, livestock, poultry, and dairy products. Chief manufactures are sheet-metal products, flour, farm implements, and liquid fertilizer. The city is the site of Lake Region Junior College (1941). The Sully's Hill National Game Preserve is 12 miles (19 km) southwest. Fort Totten Indian Reservation is 15 miles (24 km) south. Inc. city, 1894. Pop. (1990) 7,782.

Devils Postpile National Monument, national monument in Madera county, east-central Calif., U.S., situated on the middle fork of the San Joaquin River. The formation

consists of polygonal basaltic columns some 40 to 60 feet (12 to 18 m) tall and 10 to 30 inches (25 to 75 cm) in diameter. It was created some 900,000 years ago by the cooling and cracking of hot lava. Devils Postpile,

Basaltic columns at Devils Postpile National Monument, Madera county, Calif.
Kirkendall/Sprung

which consists of 798 acres (323 hectares) of land, was proclaimed a national monument on July 6, 1911.

Devils Tower National Monument, the first U.S. national monument, established in 1906 in northeastern Wyoming, U.S., near the Belle Fourche River. It encompasses 1,347 acres (545 hectares) and features a natural rock tower, the remnant of a volcanic intrusion now exposed by erosion. The tower has a flat top and fluted sides and is 865 feet (263 m) high. It probably formed when molten rock, pushing upward, encountered a hard-rock layer and was forced to spread into a flat-topped shape. Its colour is mainly light gray

Devils Tower National Monument, Wyoming

and buff. Lichens cover parts of the tower, and sage, moss, and grass grow on its top. Chipmunks and birds live on the summit, and a pine forest covers some of the surrounding country. The monument contains a museum and campground.

devitrification, process by which glassy substances change their structure into that of crystalline solids. Most glasses are silicates in which the atomic structure does not have the repetitive arrangement required for the formation of crystals. Glass is formed by the cooling of a rock magma too rapidly for this structural regularity to become established. Glasses typically are not stable at low temperatures, however, and a readjustment of the atomic arrangement may take place to form more stable structures. This devitrification process is very slow, but over millions of years, a glass will form a completely crystalline mass.

Devizes, town ("parish"), Kennet district, administrative and historical county of Wiltshire, England. It lies along the disused Kennet and Avon Canal, at the edge of Roundway Down. It was the site of a Roman fortification, *Castrum Divisarum*, and in about 1132 Roger, bishop of Salisbury, built a castle there. The name Devizes possibly came from a medieval Latin reference to the castle *ad divisas* ("at the boundaries"). The town that grew around the castle received its first charter in 1141, was represented in Parliament from 1295, and had an important medieval market. The castle was razed in 1645 by the army of Oliver Cromwell. Devizes today is a grain, cattle, and pig market and has bacon and cheese factories, tileworks, and engineering plants. Until the 1950s it was a noted manufacturer of snuff. Pop. (1991) 13,205.

Devolution, War of (1667–68), conflict between France and Spain over possession of the Spanish Netherlands (present-day Belgium).

Devolution was a local custom governing the inheritance of land in certain provinces of the Spanish Netherlands, by which daughters of a first marriage were preferred to sons of subsequent marriages. Louis XIV of France began the war on the pretext that this custom should apply to sovereign territories also, so that his wife, Marie-Thérèse, should succeed her father, Philip IV of Spain (d. 1665), in the majority of the Spanish possessions in the Netherlands in preference to her younger half-brother, Charles II of Spain, a sickly epileptic unlikely to live long or produce heirs.

The French army under Marshal de Turenne advanced into Flanders in May 1667 and easily secured its objectives. Louis then turned to diplomacy and in January 1668 concluded a treaty with the Holy Roman emperor Leopold I whereby they agreed to partition the Spanish dominions between themselves on the Spanish king's death and in which it was also stipulated how much territory in the meantime France was to annex in the Netherlands. The French had also tried to win English support for their claims, but a new ministry in England turned instead to an alliance with the Dutch and with Sweden. These allies sought to contain the French advance by persuading Spain to agree to moderate terms and by supporting Spain in war if this proved of no avail. The settlement envisaged was much the same as that on which Louis XIV and the emperor had agreed, and so peace was soon concluded at Aix-la-Chapelle in April 1668.

Devon, administrative, geographic, and historic county of England, forming part of the Southwest Peninsula of Great Britain and bounded on the west by Cornwall and on the east by Dorset and Somerset. The administrative, geographic, and historic counties cover slightly different areas. The historic county comprises the entire geographic county as well as a small area along the border of the district of West Dorset in the administrative county of Dorset and a larger area extending west from Werrington along the River Otter within the district of North Cornwall in the administra-

tive county of Cornwall. The geographic county of Devon is England's third largest. It encompasses the administrative county and the unitary authorities of Plymouth and Torbay. The administrative county comprises the districts of East Devon, Mid Devon, North Devon, South Hams, Teignbridge, and Torridge; the borough of West Devon; and the city of Exeter.

Within Devon's boundaries is a wide variety of scenery, including the Dartmoor National Park and, in the north, part of the Exmoor National Park. Dartmoor, with shallow marshy valleys, thin fertile soils, and a vegetation of coarse grasses, heather, and bracken, is a granite plateau rising to more than 2,000 feet (600 m), the crests capped by granite tors (rocky peaks); the moor is used for rough grazing, reforestation, reservoirs, and military training and is a popular area for tourists. Exmoor, reaching more than 1,575 feet (480 m), is another plateau where rough grazing and tourism are important, but it has more farmland than Dartmoor. These two areas of moorland contain the main sources of rivers for the county. From Dartmoor the rivers flow in a radial pattern to the north and south coasts and to the River Tamar; from Exmoor they flow seaward via the River Exe and northward to the Bristol Channel. Much of central and northwestern Devon is given over to grassland. The soils in South Hams, south of Dartmoor, often produce good farmland. The most fertile soil is in southeastern Devon. The county's generally mild climate becomes more extreme with elevation and distance from the sea, and rainfall increases from about 30 inches (760 mm) on the south coast to more than 60 inches (1,500 mm) on Exmoor and 80 inches (2,000 mm) on Dartmoor.

Prehistoric remains abound; they include the limestone caves near Torquay (including Kent's Cavern, one of the two oldest human dwellings in Britain), numerous high-altitude Bronze Age remains on Dartmoor, and later Iron Age hill forts and earthworks fringing the moor and guarding river routes. The largest, Hembury Fort, was probably the capital of the Dumnonii, a British tribe, until the foundation of Exeter as a Roman frontier station at the termination of Fosse Way. The Dumnonii survived the 7th-century Saxon conquests, but both Saxon and Briton became subjects of Wessex. Devon was recognized as a shire in the late 8th century and suffered subsequently from Danish raids (851–1003). The Saxons created four strongholds, called *burhs*, at Exeter, Barnstaple, Totnes, and Lydford. Exeter was taken by the Norman William I the Conqueror in 1068, and a castle was built there in 1348. The Normans built castles at Totnes, Okehampton, and Plympton; these, like the *burhs*, acted as nuclei for the growth of towns.

Tin mining on Dartmoor was important from the 12th to the 17th century. The ports of Exeter, Plymouth, Barnstaple, and Dartmouth thrived from medieval times on the export of tin and cloth until these both declined in the 19th century, causing rural depopulation that was alleviated only by the rise of tourism, which rapidly increased during the railway era. By the 19th century, lead, silver, iron ore, copper, and manganese had all been worked.

Agriculture is Devon's most valuable single industry; about 30 percent of the working population is dependent on agriculture and related industries. It is based on livestock (supported by permanent grassland and ley), cereals (especially barley), potatoes, market gardening, horticulture, fruit, and fodder crops. About 25 percent of the country is heath or moorland. Dairy cattle are most important in eastern, northwestern, and southern Devon, and Devonshire clotted cream is still produced. Beef cattle are raised throughout, especially in the south and west. Sheep are important throughout the county, including

Dartmoor and Exmoor, with the exception of eastern Devon. Between 1964 and 1980 the number of farm holdings fell by 25 percent, but the average size increased. Soft fruit and flowers are grown in sheltered areas, but traditional cider orchards are declining in acreage, and the cider is now produced in factories.

Tourism dominates the coastal areas and is also important in the rural interior. The main resorts, apart from Ilfracombe, lie on the south coast and include Torbay, Paignton, and Brixham. Both coasts abound with picturesque small towns and villages, such as Salcombe, Lynmouth, and Clovelly.

Service trades employ two-thirds of the working population, more than the national average, reflecting the importance of tourism and the large retired population that is attracted by the mild winter climate and scenery.

Fishing is still important, especially at Brixham and Plymouth, which also has an important naval base. Kaolin (china clay) from Dartmoor and ball clay from the Bovey basin are the chief mineral exports. Local industries include textiles (Tiverton), dairy produce (Totnes), glass (Dartington), woollens (Axminster), lace (Honiton), and the complex industries of the Devonport dockyard. Plymouth and Exeter are the main industrial centres, followed by Torbay, Barnstaple, and Newton Abbot. Devon's main centres of population are coastal, except Exeter. The three main urban areas that act as the major retail and service centres are Plymouth, Exeter, and Torbay. Exeter, the cathedral and university city, is the long-established seat of county administration. Area administrative county, 2,533 square miles (6,561 square km); geographic county, 2,588 square miles (6,703 square km). Pop. (1998 est.) administrative county, 692,400; geographic county, 1,068,400.

Devonian period, interval of geologic time from 408 to 360 million years ago. The fourth period of the Paleozoic era, it follows the Silurian and precedes the Carboniferous. The Devonian is often divided into the Early Devonian epoch (408 to 387 million years ago), Middle Devonian epoch (387 to 374 million years ago), and Late Devonian epoch (374 to 360 million years ago). The rocks that originated during the period comprise the Devonian system.

A brief treatment of the Devonian period follows. For full treatment, see *MACROPAEDIA: Geochronology*.

Rocks of the Devonian system are found in every continent, but they were first recognized as a major group in the counties of Devon and Cornwall in southwestern England. The research of geologists Sir Roderick I. Murchison and Adam Sedgwick established the Devonian in 1839. Their work was corroborated by European and American investigators.

The period was one of significant changes in world paleogeography. The physiognomy of the Earth was substantially different from what it is today; a giant continent was situated in the Southern Hemisphere, and other land masses were located in the equatorial regions. Siberia was separated from Europe by a broad ocean. The continents of North America and Europe had collided during the Early Devonian, resulting in the Caledonian orogeny (mountain-building episode). This event involved much igneous activity, as, for example, the intrusion of huge granitic bodies known as plutons. In the Middle Devonian, the Acadian mountain-building episode took place in northern Appalachia in what is now the eastern United States. There were also major movements of the tectonic plates in northern and western North America, western South America, East Asia, and eastern Australia. Many parts of the world also experienced intense volcanism and seismic activity.

The equatorial seas separating the continents contained extensive reefs built by corals and

other organisms. Large landlocked areas of shallow sea in North America, Central Asia, and Australia became evaporite basins in which great quantities of rock salt, gypsum, and other minerals were precipitated. On the continental platforms themselves and at their margins, vigorous erosion of the uplifted mountainous areas produced great volumes of coarse sediment, which were deposited in the lowlands and seas to become the Old Red Sandstone formations. Desert conditions prevailed in many areas, whereas in others there was abundant rainfall. The Devonian year is thought to have had some 400 days, each consisting of about 21 hours. This would have had a small but not insignificant effect on tides and perhaps rates of coastal erosion, aiding the rapid spread of the seas.

Evidence indicates that the volcanic activity along the fissures of oceanic ridges was influential in the great flooding of the continents in Devonian times. As the ridges grew with the extrusion of molten rock, the ocean waters rose onto the margins of the continents, covering by Late Devonian times a substantially larger percentage of the Earth than today.

The Devonian was characterized by varied faunal and floral life forms. Among the marine invertebrates, the bivalve brachiopods and conodonts became highly diversified and abundant. The mollusks made evolutionary strides, and the ammonoids (a group of now-extinct cephalopods) emerged, evolving from their continuing nautiloid ancestors. Corals and similar animals were abundant, and reef habitats for other invertebrates became widespread. By contrast, the graptolites became extinct and the trilobites declined (only the protaceans survived).

Many types of primitive fish appeared and proliferated in both marine and freshwater environments during the Devonian. Because of this, the period is commonly referred to as the "Age of Fishes." Jawless, heavily armoured varieties (those of the class Agnatha) developed, as did sharklike forms and lungfish. By the end of the period the rhipidistians, a group of air-breathing, lobe-finned bony fishes, apparently gave rise to four-footed amphibians.

Vascular plants underwent tremendous diversification during Devonian times. The colonization of ferns and primitive gymnosperms resulted in the formation of the first forests, such as the Gilboa forest in the northeastern United States. These were the forerunners of the great swamp forests of the Carboniferous Period (from 360 to 286 million years ago).

Toward the end of the Devonian, a number of marine invertebrates suffered extinction. Particularly hard hit were the colonial tabulate corals, stromatoporoids, and various other groups associated with the reef environment.

No hypothesis explaining this worldwide event has been entirely acceptable. More plausible causes include the deepening of the shallow shelf seas, which led to the destruction of the reefs and related fauna, or the widespread occurrence of anoxic (oxygen-deficient) conditions following the major transgression and regression of oceanic waters at this time.

Devonport, town, northern Tasmania, Australia. It lies near the mouth of the River Mersey, which empties into Bass Strait. One of the state's largest communities, it was formed through the amalgamation in 1893 of the villages of Torquay (east bank) and Formby (west), both of which had been founded in the 1850s. A major service centre with port facilities, Devonport is on the Bass Highway and a rail line (freight only) to Launceston, 45 miles (70 km) southeast, and has ferry and air links to Melbourne. The city exports paper, textiles, carpets, processed foods, potatoes, cement, and sawed timber. Pop. (1986) 22,645.

Devonshire, EARLS AND DUKES OF, titled English nobility of two creations, in the families Blount and Cavendish, grouped below

chronologically and indicated by the symbol ●.

● **Devonshire, Charles Blount, Earl of:** *see* Mountjoy, Charles Blount, 8th Lord.

● **Devonshire, William Cavendish, 1st Earl of, BARON CAVENTISH OF HARDWICK** (b. Dec. 27, 1552—d. March 3, 1626, Hardwick Hall, Devonshire, Eng.), first of the long line of Devonshire peers.

The son of Sir William Cavendish and his third wife, Elizabeth Hardwick (afterward the Countess of Shrewsbury), the young Cavendish was educated at Eton College and Gray's Inn and was knighted in 1580 and created a baron in 1605. In 1608 he inherited a rich estate from his mother and later became a sponsor of the Virginia Company and a cograntee of Bermuda. James I created him Earl of Devonshire in 1618. His great-grandson became the 4th Earl and 1st Duke of Devonshire.

● **Devonshire, William Cavendish, 1st Duke of, MARQUESS OF HARTINGTON, EARL OF DEVONSHIRE, BARON CAVENTISH OF HARDWICK** (b. Jan. 25, 1640—d. Aug. 18, 1707, London, Eng.), a leader of the parliamentary movement that sought to exclude the Roman Catholic James, Duke of York (afterward James II), from succession to the British throne and that later invited the invasion of William of Orange.

Cavendish was the eldest son of the 3rd Earl of Devonshire (and succeeded to the title in 1684). On his return from a youthful grand tour of Europe, in 1661, he took a seat in Parliament and soon became conspicuous as one of the most determined opponents of the general policy of the court of Charles II. In 1679 he was made a privy councillor by Charles II, but he soon withdrew from the board with his friend Lord William Russell (afterward 1st Duke of Bedford) when he found that the Roman Catholic interest uniformly prevailed. Devonshire carried up to the House of Lords the articles of impeachment against Lord Chief Justice Scroggs, for his arbitrary proceedings in the Court of King's Bench; and, when Charles II declared his resolution not to sign the bill for excluding the Duke of York from the succession, Devonshire moved in the House of Commons that a bill might be brought in for the association of all his majesty's Protestant subjects. He also openly denounced the king's counselors.

Devonshire appeared in defense of Lord Russell at the latter's trial and, after Russell's condemnation, offered to exchange clothes with him in the prison, remain in his place, and so allow him to effect his escape.

He opposed the government under James II and, for quarreling at court, was fined and briefly imprisoned. The Revolution of 1688 again brought him into prominence. He was one of the seven who signed the original paper inviting William of Orange to England and was made lord high steward of the new court.

He was created Marquis of Hartington and Duke of Devonshire in 1694 by William and Mary, on the same day on which the head of the house of Russell was created Duke of Bedford. His last public service was assisting to conclude the union of England and Scotland (1707).

● **Devonshire, William Cavendish, 4th Duke of, MARQUESS OF HARTINGTON, EARL OF DEVONSHIRE, BARON CAVENTISH OF HARDWICK** (b. 1720—d. Oct. 3, 1764, Spa, Liège, Austrian Netherlands [now in Belgium]), prime minister of Great Britain from November 1756 to May 1757, at the start of the Seven Years' War.

Eldest son of William Cavendish, the 3rd Duke (1698–1755), he was elected to the House of Commons in 1741 and 1747, and in 1751 he moved to the House of Lords, as Lord Cavendish of Hardwick, in his father's barony. After becoming lord lieutenant

and governor-general of Ireland (1754), he succeeded to the dukedom (1755); and the following year he agreed to become nominal prime minister. William Pitt had refused to serve in the ministry of the Duke of Newcastle, and the great Whig families balked at Pitt himself becoming prime minister. Thus, Devonshire was summoned to the post, while Pitt became the ministry's real authority as secretary of state to manage the war. When Pitt reconciled with Newcastle the following year, Devonshire, without having made much of a mark on events, resigned and became lord chamberlain of the household, a post he held until 1762.

● **Devonshire, Spencer Compton Cavendish, 8th Duke of, MARQUESS OF HARTINGTON, EARL OF DEVONSHIRE, BARON CAVENTISH OF HARDWICK** (b. July 23, 1833, Lower Holker, Lancashire, Eng.—d. March 24, 1908, Cannes, Fr.), British statesman whose opposition to the Irish Home Rule policy of his own Liberal Party caused him to assume (1886) the leadership of the Liberal Unionist Party and to become increasingly

Spencer Compton Cavendish, 8th Duke of Devonshire, watercolour by Julia, Lady Abercromby, 1888; in the National Portrait Gallery, London

National Portrait Gallery, London

identified with the Conservatives. On three occasions (1880, 1886, and 1887) he declined the office of prime minister.

Entering the House of Commons in 1857, Lord Hartington was secretary of state for war from February to July 1866. During William Gladstone's first prime ministership, he was postmaster general (1868–71), directing the nationalization of the British telegraph services, and afterward was chief secretary for Ireland. In January 1875, when Gladstone temporarily retired from politics, Hartington became the Liberal leader in the House of Commons. In Gladstone's second administration (1880–85), Hartington was secretary of state for India until December 1882, and then he returned to the war office. He shared the responsibility for assigning General Charles George ("Chinese") Gordon to evacuate British troops from the Sudan in 1884, but he repeatedly and unsuccessfully urged the Cabinet to hasten the expedition to relieve Gordon.

Throughout this period, Hartington led the Cabinet opposition to conciliating the Irish nationalists. Gladstone's attempt to placate him through his younger brother Lord Frederick Cavendish, who was made Irish secretary May 4, 1882, resulted in the tragedy of Lord Frederick's murder in Dublin two days later. When Gladstone became premier once more in February 1886, Hartington rejected his chief's conversion to full Irish Home Rule and

became the leader of the new Liberal Unionist Party. In June he secured the defeat of Gladstone's Home Rule Bill in the House of Commons and the fall of the government. Robert Arthur Talbot Gascoyne-Cecil, 3rd marquess of Salisbury, leader of the Conservative Party, on finding that his majority in the House of Commons depended on the Unionists, offered to serve in a ministry headed by Hartington, who, however, declined this proposal twice (July 1886 and January 1887).

In September 1893 the Duke of Devonshire (as he had become in 1891) led another defeat of a Gladstonian Home Rule bill, this time in the House of Lords. Refusing the foreign secretaryship in 1895, he served in Lord Salisbury's third ministry (1895–1902) and in the subsequent Conservative government of Arthur James Balfour (1902–05) as lord president of the council, with responsibility for the school system. Strongly believing in free trade, he resigned over that issue in October 1903. Among the Unionists, his free traders were outnumbered by those who supported the imperial protectionism of Joseph Chamberlain, the colonial secretary; and in May 1904 the Duke resigned as Liberal Unionist Association chairman in favour of Chamberlain.

The Life of Spencer Compton, Eighth Duke of Devonshire, 2 vol. (1911), was written by his private secretary, Bernard Holland.

devotio moderna, religious movement within Roman Catholicism from the end of the 14th to the 16th century stressing meditation and the inner life, attaching little importance to ritual and external works, and downgrading the highly speculative spirituality of the 13th and 14th centuries. *Devotio moderna* (Latin: "modern devotion") originated in the Netherlands and spread to Germany, northern France, Spain, and possibly Italy. Gerhard Groot, father of the movement, founded the Brethren of the Common Life; after his death, disciples established a house of Augustinian Canons at Windesheim (near Zwolle, Holland). These two communities—the former living in the world, the latter monastic—became the principal exponents of *devotio moderna*. The *Imitation of Christ*, traditionally attributed to Thomas à Kempis, is a classic expression of the movement.

Devrient, Eduard (b. Aug. 11, 1801, Berlin—d. Oct. 4, 1877, Karlsruhe, Ger.), actor, director, manager, translator of Shakespeare into German, and author of the first detailed account of the development of the German theatre, *Geschichte der deutschen Schauspielkunst* (1848; "History of German Dramatic Art").

Nephew of the great Romantic actor Ludwig Devrient, Eduard began his career as an opera singer and in March 1829 sang the part of Christ in the first revival of J.S. Bach's *St. Matthew Passion*. Devrient was an actor and a stage director in Dresden from 1844 until 1852, when he became director of the Hoftheater at Karlsruhe, a post held until 1870.

Reorganizing the court theatre company, Devrient achieved high standards with a repertory of German classics and Shakespeare. The German renderings of Shakespeare that he made, though bowdlerized, proved more suitable to the stage than any previous translations.

Devrient, Emil (b. Sept. 4, 1803, Berlin—d. Aug. 7, 1872, Dresden, Ger.), German actor of the 19th century who gained prominence in youthful heroic parts.

Nephew of the great Romantic actor Ludwig Devrient, he made his debut in Brunswick in 1821. By way of Bremen, Leipzig, and Hamburg, he reached Dresden in 1831, where he remained associated with the court theatre there until his retirement in 1868. His greatest successes were in the title roles of

Goethe's *Torquato Tasso* and *Egmont* and Shakespeare's *Hamlet*, which he played to favourable reviews in London in 1852–53.

Devrient, Karl August (b. April 5, 1797, Berlin—d. Aug. 3, 1872, Hanover, Ger.), German actor who achieved popularity in heroic and character roles such as in the title roles of Friedrich Schiller's *Wallenstein*, Goethe's *Faust*, and Shakespeare's *King Lear*.

Nephew of the great Romantic actor Ludwig Devrient, he began his career in 1819 in Brunswick. From 1821 to 1835 he acted in Dresden, where he married his first wife, the singer Wilhelmine Schröder-Devrient. Karlsruhe (1835–39) was the stepping-stone to Hanover, where he remained for the rest of his life, achieving his greatest triumphs.

Devrient, Ludwig (b. Dec. 15, 1784, Berlin—d. Dec. 30, 1832, Berlin), greatest and most original actor of the Romantic period in Germany, whose temperament, characterizations, and life invite comparison with his English contemporary Edmund Kean. His characterizations conformed to no existing school of acting and owed nothing to any previous performer.

Born to a family of wholesale drapers, Devrient refused to work in his father's business and ran away from home several times. On one occasion he joined the army. When he decided to become an actor, he appeared under an assumed name so as not to embarrass his parents further. He served his apprenticeship with a provincial company in Thuringia, later appearing at the court theatre in Dessau, where he developed his talent for character parts. In 1809 he joined the city theatre at Breslau, where he achieved artistic maturity. When the actor and dramatist August Wilhelm Iffland saw him there, he was struck with his genius and helped him obtain a position with the company of the Royal Court Theatre in Berlin; he made his debut there in 1814 as Franz Moor in Friedrich Schiller's *Die Räuber* (*The Robbers*).

In 1816 Devrient was appointed stage manager but only for comedy and was given comedy roles only. Preferring tragedy, he grew dispirited, drank heavily, and as the years passed became ill and crippled with gout. In 1828, in an appearance at the Vienna Burgtheater, he recovered his spirit and performed as of old. The last few years of his life in Berlin, however, were years of dissipation; he was only 48 years old at the time of his death. His greatest roles were Franz Moor and Shakespearean parts, including Shylock, King Lear, Richard III, and Falstaff. His nephews, Karl August, Eduard, and Emil, along with Eduard's son Otto and Karl's son Max, also made important contributions to the German stage.

Devrient, Max (b. Dec. 12, 1857, Hanover, Hannover—d. June 13, 1929, Chur, Switz.), German actor who excelled in tragic roles, particularly in the plays of Goethe, Schiller, and Shakespeare, but who was also much admired in comedy, especially as Petruchio in Shakespeare's *Taming of the Shrew*.

Grandnephew of the great Romantic actor Ludwig Devrient and son of the noted character actor Karl August Devrient, Max made his debut in 1878 in Dresden as Bertrand in Friedrich Schiller's play *Die Jungfrau von Orleans*. Subsequently he toured extensively throughout Germany. In 1882 he made his first appearance with the famed Vienna Burgtheater in Schiller's drama *Die Räuber*, remaining with the company for many years. From 1920 he directed.

Devrient, Otto (b. Oct. 3, 1838, Berlin—d. July 23, 1894, Stettin, Ger.), German actor, director, producer, and playwright.

Grandnephew of the great Romantic actor Ludwig Devrient, Otto was trained by his father, Eduard Devrient, who was a director, a

translator of Shakespeare, and a stage historian. His early engagements included Karlsruhe, Stuttgart, Berlin, and Leipzig. In 1863 he returned to Karlsruhe to direct, and 10 years later he went to the Weimar Court Theatre, where in 1876 he played Mephistopheles in his own production of Goethe's *Faust*, directing it on a three-level stage. Subsequently he served as stage director in Mannheim and Frankfurt. In 1883 he wrote and staged a Passion play at Jena for a festival in honour of Martin Luther. In 1884 he moved to Oldenburg as a director and, except for a season in Berlin, remained there until his death. He also wrote several tragedies.

dew, deposit of waterdrops formed at night by the condensation of water vapour from the air onto the surfaces of objects freely exposed to the sky. It forms on clear nights when the air is calm or, preferably, when the wind is light. If the temperature of the surface is below the freezing point of water, the deposit takes the shape of hoarfrost (*see* frost). Dew forms on clear nights because on such nights freely exposed surfaces lose heat to the sky by radiation. Unless this loss is offset by an efficient conduction of heat from the interior of the object, the surface will cool. Most objects, including grass blades, leaves, and petals, are much better radiators than air and, as a result, are usually colder at night than is the air. The cold surface cools the air in its vicinity, and, if the air contains sufficient atmospheric humidity, it may cool below its dew point. When this happens, water vapour will condense out of the air onto the surface.

The formation of dew is sustained by the diffusion of water vapour. Regarding the vertical diffusion of water vapour over soils carrying vegetation, there are two possible situations. First, there is the downward movement of water vapour from the atmosphere, which occurs when the water vapour content of the air increases with height. Second, there is the upward movement of water vapour, which occurs when the soil surface temperature is higher than that of the leaves. Accordingly, dew may be classified (1) as formed when water vapour diffuses downward in the air and (2) as formed from water vapour diffusing from the underlying soil surface. The name dewfall is proper to (1), and dew arising from (2) may be called distillation.

There have been various attempts to measure dew. Among the various instruments are R. Leick's porous gypsum plates and S. Duvdevani's dew gauge, consisting of a wooden slab treated with paint. To determine the amount of dew, Leick's plates are weighed, whereas Duvdevani's gauge involves the use of an optical dew scale. Other investigators developed recording dew balances whose surface and exposure conform with the surrounding surface as far as possible. It is by means of such dew balances that one can best observe the phenomenon of distillation: on some occasions no gain in weight or even some loss in weight may be recorded despite the fact that dew had formed on the leaves. Clearly, this dew must be attributed to the diffusion of water vapour from one part of the weighed system to another; *i.e.*, from soil to leaves.

The amount of dew formed on plants is not well known. It would appear that during dew nights the amounts vary from very small quantities to about 0.02 inch (0.51 millimetre). G. Hofmann (*Die Thermodynamik der Taubildung*, 1955) estimated that the maximum possible amount is about 0.03 in. for a 10-hour night, but such amounts would occur only under exceptional circumstances. Total annual dew precipitation may lie between about 0.5 in. in cold climates and in nearly arid warm climates, to about 3 in. in semihumid warm climates. Because dew produced by distillation from the soil cannot be regarded as a gain of moisture, not all of the

annual dew may be significant from a hydrological point of view. In some desert areas and semiarid regions the net gain may be a substantial fraction of the rainfall, however, and dew may be the principal moisture source for plants and animals. Under such conditions, it also may assume an important role in some aspects of rock weathering. From the biological viewpoint, the usefulness of dew is doubtful, as dew may stimulate the growth of fungi harmful to plants.

dewan: see *divan*.

Dewantoro, Ki Hadjar, original name RADEN MAS (LORD) SUWARDI SURJANINGRAT (b. May 8, 1889, Jogjakarta, Java, Dutch East Indies [now Indonesia])—d. April 26, 1959), founder of the Taman Siswa (literally "Garden of Students") school system, an influential and widespread network of schools that encouraged modernization but also promoted indigenous Indonesian culture.

Dewantoro was born into a noble family of Jogjakarta and attended a Dutch-sponsored medical school but failed to complete the course. Active in the nationalist cause, he belonged to a faction favouring direct action and the use of Western methods to destroy the power of the Dutch. He was also a member of the Bandung chapter of Sarekat Islām ("Islamic Association") and a founder of the Socialist Indische Partij ("Indies Party"). An article he wrote during this period, "If I Were a Netherlander," published in the *Indische Partij's De Express*, led to his exile to The Netherlands between 1913 and 1918.

In The Netherlands he became converted to the idea of using Indonesian cultural traditions to cope with the problems posed by Dutch colonial rule. He felt that education was the best means to strengthen Indonesians, and he was deeply influenced by the progressive theories of the Italian educational reformer Maria Montessori and by the Indian poet and philosopher Rabindranath Tagore. The first Taman Siswa schools were established in Java in July 1922. Instruction, carried on informally, emphasized traditional skills and values of Javanese life, particularly music and dance. Western subjects were taught, too, in order to help students cope with the demands of modern life. Overcoming initial official hostility, the Taman Siswa schools had spread throughout the archipelago and were by the late 1930s subsidized by the Dutch colonial government. Based on traditional Javanese concepts, the Taman Siswa schools appealed primarily to those segments of Indonesian society termed *abangan*, in which the Islām faith is less deeply entrenched. Dewantoro continued his leadership of Taman Siswa after the war and upon his death was acclaimed a national hero.

A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume

Dewar, Sir James (b. Sept. 20, 1842, Kincardine-on-Forth, Scot.—d. March 27, 1923, London, Eng.), British chemist and physicist whose study of low-temperature phenomena entailed the use of a double-walled vacuum flask of his own design which has been named for him.

Educated at the University of Edinburgh, Dewar became a professor at the University of Cambridge (1875) and at the Royal Institution of Great Britain, London (1877), holding both posts throughout his life.

Dewar developed structural formulas for benzene (1867), did research in spectroscopy for more than 25 years, and by 1891 had constructed a machine for producing liquid oxygen in quantity. About 1892 he conceived the idea of using vacuum-jacketed vessels for the storage of low-temperature liquid gases, and the resulting device proved so efficient in

preventing the influx of external heat that it became an essential tool in low-temperature scientific work. The principle of the Dewar flask has also been used extensively in the common thermos bottle. Dewar was subsequently the first to liquefy hydrogen gas (1898) and to solidify it (1899). He was knighted in 1904. His discovery (1905) that cooled charcoal can be used to help create high vacuums later proved useful in atomic physics. With Sir Frederick Augustus Abel he developed cordite, an explosive.

Dewās, city, western Madhya Pradesh state, central India. It is located on the Mālwa Plateau at the foot of the conical Chamunda Hill, which rises to a Devīvaśīnī shrine. Jaina and Hindu temple ruins lie just south of the

Devīvaśīnī shrine atop Chamunda Hill, Dewās, Madhya Pradesh, India

Baldev—Shostal Assoc

city, in Nagara. The surrounding area consists chiefly of level plains of the Mālwa Plateau, watered by the Narmada, Sipra, and Kālī Sindh rivers. Wheat, sorghum, rice, cotton, and oilseeds are the chief crops.

Dewās is a major road junction and agricultural trade centre. Cotton and flour milling, handloom weaving, and soap manufacture are the city's chief industries. Dewās, formerly the joint capital of Dewās Senior and Junior princely states, has a musical academy and a government college of education affiliated with Vikram University.

Dewās was founded by two Panwār Marāṭhā brothers who entered Mālwa in 1728. From 1841 the senior and junior branches of the family ruled their own portions independently as part of the British Central India Agency. Both states merged with Madhya Pradesh in 1956. Pop. (1991 prelim.) city, 163,699.

dewberry, any blackberry of the genus *Rubus* (family Rosaceae) so lacking woody fibre in the stems that it trails along the ground. In the eastern and southern United States, several trailing native species of *Rubus*, especially *R. flagellaris*, *R. baileyanus*, *R. hispidus*, *R. enslenii*, and *R. trivialis*, produce excellent fruits. Some varieties, especially *Lucretia*, are cultivated. See also blackberry.

Dewey, George (b. Dec. 26, 1837, Montpelier, Vt., U.S.—d. Jan. 16, 1917, Washington, D.C.), U.S. naval commander who defeated the Spanish fleet at the Battle of Manila Bay during the Spanish-American War (1898).

George Dewey
Brown Brothers

A graduate of the U.S. Naval Academy at Annapolis, Md., in 1858, Dewey was commissioned a lieutenant three years later. In the U.S. Civil War (1861–65), he served with Union naval forces in the battles of New Orleans (1862) and Port Hudson and Donaldsonville, La. (1863). In 1864–65 he served in the North Atlantic blockading squadron.

After receiving periodic promotions, Dewey was assigned (1897), at his own request, to the U.S. Asiatic squadron. Anticipating war with Spain, he undertook an intensive study of the Spanish-owned Philippine Islands and prepared his fleet for battle. When war did break out (April 1898), he sailed from Hong Kong to the Philippines, and on the evening of April 30 his squadron entered Manila Bay, where the Spanish fleet was anchored near Cavite Island. Dewey, with his four cruisers and two gunboats in line, opened fire the following morning shortly before 6:00 AM with the now-famous command, "You may fire when you are ready, Gridley." American naval gunfire had sunk or destroyed most of the Spanish warships by the time the squadron withdrew about 7:35 AM. The American ships resumed the action a few hours later to reduce the remaining Spanish ships and the shore batteries around Cavite. The Spaniards offered little effective resistance, and Dewey was able to defeat them without the loss of a single man. His victory resulted in the acquisition of the Philippines by the United States and signaled the expansion of that country's power into the western Pacific.

Dewey subsequently returned home and was welcomed in New York City with a great ovation. In March 1899 the U.S. Congress created for him the rank of admiral of the navy, the highest rank ever held by a U.S. naval officer. For the last 17 years of his life he served as president of the general board of the navy.

Dewey, John (b. Oct. 20, 1859, Burlington, Vt., U.S.—d. June 1, 1952, New York, N.Y.), American philosopher and educator who was one of the founders of the philosophical school of pragmatism, a pioneer in functional psychology, and a leader of the progressive movement in education in the United States.

John Dewey
EB Inc

Early life. The son of a grocer in Vermont, Dewey attended the public schools of Burlington and there entered the University of Vermont. After graduating from the university in 1879, Dewey taught high school for three years. In the fall of 1882 he entered Johns Hopkins University, in Baltimore, for advanced study in philosophy. There he came under the in-

fluence of George Sylvester Morris, who was a leading exponent of Neo-Hegelianism, a revival of the thought of the early-19th-century German philosopher Hegel. Dewey found in this philosophy, with its emphasis on the spiritual and organic nature of the universe, what he had been vaguely groping for, and he eagerly embraced it.

After being awarded the Ph.D. degree by Johns Hopkins University in 1884, Dewey, in the fall of that year, went to the University of Michigan, where, at the urging of Morris, he had been appointed an instructor in philosophy and psychology. With the exception of the academic year 1888–89, when he served as professor of philosophy at the University of Minnesota, Dewey spent the next 10 years at Michigan. During this time his philosophical endeavours were devoted mainly to an intensive study of Hegel and the British Neo-Hegelians and to the new experimental physiological psychology then being advanced in the United States by G. Stanley Hall and William James.

Dewey's interest in education began during his years at Michigan. His readings and observations revealed that most schools were proceeding along lines set by early traditions and were failing to adjust to the latest findings of child psychology and to the needs of a changing democratic social order. The search for a philosophy of education that would remedy these defects became a major concern for Dewey and added a new dimension to his thinking.

Philosophical thought. Dewey left Michigan in 1894 to become professor of philosophy and chairman of the department of philosophy, psychology, and pedagogy at the University of Chicago. Dewey's achievements there brought him national fame. The increasing dominance of evolutionary biology and psychology in his thinking led him to abandon the Hegelian theory of ideas, which views them as somehow mirroring the rational order of the universe, and to accept instead an instrumentalist theory of knowledge, which conceives of ideas as tools or instruments in the solution of problems encountered in the environment. These same disciplines contributed somewhat later to his rejection of the Hegelian notion of an Absolute Mind manifesting itself as a rationally structured, material universe and as realizing its goals through a dialectic of ideas. Dewey found more acceptable a theory of reality holding that nature, as encountered in scientific and ordinary experience, is the ultimate reality and that man is a product of nature who finds his meaning and goals in life here and now.

Since these doctrines, which were to remain at the centre of all of Dewey's future philosophizing, also furnished the framework in which Dewey's colleagues in the department carried on their research, a distinct school of philosophy was in operation. This was recognized by William James in 1903, when a collection of essays written by Dewey and seven of his associates in the department, *Studies in Logical Theory*, appeared. James hailed the book enthusiastically and declared that with its publication a new school of philosophy, the Chicago school, had made its appearance.

Dewey's philosophical orientation has been labeled a form of pragmatism, though Dewey himself seemed to favour the term "instrumentalism," or "experimentalism." William James's *The Principles of Psychology* early stimulated Dewey's rethinking of logic and ethics by directing his attention to the practical function of ideas and concepts, but Dewey and the Chicago school of pragmatists went farther than James had gone in that they conceived of ideas as instruments for transforming the uneasiness connected with the experience

of having a problem into the satisfaction of some resolution or clarification of it.

Dewey's preferred mode of inquiry was scientific investigation; he thought the experimental methods of modern science provided the most promising approach to social and ethical as well as scientific problems. He rejected the idea of a fixed and immutable moral law derivable from consideration of the essential nature of man, since such a traditional philosophical method denied the potential application and promise of newer empirical and scientific methods.

Dewey developed from these views a philosophical ground for democracy and liberalism. He conceived of democracy not as a mere form of government, but rather as a mode of association which provides the members of a society with the opportunity for maximum experimentation and personal growth. The ideal society, for Dewey, was one that provided the conditions for ever enlarging the experience of all its members.

Dewey's contributions to psychology were also noteworthy. Many of the articles he wrote at that time are now accepted as classics in psychological literature and assure him a secure place in the history of psychology. Most significant is the essay "The Reflex Arc Concept in Psychology," which is generally taken to mark the beginnings of functional psychology—*i.e.*, one that focuses on the total organism in its endeavours to adjust to the environment.

Educational theory and practice. Dewey's work in philosophy and psychology was largely centred in his major interest, educational reform. In formulating educational criteria and aims, he drew heavily on the insights into learning offered by contemporary psychology as applied to children. He viewed thought and learning as a process of inquiry starting from doubt or uncertainty and spurred by the desire to resolve practical frictions or relieve strain and tension. Education must therefore begin with experience, which has as its aim growth and the achievement of maturity.

Dewey's writings on education, notably his *The School and Society* (1899) and *The Child and the Curriculum* (1902), presented and defended what were to remain the chief underlying tenets of the philosophy of education he originated. These tenets were that the educational process must begin with and build upon the interests of the child; that it must provide opportunity for the interplay of thinking and doing in the child's classroom experience; that the teacher should be a guide and coworker with the pupils, rather than a taskmaster assigning a fixed set of lessons and recitations; and that the school's goal is the growth of the child in all aspects of its being.

Among the results of Dewey's administrative efforts were the establishment of an independent department of pedagogy and of the University of Chicago's Laboratory Schools, in which the educational theories and practices suggested by psychology and philosophy could be tested. The Laboratory Schools, which began operation in 1896, attracted wide attention and enhanced the reputation of the University of Chicago as a foremost centre of progressive educational thought. Dewey headed the Laboratory Schools until 1904.

Dewey's ideas and proposals strongly affected educational theory and practice in the United States. Aspects of his views were seized upon by the "progressive movement" in education, which stressed the student-centred rather than the subject-centred school, education through activity rather than through formal learning, and laboratory, workshop, or occupational education rather than the mastery of traditional subjects. But though Dewey's own faith in progressive education never wavered, he came to realize that the zeal of his followers introduced a number of excesses and defects into progressive education. Indeed, in *Experience*

and *Education* (1938) he sharply criticized educators who sought merely to interest or amuse students, disregarded organized subject matter in favour of mere activity on the part of students, and were content with mere vocational training.

During the last two decades of Dewey's life, his philosophy of education was the target of numerous and widespread attacks. Progressive educational practices were blamed for the failure of some American school systems to train pupils adequately in the liberal arts and for their neglect of such basic subjects as mathematics and science. Furthermore, critics blamed Dewey and his progressive ideas for what the former viewed as an insufficient emphasis on discipline in the schools.

Career at Columbia University. Disagreements between President William Rainey Harper of the University of Chicago and Dewey led, in 1904, to Dewey's resignation of his posts and to his acceptance of a professorship of philosophy at Columbia University in New York City. Dewey was associated with Columbia for 47 years, first as professor and then as professor emeritus of philosophy. During his 25 years of active teaching, his fame and the significance of what he had to say attracted thousands of students from home and abroad to his classes, and he became one of the most widely known and influential teachers in America.

Dewey's scholarly output at Columbia was enormous; one bibliography devotes approximately 125 pages to listing the titles of his publications during these years. His thought covered a wide range of topics, including logic and theory of knowledge, psychology, education, social philosophy, fine arts, and religion. Major works dealing with each of these fields appeared over the years and clearly established Dewey as the foremost philosopher in America and as one of the nation's most productive scholars. His *Experience and Nature*, published in 1925, brings together in a systematic way the more important aspects of his philosophy and is generally regarded as his magnum opus.

His interest in current affairs prompted Dewey to contribute regularly to liberal periodicals, especially *The New Republic*. His articles focused on domestic, foreign, and international developments and were designed to reach a wide reading public. Because of his skill in analyzing and interpreting events, he soon was rated as among the best of American commentators and social critics.

Dewey also gave his time and energy to the support of organizations and causes in which he believed. In 1915 he became one of the founders and the first president of the American Association of University Professors, and the next year he became a charter member of the first teachers' union in New York City. He helped found the New School for Social Research in 1919 and the University-in-Exile in 1933, established for scholars being persecuted in countries under totalitarian regimes. In the 1920s he visited Japan, Mexico, and the Soviet Union to study educational methods in those countries. In 1937, at age 78, he headed a commission of inquiry that went to Mexico City to hear Leon Trotsky's rebuttal of the charges made against him in the Moscow show trials of 1936 and 1937.

Dewey retired from the Columbia faculty in 1930, after which he concentrated on public affairs while continuing to write. Among his books on psychology and philosophy are *Psychology* (1887), *Ethics* (cowritten with James Tufts; 1908), *Reconstruction in Philosophy* (1920), *Human Nature and Conduct* (1922), *The Quest for Certainty* (1929), *Art as Experience* (1934), *Logic, the Theory of Inquiry* (1938), and *Freedom and Culture* (1939). His chief later writings on education are *Democracy and Education* (1916) and *Experience and Education* (1938). (G.Dy./C.H.F.)

BIBLIOGRAPHY. George Dykhuizen, *The Life and Mind of John Dewey* (1973), provides a detailed account of Dewey's life and thought; it may be supplemented by Steven C. Rockefeller, *John Dewey: Religious Faith and Democratic Humanism* (1991), an intellectual biography. Studies focusing on his thought include Sidney Hook, *John Dewey: An Intellectual Portrait* (1939, reprinted 1971), a very readable and authoritative account of the several aspects of Dewey's philosophy; George R. Geiger, *John Dewey in Perspective* (1958, reprinted 1974), an exposition of Dewey's philosophy in the light of the misunderstandings and distortions which have centred about it; Richard J. Bernstein, *John Dewey* (1966, reprinted 1981), an illuminating study of the leading ideas of Dewey's philosophy; Jo Ann Boydston (ed.), *Guide to the Works of John Dewey* (1970), a collection of essays by Deweyan scholars each introducing the reader to a particular area of Dewey's thought; Neil Coughlan, *Young John Dewey: An Essay in American Intellectual History* (1975), a study of his early intellectual development; Steven M. Cahn (ed.), *New Studies in the Philosophy of John Dewey* (1977), on various aspects of his thought; Gary Bullert, *The Politics of John Dewey* (1983), on his political activism; and Paul Arthur Schilpp and Lewis Edwin Hahn (eds.), *The Philosophy of John Dewey*, 3rd ed. (1989), which contains, in addition to a biographical sketch of Dewey, a collection of essays by different authors (each a critical study of some aspect of Dewey's philosophy), a concluding essay by Dewey in response to his critics, and a bibliography of Dewey's writings.

Dewey, Melvil (b. Dec. 10, 1851, Adams Center, N.Y., U.S.—d. Dec. 26, 1931, Lake Placid, Fla.), American librarian who devised the Dewey Decimal Classification for library cataloging and, probably more than any other individual, was responsible for the development of library science in the United States.

Dewey graduated in 1874 from Amherst College and became acting librarian at that institution. In 1876 he published *A Classification and Subject Index for Cataloguing and Arranging the Books and Pamphlets of a Library*, in which he outlined what became known as the Dewey Decimal Classification. This system was gradually adopted by libraries throughout the English-speaking world. In 1877 Dewey moved to Boston, where, with R.R. Bowker and Frederick Leyoldt, he founded and edited the *Library Journal*. He was also one of the founders of the American Library Association. In 1883 he became librarian of Columbia College, New York City, and there set up the School of Library Economy, the first institution for training librarians in the United States. The school was moved to Albany, N.Y., as the State Library School under his direction.

From 1889 to 1906 he was director of the New York State Library. He also served as

secretary of the State University of New York (1889–1900) and as state director of libraries (1904–06). He completely reorganized the New York state library, making it one of the most efficient in the United States, and established the system of traveling libraries and picture collections.

Dewey, Thomas E., in full THOMAS EDMUND DEWEY (b. March 24, 1902, Owosso, Mich., U.S.—d. March 16, 1971, Bal Harbour, Fla.), vigorous U.S. prosecuting attorney

Thomas E. Dewey, 1944
UPI Complex

whose successful racket-busting career won him three terms as governor of New York (1943–55). A long-time Republican leader, he was his party's presidential nominee in 1944 and 1948 but lost in both elections.

Dewey graduated from the University of Michigan in 1923 and received his law degree from Columbia University in 1925. Admitted to the New York bar in 1926, Dewey launched his government career five years later as chief assistant to the U.S. attorney for the southern district of the state. Between 1935 and 1937 he garnered national attention as special prosecutor in an investigation of organized crime in New York; he obtained 72 convictions out of 73 prosecutions of long-established racketeers. Elected district attorney in 1937, Dewey continued to impress the electorate with his legal acumen and with his personal drive and integrity.

Although unsuccessful in his first bid for governor (1938), Dewey was elected for three successive terms beginning in 1942. In office he earned a reputation for political moderation and administrative efficiency, putting the state on a pay-as-you-go basis for capital building, reorganizing departments, and establishing the first state agency to eliminate discrimination in employment.

As Republican nominee for president in 1944, Dewey was neither expected nor able to overcome the enormous wartime prestige of the incumbent, President Franklin D. Roosevelt. The pollsters flatly predicted victory for his candidacy in 1948, however, though the political picture was confused by the entrance of two minority extremist factions—the Progressives and the States' Rights (Dixiecrat) Party. Waging a noncommittal campaign purposely designed to avoid offending any segment of the electorate, Dewey was unexpectedly defeated by President Harry S. Truman, who surprisingly retained the loyalty of both farm and labour circles.

As a leader of the eastern Republicans at the 1952 national convention, he played a key role in the nominations of General Dwight D. Eisenhower for president and Senator Richard M. Nixon for vice president. At the end of his third term as governor (1955), Dewey returned to a lucrative private law practice. He remained a close adviser to Republican administrations but thought his age precluded acceptance of an offer by President Nixon in 1968 to serve as chief justice of the U.S. Supreme Court.

Dewey Decimal Classification, also called DEWEY DECIMAL SYSTEM, system for organizing the contents of a library based on

the division of all knowledge into 10 groups, with each group assigned 100 numbers. The 10 main groups are: 000–099, general works; 100–199, philosophy and psychology; 200–299, religion; 300–399, social sciences; 400–499, language; 500–599, natural sciences and mathematics; 600–699, technology; 700–799, the arts; 800–899, literature and rhetoric; and 900–999, history, biography, and geography. These 10 main groups are in turn subdivided again and again to provide more specific subject groups. Within each main group the principal subseries are divided by 10; e.g., the history of Europe is placed in the 940s. Further subdivisions eventually extend into decimal numbers; e.g., the history of England is placed under 942.06, and the history of the English Commonwealth at 942.063.

Based on W.T. Harris' classification for the St. Louis Public Library, the Dewey system was first formulated by the American librarian Melvil Dewey in 1873 for application in the Amherst College Library. It was first published in 1876, and the 20th edition of the system had been published by the late 20th century.

The Dewey system's numerical classification provides a shorthand identification and location tool. The notation lends itself to memory through the constant repetition of a standard pattern (area arrangement, different numbers for particular languages), through parallel subject developments (each book of the Bible given the same development as the Bible as a whole), and through patterned repetition of standard subdivisions (theory, study and teaching, history, geography, etc.). To distinguish works within a group and to expedite retrieval, many libraries add a book number created from the Cutter, or Cutter-Sanborn, Tables, which provide further specifications for author and genre.

Because an abridged as well as a full schedule (or classificatory guide) of the system has been developed, the Dewey Decimal Classification is adaptable to libraries of various sizes. The Index to the Dewey Decimal systems, a relative one (i.e., one having cross-references), arranges all topics expressed or implied, with every synonym in alphabetical order.

The names Dewey Decimal Classification and Dewey (when referring to the former) are trademarks of the Lake Placid Education Foundation.

Dewhurst, Colleen (b. June 3, 1924, Montreal, Que., Can.—d. Aug. 22, 1991, South Salem, N.Y., U.S.), American actress who was the leading Broadway interpreter of the plays of Eugene O'Neill in the second half of the 20th century.

Colleen Dewhurst as Kate in *The Taming of the Shrew*, 1956

Melvil Dewey, detail of a portrait by an unknown artist; in the collection of the New York State Library, Albany

By courtesy of the New York State Library, Albany

The daughter of a professional hockey player, Dewhurst eventually moved to New York City, where she studied acting at the American Academy of Dramatic Arts and privately under Joseph Anthony and Harold Clurman. She made her Broadway debut in a minor role in O'Neill's *Desire Under the Elms* (1952) and first gained notice as Kate in the 1956 New York Shakespeare Festival's production of *The Taming of the Shrew*. In 1958 she appeared with George C. Scott in *Children of Darkness*, and she acted with him in the title roles of *Antony and Cleopatra* the following year. She and Scott were subsequently married to and divorced from each other twice.

Dewhurst's most notable roles in O'Neill plays were Abbie Putnam in *Desire Under the Elms* (1963), Sara Melody in *More Stately Mansions* (1967), Christine Mannon in *Mourning Becomes Electra* (1972), Josie Hogan in *A Moon for the Misbegotten* (1973), and Mary Tyrone in *Long Day's Journey Into Night* (1988). Among her other stage roles were those in *The Ballad of the Sad Cafe* (1963) and *You Can't Take It With You* (1983).

Dewhurst also appeared in motion pictures and in numerous plays filmed for television. She was president of the Actors' Equity Association, a union of professional actors, from 1985 to 1991.

Dewi, SAINT: see David, Saint.

DeWitt, Lydia Maria Adams, née Adams (b. Feb. 1, 1859, Flint, Mich., U.S.—d. March 10, 1928, Winter, Texas), American experimental pathologist and investigator of the chemotherapy of tuberculosis.

In 1878 she married Alton D. DeWitt, a teacher. Lydia DeWitt earned a medical degree at the University of Michigan in 1898 and taught anatomy there until 1908. She subsequently taught at Michigan State University (1908–10), Washington University (1910–12), and the University of Chicago (1912–26).

DeWitt is best known for her studies of the pathology of tuberculosis. She analyzed the linkages of dyes and toxic metals for the potential treatment of tuberculosis, and her investigations set the standard for later studies that led to the successful treatment of the disease. She also conducted influential investigations on the anatomy of the nervous system and on public health practices.

Her numerous publications include the coauthorship of the studies "Chemotherapy of Tuberculosis" (1893) and *The Chemistry of Tuberculosis* (1923).

A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume

Dewsbury, locality in Kirklees district, metropolitan area of West Yorkshire, Eng. It lies along the River Calder, 9 miles (14 km) south-southwest of Leeds. Dewsbury (which was mentioned in Domesday Book of 1086) had a woolen industry as early as the 13th century, but there was no great expansion until the Industrial Revolution, when the town became the natural centre of a heavy woolen district. The chief industries are weaving, coal mining, and engineering.

There is a tradition that Paulinus, the first archbishop of York, preached in AD 627 at Dewsbury, which had in Saxon times a parish of more than 400 square miles (1,000 square km) in area. Another tradition holds that Robin Hood died and was buried in the extensive park at Kirklees, where there are the remains of a 12th-century Cistercian convent. The parish church of All Saints, mostly rebuilt in the 18th century, retains 9th-century

Anglo-Saxon carvings. Inc. 1862. Pop. (1991) urban area, 50,168.

Dexippus, Publius Herennius (b. c. 210—d. after 270), Roman historian and Athenian statesman, one of the principal authorities for the history of the mid-3rd century AD.

The *Bibliotheca*, a 9th-century encyclopaedia by Photius, patriarch of Constantinople, credits Dexippus with three major works: a four-book history of the *diadochoi* (successors) of Alexander the Great, a history of the struggle of Rome against the Goths after AD 238, and a 12-book annalistic chronicle from legendary times to AD 270. Although none of these survive, numerous fragments have been recognized in the compilations of later historians. Several Athenian inscriptions attest to the high public offices held by Dexippus, his father, and his children. He himself relates (in fragment 28) how he rallied about 2,000 of his fellow citizens to repel a Gothic attack on Athens, probably about 267.

dextromethorphan, also called *d-3-METHOXY-N-METHYLMORPHINAN*, synthetic drug related to morphine and used in medicine as a cough suppressant. The hydrobromide salt of dextromethorphan is administered orally in syrups and tablets. It acts upon the central nervous system to suppress the cough reflex. It does not produce addiction or central depression, as do a number of other morphine derivatives, and it has no analgesic effect.

Dextromethorphan hydrobromide occurs as white crystals or a white crystalline powder, soluble in water, alcohol, and chloroform.

dextrose (sugar): see glucose.

dey, in the Ottoman provinces of Algiers and Tunis, an honorary title conferred upon exceptionally able corsair leaders; also, a lower rank of officer in the Janissaries. In late 16th-century Tunis, a dey commanded the army and eventually was in sole control of the state, but by 1705 the title had disappeared from official lists. The head of the Algerian regency, elected by fellow Janissary officers (from 1689), was titled dey, and, though his family life was restricted to prevent succession claims and he was confined to Algiers, he had virtually absolute power; 30 such deys ruled Algiers in succession between 1671 and 1830.

Deyssel, Lodewijk van, pseudonym of KAREL JOAN LODEWIJK ALBERDINGK THIJM (b. Sept. 22, 1864, Amsterdam, Neth.—d. Jan. 26, 1952, Haarlem), leading Dutch writer and critic of the late 19th and early 20th centuries.

The son of J.A. Alberdingk Thijm (who promoted a Roman Catholic cultural revival in The Netherlands), he joined the largely agnostic individualistic group associated with the avant-garde literary magazine *De nieuwe gids* ("The New Guide"). His passionate critical writings were published as *Verzamelde opstellen*, 11 vol. (1894–1911; "Collected Essays"). He began writing as an admirer of Émile Zola and published a naturalistic novel, *Een liefde* (1887; "A Love Affair"). Later he abandoned naturalism and wrote highly personal impressionistic prose and clever, somewhat overwrought "prose-verses." A sensitive artist with great powers of observation and a keen eye for detail, he was a powerful influence on Dutch literature, as both an original and critical writer, for many years.

Dez Dam, formerly PAHLAVI DAM, an arch dam across the Dez River in Iran, completed in 1963. The dam is 666 feet (203 m) high, 696 feet (212 m) wide at the crest, and has a volume of 647,000 cubic yards (495,000 cubic m). Until the late 1960s it was the largest Iranian development scheme.

Dezfūl, also spelled DIZFUL, city, southwestern Iran. It lies on the high left bank of the Dez River, 469 feet (143 m) in elevation, close to the foothills of the Zagros Mountains.

Dezfūl on the left bank of the Dez River, Iran
Fred J. Maroon—Photo Researchers

The name, meaning Dez Bridge, is derived from the imposing bridge, 1,345 feet (410 m) long, that spans the river and was allegedly erected by King Shapur II (died 379). The city witnessed riots by the local people in 1978, prior to the Iranian Revolution. Iraqi planes attacked Dezfūl during the Iran-Iraq War.

Dezfūl is the principal winter market for the Lorestān (Luristan) region's nomadic population; it connects by road with the highland and with Ahvāz. The Trans-Iranian Railway stops on the other side of the river, and there is an airfield. The great Dez Dam, 20 miles (32 km) upstream, was designed to provide abundant power and to increase irrigation. Pop. (1996) 202,639.

Dezhev, Cape: see Dezhnyov, Cape.

Dezhnyov, Cape, also spelled DEZHNEV, Russian MYS DEZHNYOVA, English EAST CAPE, cape, extreme eastern Russia. Cape Dezhnyov is the easternmost point of the Chukchi Peninsula and of the entire Eurasian landmass. It is separated from Cape Prince of Wales in Alaska by the Bering Strait. The Russian name was given in 1879 in honour of a Russian explorer S.i. Dezhnyov, who with F.A. Popov first rounded it in 1648.

Dezhnyov, Semyon Ivanov, Dezhnyov also spelled DEZHNEV (b. c. 1605, Veliky Ustyug, Russia—d. early 1673, Moscow), Russian explorer, the first European known to have sailed through the Bering Strait.

Dezhnyov served as a Cossack in Siberia, where he traveled a great deal in the north beginning in the early 1640s. In 1648 he sailed from the Kolyma River eastward to the Bering Strait, rounding the northeast tip of Asia (now called Cape Dezhnyov) and reaching the Anadyr River. He thus proved the separation of Asia and North America, but his report lay buried in the archives at Yakutsk until the German historian Gerhard Friedrich Müller found it in 1736, so the discovery was not known about until nearly a century had passed and after Vitus Bering and others had explored the area.

Dezhou (China): see Te-chou.

Dga'-ldan, also spelled GALDAN (b. 1644?, Central Asia—d. May 3, 1697, East Turkistan [now Sinkiang, China]), leader of the Dzungar tribes of Mongols (reigned 1676–97). He conquered an empire that included Tibet in the southwest and ranged across Central Asia to the borders of Russia in the northeast.

Dga'-ldan was a descendant of Esen, a Mongol chieftain who harassed the northern border of China during the 15th century, and

his father was a powerful Dzungar chief. As a younger son, Dga'-Idan was sent to Tibet, a Dzungar protectorate since 1636, where he was educated to be a Buddhist lama. In 1671, however, when his brother, who had become the tribal leader, was murdered, Dga'-Idan returned to Turkistan to seek vengeance. Because of his great military ability and his prestige as a lama, he rapidly gained authority over the other Dzungar chiefs. He avenged his brother's death and then occupied all of East Turkistan (now in Uygur Autonomous Region of Sinkiang), subduing the Muslim population there. He then conquered Outer Mongolia (now the Mongolian People's Republic), expelling the Khalkha Mongols from their land.

In 1690 Dga'-Idan led his armies toward Peking, the Chinese capital, but the Chinese forces stopped him short of his destination. Finally in 1696, after several years of indecisive fighting, the emperor K'ang-hsi of China, allied with the Khalkhans, personally led some 80,000 troops across Mongolia in pursuit of Dga'-Idan. K'ang-hsi's use of Western artillery, made under instruction from Jesuit missionaries, crushed Dga'-Idan at Dzuunmod, near present-day Ulaanbaatar. The battle signaled the beginning of Chinese domination over the Central Asian nomads who had harassed the empire for a millennium.

Although his wife and son were killed, Dga'-Idan refused to surrender. He fled with a small band of followers to the Altai Mountains. When news came the next year that the emperor was leading another expedition against him, Dga'-Idan reportedly poisoned himself.

Dge-lugs-pa, also spelled **GELUKPA** (Tibetan: "Model of Virtue"), also called **YELLOW HAT SECT**, since the 17th century, the predominant Buddhist order in Tibet and the sect of the Dalai and Pañchen lamas.

The Dge-lugs-pa sect was founded in the late 14th century by Tsong-kha-pa, who was himself a member of the austere Bka'-gdams-pa school. Tsong-kha-pa's reforms represented a return to tradition. He enforced strict monastic discipline, restored celibacy and the prohibition of alcohol and meat, established a higher standard of learning for monks, and, while continuing to respect the Vajrayāna tradition of esotericism that was prevalent in Tibet, allowed Tantric and magical rites only in moderation. Three large monasteries were quickly established near Lhasa: at Dga'-Idan (Ganden) in 1409, 'Bras-spungs (Drepung) in 1416, and Se-ra in 1419. The abbots of the 'Bras-spungs monastery first received the title Dalai Lama in 1578, and a period of struggle for the leadership of Tibet followed, principally with the Karma-pa sect. The Dge-lugs-pa eventually appealed to the Mongol chief Güüshi Khan for help, and his defeat in 1642 of the king of Gtsang, who favoured the Karma-pa, secured the temporal authority of Tibet for the Dge-lugs-pa. They continued to rule the country through their leader, the Dalai Lama, until the Chinese communists took over the country in 1950. During a popular revolt at Lhasa in 1959, the Dalai Lama escaped to India. A new Pañchen Lama, installed as a figurehead by the Chinese, was dismissed in 1964.

The name Yellow Hat refers to the distinctive yellow headdress adopted by the Dge-lugs-pa to distinguish themselves from the Karma-pa sect, whose monks wear red hats.

DGI, abbreviation of **DIRECCIÓN GENERAL DE INTELIGENCIA**, the secret intelligence agency of Cuba. The agency was established with the help of the Soviet KGB in 1961, following Fidel Castro's rise to power. The DGI provided Castro with advanced warning of the Bay of Pigs invasion backed by the U.S. Central Intelligence Agency in 1962. The agency is responsible for intelligence, counterintelligence, and disinformation activities inside Cuba and abroad.

DGSE, abbreviation of **DIRECTION GÉNÉRALE DE LA SÉCURITÉ EXTÉRIEURE** ("General Board of External Security"), formerly (1947-81) **SDECE**, or **SERVICE DE DOCUMENTATION EXTÉRIEURE ET DE CONTRE-ESPIONNAGE** ("External Documentation and Counterespionage Service"), secret intelligence and counterintelligence service that operates under the defense ministry of the French government. This agency was established in 1947 to combine under one head a variety of separate agencies, some dating from the time of Napoleon and some from the Free French of World War II. It was independent until the mid-1960s, when the SDECE was discovered to have been involved in the kidnapping and presumed murder of Mehdi Ben Barka, a Moroccan revolutionary living in Paris. Following this scandal, the agency was placed under the control of the defense ministry. It was restructured in 1981. DGSE gathers foreign intelligence and provides internal security. Details of its operations and organization are not made public.

Dhahabī, al-: see **Aḥmad al-Manṣūr**.

Dhahran (Saudi Arabia): see **Zahrān, az-**.

Dhākā, also spelled **DACCA**, city and capital of Bangladesh, located just north of the Burhi Ganga River, a channel of the Dhaleswari, in the south-central part of the country. Its name is said to refer to the dhak tree, once common in the area, or to Dhākésvari ("The Hidden Goddess"), whose shrine is located in the western part of the city.

Dhākā's history can be traced to the 1st millennium AD, but it did not rise to prominence until the 17th century, when it served as the Mughal capital of Bengal province (1608-39 and 1660-1704). It was the centre of a flourishing sea trade, attracting English, French, and Dutch traders.

Historic buildings of the Muslim period include Lāl Bāgh fort (1678) and its tomb of Bibi Parī (d. 1684), wife of a governor of Bengal; the Barā Katrā (great caravansary; 1664); the Chhota Katrā (small caravansary; 1663); and Husayni Dālān (a religious monument of the Shī'ite sect; 1642). Other 17th-century buildings include the Hindu Dhākésvari temple and Tejgaon church, built by the Portuguese. The more than 700 mosques, including Bayt ul-Mukarram, date back to the 15th century.

With the removal of the provincial capital to Murshidābād (1704) and the decline of the muslin industry, Dhākā entered a period of decline. It passed under British control in 1765, was constituted a municipality in 1864, but continued to decay until it was designated capital of Eastern Bengal and Assam province

(1905-12). During the early 20th century Dhākā served as a commercial centre and seat of learning. It became the capital of East Bengal province (1947) and of East Pakistan (1956). Dhākā suffered heavy damage during the war of independence in 1971 but emerged as the capital of Bangladesh.

Together with its river port of Nārāyananj, 10 miles (16 km) south, Dhākā now houses the largest industrial concentration in the country. Traditional products include *jāmdāni* (fine-quality muslin), embroidery, silk, and jewelry.

The city also contains the University of Dhākā (1921) and Jahangirnagar University (1970), numerous affiliated government colleges, an engineering and technology university, a nuclear-science training and research centre, a library, and a museum.

The area around Dhākā consists of a level plain bounded by the Meghna, Padma (Ganges), and Jamuna (Brahmaputra) rivers. The plain is crossed by a network of streams and rivers, the chief being the Dhaleswari, Burhi Ganga, and Lakhya. Important crops are rice, jute, sugarcane, and oilseeds; there is also a government cattle farm. Industries include jute processing and the manufacture of rope, string, baskets, cotton cloth, and boats. The area includes the ancient city of Vikramapur, former capital of the Pāla rulers of Bengal (8th-12th century). Pop. (1991) city, 3,612,850; (1999 est.) urban agglom., 11,726,000.

Dhamār, town, western Yemen, lying in the Yemen Highlands, in a valley 12 miles (19 km) wide between two volcanic peaks at 8,000 feet (2,400 m) above sea level. Although local tradition dates many of the sites in the district to biblical times, the first certain historical mention of Dhamār is by the Arab geographer and philologist Yāqūt (1179-1229), who wrote of its fine public buildings and of the fertility of the surrounding countryside.

Long the principal religious centre of the Zaydi sect of Islām, dominant in Yemen for many centuries, Dhamār was the seat of a renowned madrasah (theological school). As the former capital of the Central, or Dhamār, *liwā'* (province) under the monarchy, it was ruled as an emirate by the princely Al Wazīr family until 1944, when the country's administration was reorganized.

The town is built in two sections, divided by a belt of irrigated market gardens. There are some typical Yemeni multistory houses, but most dwellings are of one-story mud-brick construction; the town also has several

Bayt ul-Mukarram Mosque and shopping mall, Dhākā, Bangladesh
Frederic Ohninger from the Nancy Palmer Agency—EB Inc

fine mosques. Dhamār is a market centre for the surrounding grain-growing countryside and also has some handicraft industries. The area has long been renowned for its horses. Pop. (1986) 47,733.

dhamma (religious concept): *see* dharma.

Dhammapāda (Pāli: "Words of Doctrine," or "Way of Truth"), probably the best-known book in the Pāli Buddhist canon and the most quoted in other Buddhist writings. It is an anthology of basic Buddhist teachings (primarily ethical teachings) in a simple aphoristic style. As the second text in the *Khuddaka Nikāya* ("Short Collection") of the *Sutta Piṭaka* ("Basket of Discourse"), the *Dhammapāda* contains 423 stanzas arranged in 26 chapters. It also appears in somewhat different versions in Prākṛit, Sanskrit, and Chinese, and there are translations in other languages. More than half the verses are excerpted from other canonical texts and include many of the most famous Buddhist sayings; others come from the storehouse of pithy sayings drawn upon by much of Indian literature.

The book is popular in Buddhist countries of both Theravāda and Mahāyāna traditions. In Sri Lanka it has been used for centuries as a manual for novices, and it is said that every monk can recite it from memory.

Dhamtari, town, eastern Chhattisgarh state, central India, just west of the Mahānadi River. The town is a rail-spur terminus and trade centre for agricultural and forest products. Rice and flour milling and shellac manufacture are the chief industries. Dhamtari has an industrial school and two colleges affiliated with Ravishankar University. It was constituted a municipality in 1881. Pop. (1991) 69,400.

Dhānbād, city, eastern Jharkhand state, northeastern India. It lies in the Dāmodar River valley near the Jharia coalfield and is an important agricultural-trade centre. The Indian School of Mines, affiliated with the University of Bihār, and the Central Fuel Research Institute are located there.

The Dāmodar River, which crosses from east to west the region in which Dhānbād is sited, is flanked by irrigation tanks and fields of rice, corn (maize), and oilseeds. The nearby Jharia and Rāniganj coalfields have helped make the region India's leading coal producer. Pop. (1991) 151,789; metropolitan area, 815,005.

Dhanvantari, also spelled DHANWANTARI, in Hindu mythology, the physician of the gods. According to legend, the gods and the demons sought the elixir *amṛta* by churning the milky ocean, and Dhanvantari rose out of the waters bearing a cup filled with the elixir. The Āyurveda, a traditional system of medicine, is also attributed to him. The name has also been applied to other semilegendary and historical physicians and to a legendary king.

Dhār, town, western Madhya Pradesh state, central India. The town, a major agricultural centre, is connected by road with Indore. Cotton ginning and handicraft weaving are the chief industries. On the northern slopes of the Vindhya Range, Dhār commands one of the gaps leading to the Narmada River valley.

An ancient town, it served (9th–14th century) as the capital of the Paramāra Rājputs and was a centre of learning under the celebrated Raja Bhōja (c. 1010–55). It was conquered by the Muslims in the 14th century, was under Mughal dominion, and fell to the Marāṭhās in 1730, after which it served as the capital of Dhār princely state, founded in 1742 by Anand Rāo Panwār, a Marāṭhā chieftain.

Dhār's Lāṭ Masjid, or Pillar Mosque (1405), was built out of the remains of Jaina temples. Its name was derived from an overthrown iron pillar (13th century) bearing a later inscription

recording the visit of the Mughal emperor Akbar in 1598. Dhār also houses the Kamal Maula mausoleum and a mosque known as Raja Bhōja's school, built in the 14th or 15th century; its name was derived from its paved slabs covered with inscriptions giving Sanskrit grammatical rules. Just north stands a 14th-century fort, said to have been built by Muḥammad ibn Tughluq, which contains the raja's palace. The town has a library, a hospital, a musical academy, and a government college affiliated with Vikram University.

The region around Dhār comprises portions of the Mālwa Plateau and the Nimār tract, separated by the Vindhya Range. Sorghum, corn (maize), pulses, and cotton are the chief crops, irrigated by the Mahi, Narmada, and Chambal river systems. Pop. (1991) 59,200.

Dharamsāla (India): *see* Dharamsāla.

dharana, Sanskrit DHĀRAṆĀ, in the Yoga system of Indian philosophy, the sixth of the eight stages intended to lead the aspirant to samādhi ("self-collectedness"), the state of perfect concentration. In dharana, the mind concentrates its attention on a single external object. Sufficient prolongation of dharana results in a deeper state of concentration, dhyana (Sanskrit: "concentrated meditation"), in which there is a constant identification between the meditator and the object of meditation. These two stages and the final one of samādhi are much alike and may be difficult to differentiate from one another.

dharani, Sanskrit DHĀRAṆĪ, in Buddhism and Hinduism, a sacred verse of great efficacy, used by the common man as a verbal protective device or talisman and by the yogi (spiritual adept) as a support or instrument for concentration. The dharani is a short summary of the essential doctrine contained in a much longer sacred text and serves as an aid to its retention. Properly recited, the dharani conveys the same merit as reading the entire work. The meaning of a dharani is often very difficult to determine and may sound to the uninitiated like a string of meaningless words, the accuracy of which is, nevertheless, carefully guarded when passed on from teacher to pupil. *Compare* mantra.

dharma, Sanskrit DHARMA, Pāli DHAMMA, key concept with multiple meanings in Hinduism, Buddhism, and Jainism.

In Hinduism dharma is the religious and moral law governing individual conduct and one of the four ends of life, to be followed according to one's class, status, and station in life. It constitutes the subject matter of the dharmasūtras, religious manuals that are the earliest source of Hindu law, and in the course of time has been extended into lengthy compilations of law, the dharmashastra (q.v.).

In Buddhism, dharma is the doctrine, the universal truth common to all individuals at all times, proclaimed by the Buddha. Dharma, the Buddha, and the sangha (community of believers) make up the triratna, or "three jewels," the primary statement of Buddhist belief. In Buddhist metaphysics the term in the plural (dharmas) is used to describe the interrelated elements that make up the empirical world.

In Jaina philosophy, dharma, in addition to being commonly understood as moral virtue, also has the meaning—unique to Jainism—of an eternal "substance" (*dravya*: q.v.), the medium that allows beings to move.

Dharma-Ṭhākur, also called DHARMA-RAY, folk deity of eastern India of complex characteristics and obscure origins. Dharma-Ṭhākur

is worshiped as the "high god" of a large number of villages of the Rahr Plains, a region that comprises the greater part of modern West Bengal state. Dharma-Ṭhākur has no prescribed form; he is worshiped in the form of stones, as a wooden votive slab, or through a pair of wooden sandals. Among other attributes he is a fertility god and a healer of disease. Worship of Dharma-Ṭhākur is correlated with sun worship, and Dharma-Ṭhākur's annual worship, known as Dharma-pūjā, has been described as a kind of sympathetic magic to make the monsoon rains begin to fall.

Scholars are not agreed on the origins of worship of Dharma-Ṭhākur. Some find in the deity and his worship a degenerate form of the Buddha and Buddhism; others trace the cult and deity to either pre-Aryan or tribal sources. Among the neighbouring literate tribal peoples there are a number of cult practices and deities that share some of the characteristics of Dharma-Ṭhākur and his cult. The majesty and exploits of Dharma-Ṭhākur are presented in a major class of works in Bengali literature known as *Dharma-maṅgal*.

Dharmakīrti (fl. 7th century), Indian Buddhist philosopher and logician. He asserted that inference and direct perception are the only valid kinds of knowledge and that, in the processes of the mind, cognition and the cognized belong to distinct moments. According to him, the object of inference, either analytical or synthetic, is the universal (*sāmānyalakṣaṇa*) and the object of perception—which may be perceived by the five senses, by the mind, by self-consciousness, or by the practice of Yoga—is the pure particular (*svlakṣaṇa*).

Dharmakīrti claimed that every person is a transitory being and, in his turn, assumes the continuous existence of an individual. The individual is a continuation of moments, compiled by imaginative and discriminative thinking.

dharmapāla (Sanskrit: "defender of the religious law"), Tibetan DRAG-GSHED ("cruel, wrathful hangman"), in Tibetan Buddhism, any one of a group of eight divinities who, though benevolent, are represented as hideous and ferocious in order to instill terror in evil spirits.

Worship of *dharmapālas* was initiated in the 8th century by the magician-saint Padmasambhava, who is said to have conquered the malevolent deities in Tibet and forced them to take an oath promising to protect Buddhists and the Buddhist faith. Many of the *dharmapālas* can be linked to Hindu, Bon (the indigenous religion of Tibet), or folk deities.

The *dharmapālas* are shown in painting, in sculpture, and in masks used by dancers as scowling figures with a third eye and disheveled hair, wearing crowns of skulls and garlands of severed heads; they are depicted treading on human beings or animals, usually in the company of their female consorts. They are worshiped singly or in a group called the "Eight Terrible Ones," which most commonly includes the following: (1) Lha-mo (Tibetan: "Goddess"; Sanskrit: Śrī-devī, or Kāla-devī), fierce city goddess of Lhasa and the only feminine divinity in the group; (2) Tshangs-pa Dkar-po (Tibetan: "White Brahmā"; Sanskrit: Sita-Brahmā); (3) Beg-tse (Tibetan: "Hidden Sheet of Mail"); (4) Yama (Sanskrit; Tibetan: Gshin-rje), the god of death, who may be accompanied by his sister, Yamī; (5) Kubera, or Vaiśravaṇa (Tibetan: Rnam-thos-sras), god of wealth and the only one among the eight who is never represented in a fierce form; (6) Mahākāla (Sanskrit: "Great Black One"; Tibetan: Mgon-po); (7) Hayagrīva (Sanskrit: "Horse Neck"; Tibetan: Rta-mgrin); and (8) Yamāntaka (Sanskrit: "Conqueror of Yama, or Death"; Tibetan: Gshin-rje-gshed).

The *dharmapālas* are worshiped in the *mgon khang*, a subterranean room, the entrance to

Lha-mo, one of the *dharmapālas*, 19th-century Tibetan painting; in the Rijksmuseum voor Volkenkunde, Leiden, Neth.

By courtesy of the Rijksmuseum voor Volkenkunde, Leiden, Neth

which is often guarded by stuffed wild yaks or leopards. Priests wear special vestments and use ritual instruments often made of human bone or skin. Worship includes the performance of masked dances (*'chan*).

Dharmapuri, town, northwestern Tamil Nādu state, southeastern India. It was known in early Tamil *caṅkam* literature as the home of the poet Avvaiyār (2nd century AD). It is now an agricultural trade centre and contains some light industry. About 30 miles (48 km) west are the Hogenakal Falls of the Cauvery River, a famous pilgrimage site. Considerable deposits of saltpetre and salts of soda are mined in the region in which Dharmapuri lies. The area's main crops are millets, but rice is extensively grown under irrigation. Cotton, sesame seed, and peanuts (groundnuts) are the chief cash crops. There are also high-quality cattle. Pop. (1991) town, 59,070.

dharmashastra, also spelled DHARMAŚĀTRA, Sanskrit DHARMA-ŚĀSTRĀ ("righteousness science"), ancient Indian body of jurisprudence that is still fundamentally the family law of Hindus living in territories outside India (e.g., Pakistan, Malaysia, East Africa) and is in force, subject to legislative modification, in India. Dharmashastra is not primarily concerned with legal administration, though courts and their procedures are dealt with comprehensively, but with the right course of conduct in every dilemma. Some basic principles of dharmashastra are known to most Hindus brought up in a traditional environment. These include the propositions that duties are more significant than rights, that women are under perpetual guardianship of their closest male relatives, and that the king (*i.e.*, the state) must protect the subjects from all harm, moral as well as material.

The dharmashastra literature, which is written in Sanskrit, exceeds 5,000 titles. It can be divided into three categories: (1) sutras (terse maxims); (2) smritis (shorter or longer treatises in stanzas); and (3) *nibandhas* (digests of smriti verses from various quarters) and *vytis* (commentaries upon individual continuous smritis). The *nibandhas* and *vytis* are juridical works intended for legal advisers and exhibit considerable skill in harmonizing divergent sutras and smritis.

The techniques of the dharmashastra are mainly to state the ancient text, maxim, or stanza and to explain its meaning, where

obscure, to reconcile divergent traditions, if necessary by use of the traditional science of interpretation (Mīmamsā). Where possible, dharmashastra permits custom to be enforced, if it can be ascertained and if its terms are not repugnant to the principles of life as understood by Brahmans (those of the priestly class). Brahman ethics have given dharmashastra its colour and provided a test under which many customs of the Hindu peoples could be administered by Hindu kings.

Ancient Hindu jurisprudence was introduced to the West by Sir William Jones, 18th-century British Orientalist and jurist. Many who followed him—e.g., Sir Henry Maine (1822–88)—believed dharmashastra was a kind of priestcraft, intended to keep the lowest castes, the Śūdras and the untouchables, under the control of the higher castes. The close study of dharmashastra sources by German and Italian scholars, principally G. Bühler, Julius Jolly, and Giuseppe Mazzarella, showed its psychological and sociological potential.

Dharmashastra is equal in age to Jewish law (or older, if its roots do indeed go back to the Vedas), but its sources are more accessible, more varied, and less codified. It differs from Roman law in these respects but especially in its greater continuity and longevity. The British colonial administration in India affected the system of Hindu law by applying the traditional rules in a hard-and-fast way and by introducing the concept of precedent. Rapid social change, following foreign rule, required many adjustments to India's body of Hindu law. There was, for example, no provision in the dharmashastra for the development of judicial divorce or the allotting of equal shares to daughters along with sons in their fathers' estate at his death. This would have necessitated inventing new texts, which was impossible. Hence, first piecemeal and later comprehensive legislation, in 1955–56, altered the system of Indian law administered in the courts. Gradually, as judges lost familiarity with Sanskrit, the ancient texts began to be replaced with contemporary, cosmopolitan juridical and social concepts.

dharmasutra, Sanskrit DHARMA-SŪTRĀ ("righteousness thread"), any of several manuals of human conduct that form the earliest source of Hindu law. They consist chiefly of

Dhaulāgiri mountain, seen from the Kāli Gandak River gorge, north-central Nepal

AP/Wide World Photos

strings (or "threads") of terse rules containing the essentials of law relating to man and his fellows and to man and the state. The maxims deal with the practical rules of caste and of human beings in their social, economic, and religious relations. Formulated in prose, they were intended to be committed to memory and expounded orally by teachers—thus forming, as it were, epitomes of class lectures. Eventually these rules came to be interspersed with stanzaic verses in various metres, each generally giving the substance of the rule im-

mediately preceding it. The verses themselves became increasingly popular and ultimately led to the appearance of works entirely in verse. These metrical versions of previously existing dharmasutras came to be called dharmashastras, though in modern times that term more commonly is used to denote the whole body of customary rules and observances governing Hindu religious and social life.

Dharmavamsa, also spelled DHARMAWANGSJA, or DHARMAWANGSA (d. c. 1007, Java [now in Indonesia]), king of eastern Java from about 985 and the first historical Javanese whose life is known in any detail.

Dharmavamsa was a Saivite king whose reign is noted for its literary achievements, including a translation of the Hindu epic *Mahābhārata* into Javanese. A legal code that the king developed is still in use in Bali. He established tributary relations with Bali and parts of Borneo and attacked the powerful Sumatran kingdom of Śrīvijaya, which retaliated with a military expedition that decimated eastern Java; Dharmavamsa himself was killed. His kingdom was later restored under the leadership of his son-in-law Erlangga.

Dharmshāla, also spelled DHARMAŚĀLA, city, western Himāchal Pradesh state, northwestern India, located on a lower slope of the Himalayas. Dharmshāla is a scenic health resort. Aerated water is bottled there, and slate is quarried nearby. The city was virtually destroyed by an earthquake in 1905, but it was then rebuilt. The Dalai Lama took up residence in Dharmshāla when he was forced into exile from Tibet in 1959. Pop. (1991) 17,320.

Dhārwād-Hubli (India): see Hubli-Dhārwād.

Dhaulāgiri, mountain massif of the Himalayas in north-central Nepal, on the western side of the deep Kāli Gandak River gorge. Many of its snow- and glacier-covered peaks exceed 25,000 feet (7,620 m), including Dhaulāgiri I, II, III, and IV. At 26,795 feet (8,167 m), Dhaulāgiri I is one of the world's highest mountains. With a south wall 15,000 feet (4,600 m) high, the peak's steep sides and bitter climate prevented an ascent to the top until May 13, 1960, when a Swiss expedition

led by Max Eiselin reached the summit. The name of the peak is derived from two Sanskrit words meaning "white mountain."

Dhaun, Leopold Joseph, Count (Graf) von: see Daun, Leopold Joseph, Count (Graf) von.

Dhebar Lake, large reservoir lake, in the southeastern Arāvalli Range, south-central Rājasthān state, northwestern India. The lake, approximately 20 square miles (50 square km) in area when full, was originally named Jai

Samand and was formed by a marble dam built across the Gomati River in the late 17th century. Canals carry water from the lake to villages in the western area. Small wooded islands dot the northern end of the lake, where fishing hamlets fringe the shore. Two palaces stand on the hills to the south.

Dhekélia, also spelled DEKÉLEIA, British military enclave in southeast Cyprus, retained as a "sovereignty base area" by the United Kingdom under the 1959 London Agreement granting independence to Cyprus. It is located northeast of Larnaca on the northern shore of Larnaca Bay, and its northern boundary formed part of the border between the Republic of Cyprus (south) and the Turkish Cypriot administered area (north) established in 1974. It has a hospital and a small airfield. The base, together with Akrotiri sovereign base to the southwest (together totaling 99 square miles [256 square km]), is used as a British training and staging area and for support of the United Nations forces on Cyprus.

Dhenkānāl, town, east-central Orissa state, eastern India. Named for Dhenka, a medieval chieftain of the Savara (Saora, or Sora) tribe. Dhenkānāl is a marketplace for rice, oilseeds, and timber and is a centre of handloom weaving. It was formerly the capital of the princely state of Dhenkānāl, which was incorporated in 1949 into Orissa state. The raja's palace is on a hill encircled by moats. The town is the site of Dhenkānāl College (established 1959).

Rice and oilseeds are grown in the surrounding area, and forest products are important. Textiles, brass utensils, and other cottage industries are widespread. Pop. (1991) 46,250.

Dhibān (Jordan): see Dibon.

dhikr, also spelled ZIKR (Arabic: "reminding oneself," or "mention"), ritual prayer or litany practiced by Muslim mystics (Sūfis) for the purpose of glorifying God and achieving spiritual perfection. Based on the Qur'anic injunctions "Remind thyself [*udhkur*] of thy Lord when thou forgettest" (18:24) and "O ye who believe! Remember [*udhkurū*] Allāh with much remembrance" (33:41), the dhikr is essentially a "remembering" of God by the frequent repetition of his names. Originally a simple recitation of the Qur'ān and various religious writings among ascetics and mystics, the dhikr gradually became a formula (e.g., *lā ilāha illa 'llāh*, "there is no god but God"; *Allāhu akbar*, "God is greatest"; *al-ḥamdu lillāh*, "praise be to God"; *astaghfiru 'llāh*, "I ask God's forgiveness"), repeated aloud or softly, accompanied by prescribed posture and breathing. As the Sūfi brotherhoods (*ṭarīqahs*) were established, each adopted a particular dhikr, to be recited in solitude (e.g., following each of the five obligatory daily prayers) or as a community. The dhikr, like *fikr* (meditation), is a method the Sūfi may use in his striving to achieve oneness with God.

Dhiliyiānnis, **Theódoros**, Dhiliyiānnis also spelled DELIGIANNIS, or DILYIYANNIS (b. April 1826, Kalávrita, Greece—d. May 13 or June 13, 1905, Athens), politician who was prime minister of Greece five times (1885–86, 1890–92, 1895–97, 1902–03, 1904–05). He was a resolute advocate of aggressive and often irresponsible irredentism. His bitter rivalry with the reformist politician Kharilaos Trikoúpis dominated Greek politics for the last quarter of the 19th century.

Dhiliyiānnis, who studied law at the University of Athens, first became prominent as Greece's foreign minister in 1862. He was ambassador in Paris (1867–68), and in 1877, as foreign minister in the government of Aléxandros Koumoundhoúros, he advocated Greek intervention in the Russo-Turkish War;

the following year he was a delegate to the Congress of Berlin, which sought to solve the Eastern Question.

While his rival Trikoúpis advocated constitutional government and internal reform, Dhiliyiānnis, a supporter of the Great Idea (Megáli Idéa) that promised the liberation of all Greeks under Turkish rule and even the recovery of Constantinople (Istanbul), occupied himself primarily with an aggressive foreign policy and organized his followers into the conservative Nationalist Party, in opposition to Trikoúpis' Liberal Party. In 1885 Dhiliyiānnis formed his first government and, inspired by the Bulgarian declaration of complete independence from Turkey, prepared to invade Turkish Macedonia, an adventure that was stopped only when the great powers blockaded Greek ports.

Dhiliyiānnis became prime minister again in 1890 and 1895. Spurred on by the 1896 revolt on Crete against Turkish rule, he declared war on Turkey in April 1897, sending a fleet to the island and an army led by Crown Prince Constantine into Macedonia and Epirus. The army was defeated, and Greece was forced to yield 12 strategic points along its northern border to Turkey. Resigning as prime minister, Dhiliyiānnis kept his seat in the Chamber of Deputies, though he had lost much of his popular following. Nevertheless, he was prime minister again in 1902–03 and from December 1904 until his assassination by opponents of his strict measures against gambling syndicates.

Dhílos (Greece): see Delos.

Dhlomo, **R(olfus) R(eginald) R(aymond)** (b. 1901, Siyamu, Natal [South Africa]—d. 1971), African novelist, journalist, and editor who wrote in Zulu and English. His *An African Tragedy* (1928) was the first novel in English by a Zulu writer.

Dhlomo attended the Ohlange Institute in his hometown and then earned a teacher's certificate from Adams College at nearby Amanzimtoti. He contributed sketches and moral tales to *The Sjobok*, *Ilanga lase Natal*, and *The Bantu World* before becoming editor of *The Bantu World* (1942–43) and *Ilanga lase Natal* (1943–60), for which he wrote a leading feature in English and numerous articles in Zulu.

An African Tragedy, a novel about the corrosive effects of the city on a pair of lovers from the country, is a Christian fable of sin and forgiveness. Dhlomo's major novels in Zulu—*UNomalanga kaNdengezi* (1934; "Nomalanga, Daughter of Ndengezi") and *Indlela yababi* (1946; "The Way of the Wicked")—paint portraits of Zulu life in Natal and Johannesburg, respectively. Many of his other Zulu works are semibiographical accounts about members of the Zulu dynasty.

Dhodhekánisos (Greece): see Dodecanese.

Dhofar, also spelled DHUFAR, Arabic ZUFAR, historical region in southern Oman, extending from Cape Ash-Sharbatāt on the coast of the Arabian Sea southwestward to the Oman-Yemen border. The region's northern boundary has never been defined, but generally included in the territory is the Wadi Mughshin, located about 150 miles (240 km) inland. To the northeast of Dhofar is a large desert of stony plains and sand dunes that contribute to the region's isolation from northern Oman. The Ṣalālāh coastal plain (about 40 miles [64 km] long and ranging from 1 to 6 miles [1.5 to 9.5 km] wide), facing the Arabian Sea, is considered one of the most beautiful in Arabia, particularly in its southwestern part, because of its monsoon climate and temperate vegetation and bird life; the region has constantly flowing streams, making it Oman's most fertile area. About 10 miles (16 km) inland the rugged al-Qarā' Mountains rise to heights of between 3,000 and 4,000 feet (900 and 1,200

m). Farther north the al-Qarā' Mountains give way to a pebbly desert, beyond which lies the Rub' al-Khalī ("Empty Quarter") of Saudi Arabia.

Dhofar is one of the locations suggested for the Ophir of the Bible; the earliest known settlement in the region dates back to the 12th century BC. By the close of the 12th century AD the region was ruled as a tributary of Oman by Aḥmad ibn-Mohammad al-Manjawa. In the early 19th century it was governed by Moḥammad ibn-Agil al-Ajaibi. In 1965, Ohotari tribesmen, supported by neighbouring Yemen (Aden), rebelled against Sultan Sa'īd ibn Taymūr's restrictive policies; they were defeated in 1975.

Major crops in Dhofar include coconuts, alfalfa, sorghum, bananas, and vegetables. The region is the world's leading source of frankincense. Dhofar is Oman's cattle-raising area, primarily for milk. There are oil fields in the northeast. The coastal town of Ṣalālāh, sprawled along a sandy beach, was the permanent residence of the former sultan of Oman. Other major towns, all situated on the plain, include Mirbāt, Tāqah, Raysūt, and Rakhūt. A road from Ṣalālāh crosses the al-Qarā' Mountains north to Thamril, where a graded road continues northward. The mountain sector is inhabited almost exclusively by the Qara, Sheva, and Mahra peoples; the majority of the peoples on the Ṣalālāh plain are Najd and Kathir.

Dhok (Iraq): see Dahūk.

dhole, also called RED DOG (species *Cuon alpinus*), wild Asian carnivore of the dog family (Canidae), found in central and southeastern

wooded areas and distinguished structurally by the lack of one pair of lower molars. Its length ranges between 76 and 100 cm (30 and 40 inches), exclusive of the 28–48-centimetre (11–19-inch) tail, and its weight is from 14 to 21 kg (30 to 46 pounds). Coloration varies from yellowish to reddish brown, often with lighter underparts. Dholes hunt various mammals, generally associating in packs of up to 30 individuals; they usually hunt such prey as deer and wild sheep but are reported to attack animals as large as tigers and bears. A litter usually contains two to six pups, born after a nine-week gestation period.

Dholpur, town, eastern Rājasthān state, northwestern India, situated just north of the Chambal River. The original town was founded by Raja Dholan Deo in the 11th century, when it was called Dhawalpur, a name since contracted to Dholpur. The present town was established just north of the original town to avoid encroachments by the Chambal River. It was the capital of the former princely state of Dholpur, which became part of the state of Rājasthān in 1949. Several temples surround nearby Machkund Lake, on the shores of which annual religious fairs are held. An agricultural distribution centre, Dholpur is connected by Grand Trunk Road with Agra and Delhi to the north and with Gwalior to the south. The town has railway workshops, and industries include handloom carpet weav-

ing and glass manufacturing. Dholpur has a hospital and one college. Cattle and horse fairs are held annually. Pop. (1991) 68,524.

dhōti, long loincloth traditionally worn in southern Asia by Hindu men. Wrapped around the hips and thighs with one end brought between the legs and tucked into the waistband, the dhōti resembles baggy, knee-length trousers.

style, required great breath control. It was used in praise of heroes, gods, and kings.

Dhū al-faqār, in Islāmic mythology, the two-pointed magical sword that has come to represent 'Alī, fourth caliph and son-in-law of Muḥammad. Originally owned by an unbeliever, al-'Aṣ ibn Munabbih, Dhū al-faqār came into Muḥammad's possession as booty from the Battle of Badr (624). He in turn

The lightweight cotton fabric, also called dhōti, that is used for the garment is usually white and is often bordered in brightly coloured stripes. It was originally called a *paridhana*. Sculptured reliefs dating from the 2nd century BC show the ancient dhōti as a garment worn by both sexes. Derivatives of the dhōti are the panung of Thailand, the comboy of Sri Lanka, and the sarong of Indonesia and Malaysia.

dhōum nut: see doum nut.

dhōw, also spelled DOW, one- or two-masted Arab sailing vessel, usually with lateen rigging (slanting, triangular sails), common in the Red Sea and the Indian Ocean. On the larger types, called baggalas and booms, the mainsail is considerably bigger than the mizzensail. Bows are sharp, with a forward and upward

passed it on to 'Alī, and the sword, said to have borne an inscription ending in the words *lā yuqatl Muslim bi-kāfir* ("no Muslim shall be slain for [the murder of] an unbeliever"), eventually rested with the 'Abbāsīd caliphs.

As 'Alī's legendary status grew, the importance of his association with Dhū al-faqār also increased. Particularly in legends surrounding the Battle of Šiffin (657), Dhū al-faqār, the two points of which were useful for blinding an enemy, is credited with enabling 'Alī to perform phenomenal military feats, decapitating or cutting in half more than 500 men.

In Muslim countries, fine swords have traditionally been engraved with the phrase *lā sayfa illā Dhū al-faqār* ("there is no sword but Dhū al-faqār"), often with the addition *wa lā fatā illā 'Alī* ("and there is no hero but 'Alī").

Dhū an-Nūnid DYNASTY, 11th-century Muslim Berber dynasty of Toledo that ruled central Spain from Guadalajara and Talavera to Murcia during the unruly period of the party kingdoms (*tā'ifas*). As early as the mid-8th century the Banū Zannūn—their name was later Arabicized—had settled northeast of Toledo, where they became an influential family. In the civil war that broke up the Spanish Umayyad state (1008–31), 'Abd ar-Raḥmān ibn Dhū an-Nūn, who had been invited by the Toledans to rule their city, and his son Ismā'il az-Zāfir were the first local rulers to refuse to recognize the central authority of the Umayyad caliph of Córdoba. Az-Zāfir established himself as an independent king in Toledo and, despite constant wars with the Christians, ruled until 1043. His son Yahyā al-Ma'mūn (reigned 1043–75) allied with Christians several times against his Muslim enemies and even entertained King Alfonso VI of Castile and Leon at his court (1072). In 1065 al-Ma'mūn seized the 'Amirid capital of Valencia and in 1074–75 was able to take Córdoba, the former seat of the Umayyads. But Yahyā al-Qādir (reigned 1075–92), al-Ma'mūn's grandson, soon lost both Valencia and Córdoba. An alliance with Alfonso VI hastened the end of the Dhū an-Nūnid kingdom: while al-Qādir was briefly restored to Toledo, he bargained away his capital to the Christians in return for Valencia (1085), where he was assassinated in 1092.

Dhūlia, also called DHULE, town, northwest of Mahārāshtra state, western India, on major road and rail routes. In early Muslim times it belonged to the Fārūquis, but later, in 1601, it became part of the Mughal Empire. Later conquered by Marāṭhās in the 18th century and ceded to the British in 1818, it joined Bombay Presidency in 1818. Formerly an agricultural commercial centre, Dhūlia has become a growing industrial town, with a cotton-textile mill and such small-scale industries as cotton ginning, cigarette making, and oil processing. It has 13 colleges affiliated with the University of Poona.

The large area around Dhūlia contains two main hill systems—the Sātpura (north) and Sātmāla (south) ranges—which are offshoots of the Western Ghāts. Between them the Tāpti River flows through a fertile valley that is part of the cotton-growing Khāndesh region. Other important crops are peanuts (groundnuts) and chilies; most of the agricultural produce is shipped to Bombay. The hills are forested and contain the resort town of Toranmal. Pop. (1991) town, 278,317.

Dhulip Singh: see Dalip Singh.

dhyāna, in Indian philosophy, a stage in the process of meditation leading to Nirvāṇa. See Buddhist meditation.

Dhyāni-Buddha, in Mahāyāna and Vajrayāna (Tantric) Buddhism, any of a group of five "self-born" Buddhas who have always existed from the beginning of time; the five are usually identified as Vairocana, Akṣobhya, Ratnasambhava, Amitābha, and Amoghasiddhi.

Scholars in recent years have pointed out that the term Dhyāni-Buddha does not appear in the original texts, but the nomenclature continues to be commonly used, particularly in describing groups of images composed of five meditating Buddhas—as in mandalas (ritual meditation designs), on the four sides and top of votive *stūpas* (commemorative monuments), or on the terraces of the great monument at Borobudur in Indonesia.

The five are almost identically represented in art, all dressed in monastic garments, seated with folded legs, with the same hairdress and long-lobed ears, but are distinguished by characteristic colours, symbols, poses of hands, and the directions they face. The five eternal Buddhas are correlated to other groups of five, so that the entire cosmos is seen as

Dhow under sail off the coast of Zanzibar

thrust, and the sterns of the larger dhows may be windowed and decorated.

dhrupad, in Hindustani music, ancient vocal musical form in four parts preceded by extensive introductory improvisation (*ālāpa*) and expanded by rhythmic and melodic elaborations. It is related to the shorter, later *kayāl*, which has somewhat eclipsed the *dhrupad* in popularity.

The classical *dhrupad*, heavy and majestic in

A Dhyāni-Buddha on one of the *stūpa* terraces at Borobudur, Java, 8th century

divided between them and as emanating from them. Thus, each represents one of the five *skandhas*, or mental and physical aggregates which make up the whole of cosmic as well as individual existence.

According to the full exposition of this scheme, most of the other deities in the vast Buddhist pantheon are related to one of the five Buddhas as members of his "family"; reflect his distinguishing characteristics, such as colour, direction, and symbol; and when represented in art often carry an image of the "parent" Buddha in their crown. Each of the "self-born" Buddhas is also said to have manifested himself as an earthly Buddha and as a bodhisattva (Buddha-to-be). Each has his own consort, mount, sacred syllable, natural element, particular sense organ, special sense perception, and symbolic location in the human body.

In order to counter any tendency toward polytheism suggested by the fivefold scheme, some sects elevated one of the five, usually Vairocana, to a position of an Ādi-Buddha (first, or primal, Buddha). Sometimes a sixth deity is worshipped as the Ādi-Buddha. The Lamaist sects of Tibet identify the Ādi-Buddha as Vajradhara; some sects of Nepal give this position to Vajrasattva.

Di Stefano, Alfredo (b. June 4, 1926, Buenos Aires, Arg.), football (soccer) player and manager, regarded as one of the greatest centre forwards in football history. His reputation is based largely on his performance for the Spanish club Real Madrid (1953-64). He was twice named European footballer of the year (1957, 1959).

Di Stefano made his first division debut for the Buenos Aires club River Plate in 1944. In 1949 he joined the Millonarios of Bogotá, Colom., where he enjoyed four successful seasons. In 1953 Di Stefano arrived at Real Madrid, where he partnered with several outstanding forwards, including Ferenc Puskás. During his time in Madrid, Di Stefano led the league in scoring for four straight seasons (1956-59) and helped the team to eight first division titles (1954-55, 1957-58, 1961-64), one Spanish Cup (1962), and five European Champions Cups (1956-60). He ended his playing career in 1966 after two seasons with RCD Espanyol (in Barcelona). He played on both the Argentine and Spanish national teams in his career. Afterward Di Stefano coached in both Spain and Argentina.

diabase, also called **DOLERITE**, fine- to medium-grained, dark-gray to black intrusive igneous rock. It is extremely hard and tough and is commonly quarried for crushed stone, under the name of trap. Although not popular, it makes an excellent monumental stone and is one of the dark-coloured rocks commercially known as black granite. Diabase is widespread and occurs in dikes (tabular bodies inserted in fissures), sills (tabular bodies inserted while molten between other rocks), and other relatively small, shallow bodies. Chemically and mineralogically, diabase closely resembles the volcanic rock basalt, but it is somewhat coarser and contains glass. With increase in grain size, diabase may pass into gabbro.

About one-third to two-thirds of the rock is calcium-rich plagioclase feldspar; the remainder is mostly pyroxene. In diabase, poorly formed pyroxene crystals wrap around or mold against long, rectangular plagioclase crystals to give it the characteristic texture known as diabasic or ophitic. The larger pyroxene grains may completely enclose plagioclase; but as the quantity of the latter increases, pyroxene appears more interstitial.

Certain flat tabular masses (thick sheets or sills) of diabase, such as that forming the Palisades along the Hudson River near New York City, show concentrations of heavy minerals

(as olivine or pyroxene) in their lower portions. These concentrations are commonly believed to have developed by the settling of early formed crystals in molten diabase.

Diabase may show varying degrees of alteration: plagioclase is converted to sassurite; pyroxene to hornblende, actinolite, or chlorite; and olivine to serpentine and magnetite. In British usage, such altered rock is called diabase. Some diabase masses have been subdivided by systematic fractures into rectangular blocks. Subsequent alteration and weathering along these fractures have disintegrated and rounded off block corners and edges (spheroidal weathering), leaving regularly spaced, spherelike masses of fresh diabase enveloped by shells of progressively more altered and disintegrated material.

Diabelli, Anton (b. Sept. 6, 1781, Mattsee, near Salzburg, Archbishopric of Salzburg, Austrian Habsburg domain [now in Austria]—d. April 7, 1858, Vienna, Austria), Austrian music publisher and composer best known for his waltz, or ländler, on which Ludwig van Beethoven wrote his 33 variations for piano (*Diabelli Variations*, Opus 120).

He intended to enter the priesthood and entered the monastery at Raichenhaslach, where his studies were supervised by composer Joseph Haydn's brother Michael. Diabelli left in 1803, when the Bavarian monasteries were secularized, and went to Vienna, where he became a piano and guitar teacher. In 1818, with Peter Cappi, he founded a publishing firm, which he took over entirely in 1824. He published works of Franz Schubert, Carl Czerny, and Beethoven. In 1851 he issued the first thematic catalog of Schubert's works. His compositions include operettas, church music, and numerous light pieces.

diabetes insipidus, pathological endocrine condition characterized by extreme thirst and excessive production of very dilute urine. The essential feature of the disorder appears to be a lack of antidiuretic hormone (vasopressin) or a blocking of its action. This hormone, produced by the hypothalamus, regulates the kidney's conservation of water and production of urine.

The causes may be numerous: failure of osmoreceptors; tumours; inflammation of the hypothalamus or posterior pituitary lobe (neurohypophysis) by such diseases as syphilis or meningitis; granulomas; trauma, such as skull fracture or concussion; lesions; or failure of the tubules to respond to antidiuretic hormone.

The form of the disorder that results from injury to the hypothalamic nucleus, which is the tract by which vasopressin is conveyed to the neurohypophysis for storage, is called supraoptic hypophyseal diabetes insipidus, or SHDI. Nephrogenic diabetes insipidus (NDI) results when the supplies of vasopressin are adequate but the kidney tubules are unresponsive—either genetically or because of potassium depletion, high levels of serum calcium, or other disorders. SHDI can be alleviated by injections of vasopressin-like compounds of animal or synthetic origin; such treatment, however, is ineffective for NDI.

diabetes mellitus, disorder of carbohydrate metabolism resulting from insufficient production of or reduced sensitivity to insulin. A polypeptide hormone, insulin is synthesized in the beta cells of the islets of Langerhans of the pancreas and is necessary for normal utilization of glucose by most cells in the body. In persons who have diabetes, the normal ability of body cells to use glucose is inhibited, thereby increasing blood sugar levels (hyperglycemia). As more glucose accumulates in the blood, excess levels of sugar are excreted in the urine (glycosuria). Corresponding symptoms of diabetes include increased urinary volume and frequency, thirst, itching, hunger, weight loss, and weakness.

There are two varieties of the disease. Type I is insulin-dependent diabetes mellitus, or IDDM, for which insulin injection is required; it was formerly referred to as juvenile onset diabetes. In this type, insulin is not secreted by the pancreas and hence must be taken by injection. Type II, non-insulin-dependent diabetes mellitus, or NIDDM—which used to be called adult onset diabetes—may be controlled by dietary restriction. It derives from sluggish pancreatic insulin secretion and tissue resistance to secreted insulin, which is complicated by subtle changes in the secretion of insulin by the beta cells. Despite their former classifications as juvenile or adult, either type can occur at any age; NIDDM, however, is the most common type, accounting for 90 percent of all diabetes.

Diabetes mellitus (from Greek *diabainein*, "to pass through" and from Latin *mellitus*, "sweetened with honey") has been known since antiquity. Recovery from diabetes without treatment almost never occurs, although diabetes contracted by a mother during pregnancy—known as gestational diabetes—often resolves itself after delivery. While the exact causes of diabetes remain obscure, certain facts are evident. Beta cell damage in IDDM is the result of a process called autoimmunity, in which a diabetic person's immune system creates antibodies that destroy their own beta cells. NIDDM, on the other hand, is linked to heredity and obesity.

Many people are unaware that they have diabetes; in the late 20th century, for example, it was estimated that six million Americans had undiagnosed diabetes. The disease is usually discovered when there are typical symptoms and a clearly high blood sugar level, as defined by a daytime level greater than 200 milligrams per decilitre or a fasting level greater than 140 milligrams per decilitre. Occasionally a more detailed oral glucose tolerance test is required for accurate diagnosis.

Before the isolation of insulin in the 1920s, most patients died within a short time after onset. Untreated diabetes leads to ketosis, the accumulation of ketones, products of fat breakdown, in the blood; this is followed by acidosis (accumulation of acid in the blood) with nausea and vomiting. As the toxic products of disordered carbohydrate and fat metabolism continue to build up, the patient goes into diabetic coma.

Treatment aimed at controlling diabetes is highly successful. All patients are put on restrictive diets designed to help them reach and maintain normal body weight and to limit their intake of carbohydrates and fats. Frequently they are encouraged to exercise regularly, which apparently enhances the movement of glucose into muscle cells and blunts the rise in blood glucose that follows carbohydrate ingestion. Diabetics who are unable to produce insulin in their bodies receive regular injections of the hormone, often customized according to their individual and variable requirements. In addition to conventional beef-pork insulin—which is the pancreatic extract of pigs, sheep, and oxen—human insulin, based on recombinant deoxyribonucleic acid (DNA) technology, became available for use in the 1980s.

Research into other areas of insulin delivery include pancreas transplantation and implantable mechanical insulin infusion systems. Medication, in the form of oral hypoglycemic (blood-sugar-lowering) agents, was once commonly used to treat NIDDM but has fallen out of favour because of controversial reports of associated cardiovascular problems; such drugs are still used sparingly, however.

The objective of all forms of treatment of diabetes is to keep the level of blood sugar within normal limits and thus reduce the complications, primarily cardiovascular, that account for most diabetes-related deaths. Other serious

complications include a condition known as diabetic retinopathy (retinal changes leading to blindness), kidney disease, and frequent infection.

Diablo, Île du (French Guiana): see Devil's Island.

Diablo Range, segment of the Pacific Coast Ranges extending southeastward for about 180 miles (290 km) from the solitary Mount Diablo (3,849 feet [1,173 m]) within Mount Diablo State Park, about 20 miles (32 km) east of Oakland, Calif., to northwest Kern county in west-central California, U.S. It parallels the Pacific Ocean and forms part of the western wall of the Central Valley. Averaging 3,000 to 4,000 feet (914 to 1,219 m), the range is highest at San Benito Mountain (5,239 feet [1,597 m]). The name Monte del Diablo (Devil's Woods) referred to an Indian *rancheria* near the ridge and was first recorded in 1824. Cattle grazing, petroleum, and agriculture are the region's main economic activities.

diacetylmorphine (drug): see heroin.

diachronic linguistics: see historical linguistics.

diaconate, the office of a deacon (*q.v.*), or a body or board of deacons.

Diaconus, Paulus (Lombard historian and poet): see Paul the Deacon.

Diadectes, extinct genus of amphibians found as fossils in Lower Permian rocks in North America, dating from the Early Permian Period (286 to 258 million years ago). *Diadectes*

he was abducted by marauding Vandals and taken to Carthage, where he probably died.

A student of Evagrius Ponticus, the chief 5th-century proponent of Christian mysticism, Diadochus authoritatively reflected the major movements of Greek and Egyptian asceticism in his principal work, *Hekaton Kephalaia Gnōstika* ("The Hundred Chapters, or Maxims, of Knowledge"). Major themes in the work include man's creation in the image of God, the restoration of fallen man by grace, free will, mastery of human passions, and mystical contemplation through love. "The Hundred Chapters" also constitutes a polemic against Messalianism, the pietistic movement (condemned at the Council of Ephesus in 431) that claimed that in consequence of primeval sin everyone has a demon within his soul that can be exorcised only by ceaseless prayers. Rejecting extreme penitential practices, he submitted a tempered ascetical program as a means of achieving generosity of spirit.

"The Hundred Chapters" influenced Greek ascetical tradition; 16th-century Spanish mysticism; and the *Philokalia*, or 18th-century Russian prayer anthologies. Diadochus' orthodoxy and vindication of mystical experience appeared also in his "Homily on the Ascension." He responded to the problem of pantheistic interpretation of Christian mysticism in his *Horasis* ("The Vision") and *Catechesis* ("Instruction"). The Greek text of the *Catechesis*, probably an 11th-century redaction of Diadochus' thought, was discovered and edited in 1952 by Édouard Des Places, who also produced a new critical edition of

ation of a feldspar to form a distinctly new mineral in its place, a clay mineral.

Diaghilev, Sergey Pavlovich (b. March 31 [March 19, Old Style], 1872, Novgorod province, Russia—d. Aug. 19, 1929, Venice, Italy), Russian promoter of the arts who revitalized ballet by integrating the ideals of other art forms—music, painting, and drama—with those of the dance. From 1906 he lived in Paris, where, in 1909, he founded the Ballets Russes. Thereafter he toured Europe and the Americas with his ballet company, and he produced three ballet masterpieces by Igor Stravinsky: *The Firebird* (1910), *Petrushka* (1911), and *The Rite of Spring* (1913).

Diaghilev was the son of a major general and a noblewoman, who died in childbirth. As a youth his artistic sensibilities were encouraged by his stepmother, Helen Valerianovna

Diaghilev, c. 1916

had both reptilelike characteristics and primitive amphibian-like traits and is classified in the somewhat ambiguous order Seymouriamorpha. *Diadectes* grew to be about 6 feet (2 m) long. The skeleton was heavily constructed, with massive limbs, limb girdles, backbone, and ribs. The skull was relatively high and short. The teeth were blunt and peglike; *Diadectes* was probably one of the earliest terrestrial herbivores. The front teeth were longer than the cheek teeth and probably served to nip off plant material. The cheek teeth probably served to grind the plant material. See also Seymouria.

Diadochus OF PHOTICE (fl. 5th century), theologian, mystic, and bishop of Photice, Epirus, who was a staunch defender of orthodox Christological doctrine. His treatises on the ascetic life have influenced Eastern Orthodox and Western spirituality.

Little is known of Diadochus' life. At the Council of Chalcedon (451) and in a letter to the Eastern Roman emperor Leo I in 457, he refuted the heterodox monophysite tenet of a single, divine nature in Christ by maintaining Christ's dual (human and divine) natures. A late-5th-century chronicle, *Historia persecutionis Vandalorum* (1535; *The Memorable and Tragical History of the Persecution in Africke*) by Victor, bishop of Vita, commends Diadochus' catholic doctrine and indicates that

"The Hundred Chapters" (*Oeuvres spirituelles*, 1955).

diaeresis, also spelled DIERESIS (from Greek *dierein*, "to divide"), the resolution of one syllable into two, especially by separating the vowel elements of a diphthong and, by extension, two adjacent vowels, as in the word *cooperation*; it is also the mark placed over a vowel to indicate that it is pronounced as a separate syllable. In classical prosody, diaeresis refers to the end of a word coinciding with the completion of the metrical foot, in contrast to caesura, which refers to a word ending within a metrical foot.

diagenesis, sum of all processes, chiefly chemical, by which changes in a sediment are brought about after its deposition but before its final lithification (conversion to rock). Because most sediments contain mineral mixtures in which not all the minerals are in chemical equilibrium with each other, changes in interstitial water composition or changes in temperature or both will usually lead to chemical alteration of one or more of the minerals present. Diagenesis is considered a relatively low-pressure, low-temperature alteration process, whereas metamorphism is considered to be a rock-alteration process occurring at relatively higher pressures and temperatures. An example of diagenesis is the chemical alter-

Panayeva. He took piano lessons while at school and also showed a gift for composition.

In 1890, while studying law at the University of St. Petersburg, Diaghilev became associated with a group of friends interested in the social sciences, music, and painting—the first of a series of intellectual gatherings over which he presided throughout his life. Among his companions during this period were the painters Alexander Benois and Léon Bakst, both of whom were later to contribute brilliantly to his productions. In 1893 he made his first journey abroad, visiting Germany, France, and Italy, where he met the distinguished French novelist Émile Zola and the opera composers Charles Gounod and Giuseppe Verdi.

In 1896 Diaghilev graduated in law, but he was determined to follow a musical career. The composer Nikolay Rimsky-Korsakov, however, discouraged him from developing his talents as a composer, wisely no doubt, since a vocal work of Diaghilev that had been performed in public had left a poor impression. In Moscow he met the patron of the famed bass Fyodor Chaliapin and proposed revolutionary scenic ideas for productions of operas in which Chaliapin appeared. Although he was uncertain of his own artistic gifts, Diaghilev was convinced of his vocation: that of a patron of the arts like the Roman Gaius Maecenas. His theatrical ventures in the sphere of opera and ballet and his literary projects, demanding huge investments, were hampered by the

fact that he embarked on this career with no private income. Moreover, in 19th-century Russia, his homosexuality was a serious handicap in the development of his career. He had personal charm and audacity, however, and he used them to advantage.

In 1899 he realized the first of these international ventures when he founded, as editor in chief, the review *Mir Iskusstva* ("World of Art"), which continued to appear until 1904. This was a counterpart of the London *Yellow Book*, reflecting the ideas of the graphic artist Aubrey Beardsley and the writer Oscar Wilde. In 1905 Diaghilev organized a historic portrait exhibition of Russian art treasures at the Tauride Palace in St. Petersburg.

The great turning point in his life came when he left Russia for Paris in 1906. It was there that he helped to found what was later referred to as the Franco-Russian artistic alliance. He organized an exhibition of Russian art and then, in 1907, a series of historic concerts devoted to the work of the Russian nationalist composers. In 1908 Modest Musorgsky's opera *Boris Godunov* was produced in Russian by Diaghilev at the Paris Opéra with Fyodor Chaliapin in the title role.

The time had arrived for him to launch the venture that was to fulfill his ideal of a combination of the arts. Appointed in 1899 as assistant to Prince Sergey Volkonsky, director of the Imperial Theatre, Diaghilev had met the dancer Michel Fokine, who was powerfully influenced by the American dancer Isadora Duncan. Diaghilev, also influenced by the dance innovations of Duncan, as well as by the ideas of composer Richard Wagner and the theories of the poet Charles Baudelaire, opened his season of Ballets Russes at the Théâtre du Châtelet in Paris in 1909. The dancers Anna Pavlova, Vaslav Nijinsky, and Michel Fokine were in his company.

Before long it became clear that conventional choreography was to have no place in Diaghilev's novel spectacles. Mime or action dances were the aim of the choreographers who, largely under the influence of Fokine and Léonide Massine, were creating an entirely new tradition. The composers chosen to transform the old art forms were themselves inspired by the fantasies of painters and choreographers. This was Diaghilev's lofty creation: an ideal of artistic synthesis, based on an innate sense of taste. Diaghilev's art reached its height in the three early ballets of the young Russian composer Igor Stravinsky: *The Firebird* (1910), *Petrushka* (1911), and *The Rite of Spring* (1913). In *Petrushka*, perhaps the greatest of the Diaghilev ballets, Stravinsky, at Diaghilev's insistence, transformed a conventionally conceived piano concerto (on which he had been working) into a mimed ballet, bringing into real life the fantasy dramas of puppets at a showman's fair. The incident is indicative of the extraordinary psychological influence Diaghilev was able to exert over his collaborators. In *The Rite of Spring* Stravinsky produced one of the most explosive orchestral scores of the 20th century, and the production created an uproar in the Paris theatre at its first performance. The scandalous dissonances and rhythmic brutality of the music provoked among the fashionable audience such protestations that the dancers were unable to hear the orchestra in the nearby pit. They carried on, nevertheless, encouraged by the choreographer Nijinsky, who stood on a chair in the wings shouting out and miming the rhythm.

Diaghilev left his native Russia and never returned. In Paris he collaborated with the French poet Jean Cocteau, among others. He toured with his ballet throughout Europe, in the United States, and in South America. Seasons of the Diaghilev ballet were given uninterruptedly from 1909 to 1929. During

his later seasons he introduced the works of forward-looking composers and painters from France, Italy, Great Britain, and the United States. Among the composers represented in his repertory were Richard Strauss, Claude Debussy, Maurice Ravel, and Sergey Prokofiev.

Despite his influence, however, Diaghilev was a lonely and dissatisfied man, impecunious and personally unhappy. He was an idealist, never realizing perfection and yet sowing the seed of an exploratory spirit. Diaghilev had long suffered from diabetes, and by the end of his brilliant 1929 season at Covent Garden, London, his health had gravely deteriorated. He nevertheless left for a holiday in Venice, where he sank into a coma from which he did not recover. He was buried in the island cemetery of San Michele. (E.L.)

diagnosis, the process of determining the nature of a disease or disorder and distinguishing it from other possible conditions. This is accomplished by considering the patient's history and symptoms and by examining the patient in various other ways. The term diagnosis also refers to the identification reached by the physician or other examiner.

A brief treatment of diagnosis follows. For full treatment, see MACROPAEDIA: Diagnosis and Therapeutics.

The tools of the diagnostician include (1) a medical history, (2) a physical examination, and (3) tests and diagnostic procedures such as a complete blood count, an electroencephalogram (EEG), or a surgical biopsy.

A medical history is constructed from a medical interview conducted between physician and patient. It includes information about the present illness, past medical conditions of the patient and of the patient's family, occupational background, and psychosocial history, as well as a review of the major body systems. The family history is especially important for alerting the physician to any diseases family members may have or have had that would indicate the patient's increased risk for those conditions. The occupational history may provide information about exposure to substances in the workplace that might heighten the risk of contracting certain diseases. Emotional factors, such as stress, that could cause or exacerbate the condition may be revealed in the psychosocial background. The review of body systems, in which the physician discusses each major system of the body with the patient, can uncover symptoms or problems overlooked or unnoticed by the patient.

Following the medical interview, a physical examination of the patient is performed. This includes a visual inspection of the patient, palpation of organs, percussion of an area of the body (that is, tapping the surface of the body and evaluating the resulting sound) to determine the density of an organ or the presence of fluids, and auscultation (listening) with a stethoscope to evaluate sounds produced by the heart, lungs, bowels, or blood vessels.

The next step, called clinical decision making, is to assess the information collected from the medical history and physical examination and develop a list of possible causes. This list, known as the differential diagnosis, is culled by ordering tests and procedures that will provide further salient data about the disorder. The most likely candidate disease of the differential diagnosis is addressed first; if one of the less likely diseases is life-threatening, however, it will take precedence. Caution must be exercised to order only the most necessary

diagnostic tests and procedures so that the patient is not subjected to unnecessary risk, discomfort, or cost. While clinical testing may provide information that cannot be obtained from the medical history or physical examination, it may also yield false-positive or false-negative results that can complicate rather than aid the diagnostic process.

Some diseases are easily diagnosed; others are marked by vague symptoms that do not progress, and their diagnoses remain elusive. The ability of the physician to diagnose complex conditions requires not only keen observational skills but also a proficiency in reasoning. The experienced diagnostician also will rely on intuition developed from years of treating patients. Computers, which are used with increasing frequency as diagnostic tools, can be valuable, but they are not able to replace the experience and intuition of a skilled diagnostician.

diagnostic imaging, also called MEDICAL IMAGING, the use of electromagnetic radiation to produce images of internal structures of the human body for the purpose of accurate diagnosis. Diagnostic imaging is roughly equivalent to radiology (*q.v.*), the branch of medicine that uses radiation to diagnose and treat diseases.

X rays, used since 1895, were the first type of radiation to provide images of the interior of the body. X rays pass through bodily tissues and also have the property of darkening photographic film when they strike it. As they penetrate tissues, the X rays are absorbed differentially, with denser objects such as bones absorbing more of the rays and thus preventing them from reaching the film. Soft tissues, on the other hand, absorb fewer rays; the result is that in an X-ray photograph of the interior of the body, bones show up as lighter areas and soft tissues show up as darker ones on the exposed film.

A limiting factor in X rays when used alone is the inability to distinguish between adjacent, differentiated soft tissues of roughly the same density (*i.e.*, it is not possible to produce contrasting tones between such objects on the exposed film). To obtain this contrast, a contrast medium (*q.v.*)—a liquid or gaseous substance that is comparatively opaque to X rays (radiopaque) or comparatively transparent to them—is injected into the body. Contrast-medium fluids can be injected into naturally occurring body cavities, injected into the bloodstream and lymphatic vessels, swallowed or introduced by enema for study of the digestive tract, or injected around organs to show their external contour. Different contrast media thus allow the X-ray imaging of particular types of soft internal structures, such as the arteries and veins in angiography (*q.v.*), the passage of blood through the heart in angiocardiology (*q.v.*), the gallbladder and biliary channels in cholecystography (*q.v.*), the spinal cord in myelography (*q.v.*), and the urinary tract in urography (*q.v.*). Virtually any part of the body can be examined for physiological disturbances of the normal structures by X-ray analysis. X-ray motion-picture films can record the body processes as the contrast media enter and leave parts of the body.

Other imaging techniques have been developed using X rays. In tomography (*q.v.*), X-ray images of deep internal structures can be obtained by focusing the rays on a specific plane within the body. A more complex variation of this technique is computerized axial tomography, known as a CAT scan.

The scanning of radioactive isotopes that have been injected into the tissues is a medical specialty called nuclear medicine (*q.v.*). Both isotope scanning and X-ray photography are used in brain scanning (*q.v.*). An imaging technique related to isotope scanning is positron emission tomography (*q.v.*). Another type of diagnostic imaging is nuclear magnetic

resonance (*q.v.*), which creates images of thin slices of the body using very-high-frequency radio waves. Ultrasound is a technique in which high-frequency sound waves are used for detecting abnormalities in internal organs. The varieties of radiation that are used in diagnostic imaging continues to expand, along with the techniques for using them.

Diaguita, Indian peoples of South America, formerly inhabiting northwestern Argentina and the Chilean provinces of Atacama and Coquimbo. The Calchaquí, a northwestern Argentine subgroup of the Diaguita, are the best-documented. Their language affiliation remains uncertain.

The Calchaquí were described as warlike, and their stone fortifications located at strategic places in their territory attest to this. They became effective cavalrymen who carried the attack to Spanish towns. They farmed terraced fields, sometimes built irrigation canals, and also kept herds of llama. Their technological skill extended to the loom weaving of llama-wool textiles, which they dyed; basket making; and a rather elaborate ceramic industry. Metallurgy was also known. Religious beliefs involved shamanistic practices for the cure of illness felt to be caused by witchcraft.

dialect, a variety of a language that is used by one group of persons and has features of vocabulary, grammar, or pronunciation distinguishing it from other varieties of the same language that are used by other groups. The two main types of dialects are the geographic dialect, spoken by people of the same area or locality, and the social dialect, used by people of the same social class, educational level, or occupational group.

A brief treatment of dialect follows. For full treatment, see *MACROPAEDIA: Language*.

The development of dialect variations clearly shows that language is continually evolving. Sometimes, when varieties of a language change to the point that they are mutually incomprehensible, the dialects become languages in their own right. This was the case with Latin, various dialects of which evolved into French, Spanish, Italian, Portuguese, Romanian, and their various dialects. In some cases, the label "language" or "dialect" is attached because of political or nationalistic considerations, not linguistic ones such as mutual comprehensibility. In China, for example, although there is a common written language, some spoken dialects are so distinct that, technically, they should be called languages. Yet, assigning one language to a country that has diverse populations is politically expedient in that it has a unifying effect. Thus, the distinction between a dialect and a language is often blurred. Generally, dialects develop as a result of barriers that exist between various groups of people who speak the same language. These barriers can be geographic, economic, political, or social.

Regional dialectology was of interest to the historical linguists of the 19th century and the structural linguists of the first half of the 20th century. Recent research, however, has focused on linguistic variation that is due to social-class differences. The term dialect sometimes has a negative connotation in everyday use. More often than not, in the minds of nonlinguists, it connotes a deviation from the "standard" language, which is commonly thought to be superior. This standard language is, from the linguist's point of view, just another dialect, but it has more prestige than the others because it is spoken by the highly educated, a social elite, or simply a majority.

dialectic, also called **DIALECTICS**, originally a form of logical argumentation but now a philosophical concept of evolution applied to diverse fields including thought, nature, and history.

Among the classical Greek thinkers, the

meanings of dialectic ranged from a technique of refutation in debate, through a method for systematic evaluation of definitions, to the investigation and classification of the relationships between specific and general concepts. From the time of the Stoic philosophers until the end of the European Middle Ages, dialectic was more or less closely identified with the discipline of formal logic. More recently, Immanuel Kant denoted by "transcendental dialectic" the endeavour of exposing the illusion involved in attempting to use the categories and principles of the understanding beyond the bounds of phenomena and possible experience. G.W.F. Hegel identified dialectic as the tendency of a notion to pass over into its own negation as the result of conflict between its inherent contradictory aspects. Karl Marx and Friedrich Engels adopted Hegel's definition and applied it to social and economic processes. See also *dialectical materialism*.

dialectical materialism, a philosophical approach to reality derived from the teachings of Karl Marx and Friedrich Engels. For Marx and Engels, materialism meant that the material world, perceptible to the senses, has objective reality independent of mind or spirit. They did not deny the reality of mental or spiritual processes but affirmed that ideas could arise, therefore, only as products and reflections of material conditions. Marx and Engels understood materialism as the opposite of idealism, by which they meant any theory that treats matter as dependent on mind or spirit, or mind or spirit as capable of existing independently of matter. For them, the materialist and idealist views were irreconcilably opposed throughout the historical development of philosophy. They adopted a thoroughgoing materialist approach, holding that any attempt to combine or reconcile materialism with idealism must result in confusion and inconsistency.

Marx's and Engels' conception of dialectics owes much to G.W.F. Hegel. In opposition to the "metaphysical" mode of thought, which viewed things in abstraction, each by itself and as though endowed with fixed properties, Hegelian dialectics considers things in their movements and changes, interrelations and interactions. Everything is in continual process of becoming and ceasing to be, in which nothing is permanent but everything changes and is eventually superseded. All things contain contradictory sides or aspects, whose tension or conflict is the driving force of change and eventually transforms or dissolves them. But whereas Hegel saw change and development as the expression of the world spirit, or *Idea*, realizing itself in nature and in human society, for Marx and Engels change was inherent in the nature of the material world. They therefore held that one could not, as Hegel tried, deduce the actual course of events from any "principles of dialectics"; the principles must be inferred from the events.

The theory of knowledge of Marx and Engels started from the materialist premise that all knowledge is derived from the senses. But against the mechanist view that derives knowledge exclusively from given sense impressions, they stressed the dialectical development of human knowledge, socially acquired in the course of practical activity. Individuals can gain knowledge of things only through their practical interaction with those things, framing their ideas corresponding to their practice; and social practice alone provides the test of the correspondence of idea with reality—*i.e.*, of truth. This theory of knowledge is opposed equally to the subjective idealism according to which individuals can know only sensible appearances while things-in-themselves are elusive, and to the objective idealism according to which individuals can know supersensible reality by pure intuition or thought, independent of sense.

The concept of dialectical materialism—which is a theoretical basis for a method of reasoning—should not be confused with "historical materialism," which is the Marxist interpretation of history in terms of the class struggle.

There exists no systematic exposition of dialectical materialism by Marx and Engels, who stated their philosophical views mainly in the course of polemics.

dialectology, the study of dialects. Variation most commonly occurs as a result of relative geographic or social isolation and may affect vocabulary or features of grammar or pronunciation or both. Dialectology as a discipline began in the 19th century with the development in western Europe of dictionaries and grammars of regional dialects. Much of the work of dialectology has consisted of gathering information about the types of variation that occur in different dialects and the construction of linguistic atlases showing patterns of distribution for a series of varying features within a language. Such work on the geographic patterns of linguistic variation is also known as linguistic geography.

diallage, either of the two pyroxenes augite and diopside, which have well-developed, close-spaced, parallel partings commonly filled with magnetite or ilmenite. These filled partings are generally more pronounced than cleavage planes. Diallage is commonly dark green or bronze-coloured and often occurs as large crystals enclosing the silicate olivine in basic to ultrabasic rocks such as gabbro and peridotite. The term diallage is sometimes used in reference to a variety of diopside that has been altered by appreciable replacement by aluminum and other trivalent metal ions.

dialogue, in its widest sense, the recorded conversation of two or more persons, especially as an element of drama or fiction. As a literary form, it is a carefully organized exposition, by means of invented conversation, of contrasting philosophical or intellectual attitudes. The oldest known dialogues are the Sicilian mimes, written in rhythmic prose by Sophron of Syracuse in the early 5th century BC. Although none of these has survived, Plato knew and admired them. But the form of philosophic dialogue that he perfected by 400 BC was sufficiently original to be an independent literary creation. With due attention to characterization and the dramatic situation from which the discussion arises, it develops dialectically the main tenets of Platonic philosophy. To Lucian in the 2nd century AD the dialogue owes a new tone and function. His influential *Dialogues of the Dead*, with their coolly satirical tone, inspired innumerable imitations in England and France during the 17th and 18th centuries, *e.g.*, dialogues by the French writers Bernard de Fontenelle (1683) and François Fénelon (1700–12).

The revival of interest in Plato during the Renaissance encouraged numerous imitations and adaptations of the Platonic dialogue. In Spain, Juan de Valdés used it to discuss problems of patriotism and humanism (written 1533), and Vincenzo Carducci, theories of painting (1633). In Italy, dialogues on the Platonic model were written by Torquato Tasso (1580), Giordano Bruno (1584), and Galileo (1632). The Renaissance also adapted the dialogue form to uses unsuspected by either Plato or Lucian, such as the teaching of languages.

In the 16th and 17th centuries, dialogue lent itself easily and frequently to the presentation of controversial religious, political, and economic ideas. George Berkeley's *Three Dialogues Between Hylas and Philonous* (1713) are perhaps the best of the English imitations of Plato. The best-known 19th-century exam-

ples of the form are Walter Savage Landor's *Imaginary Conversations* (1824–29), sensitive re-creations of such historical personages as Dante and Beatrice. André Gide's *Interviews imaginaires* (1943), which explore the psychology of the supposed participants, and George Santayana's *Dialogues in Limbo* (1925) illustrate the survival of this ancient form in the 20th century.

Dialogue of the Ancients (Gaelic tale): see Interrogation of the Old Men, The.

dialysis, in chemistry, separation of suspended colloidal particles from dissolved ions or molecules of small dimensions (crystalloids) by means of their unequal rates of diffusion through the pores of semipermeable membranes. This process was first employed in 1861 by a British chemist, Thomas Graham. If such a mixture is placed in a sack made of parchment, collodion, or cellophane and suspended in water, the ions and small molecules pass through the membrane, leaving the colloidal particles in the sack. Separation by dialysis is a slow process, depending for its speed on the differences in particle size and diffusion rates between the colloidal and the crystalloidal constituents, and may be accelerated by heating or, if the crystalloids are charged, by applying an electric field (electrodialysis). For medical applications, see also artificial organ.

dialysis, also called HEMODIALYSIS, RENAL DIALYSIS, or KIDNEY DIALYSIS, in medicine, the process of removing blood from a patient whose kidney functioning is faulty, purifying that blood by dialysis, and returning it to the patient's bloodstream. The artificial kidney, or hemodialyzer, is a machine that provides a means for removing certain undesirable substances from the blood or of adding needed components to it. By these processes the apparatus can control the acid-base balance of the blood and its content of water and dissolved materials. Another known function of the natural kidney—secretion of hormones that influence the blood pressure—cannot be duplicated. Modern dialyzers rely on two physicochemical principles, dialysis and ultrafiltration.

In dialysis two liquids separated by a porous membrane exchange those components that exist as particles small enough to diffuse through the pores. When the blood is brought into contact with one side of such a membrane, dissolved substances (including urea and inorganic salts) pass through into a sterile solution placed on the other side of the membrane. The red and white cells, platelets, and proteins cannot penetrate the membrane because the particles are too large. To prevent or limit the loss of diffusible substances required by the body, such as sugars, amino acids, and necessary amounts of salts, those compounds are added to the sterile solution; thus their diffusion from the blood is offset by equal movement in the opposite direction. The lack of diffusible materials in the blood can be corrected by incorporating them in the solution, from which they enter the circulation.

Although water passes easily through the membrane, it is not removed by dialysis because its concentration in the blood is lower than in the solution; indeed, water tends to pass from the solution into the blood. The dilution of the blood that would result from this process is prevented by ultrafiltration, by which some of the water, along with some dissolved materials, is forced through the membrane by maintaining the blood at a higher pressure than the solution.

The membranes first used in dialysis were obtained from animals or prepared from collodion; cellophane has been found to be more

suitable, and tubes or sheets of it are used in many dialyzers. In the late 1960s hollow filaments of cellulose or synthetic materials were introduced for dialysis; bundles of such filaments provide a large membrane surface in a small volume, a combination advantageous in devising compact dialyzers.

Dialysis—which was first used to treat human patients in 1945—replaces or supplements the action of the kidneys in a person suffering from acute or chronic renal failure or from poisoning by diffusible substances, such as aspirin, bromides, or barbiturates. Blood is diverted from an artery, usually one in the wrist, into the dialyzer, where it flows—either by its own impetus or with the aid of a mechanical pump—along one surface of the membrane. Finally the blood passes through a trap that removes clots and bubbles and returns to a vein in the patient's forearm. In persons with chronic kidney failure, who require frequent dialysis, repeated surgical access to the blood vessels used in the treatments is obviated by provision of an external plastic shunt between them.

diamagnetism, kind of magnetism characteristic of materials that line up at right angles to a nonuniform magnetic field and that partly expel from their interior the magnetic field in which they are placed. First observed by S.J. Brugmans (1778) in bismuth and antimony, diamagnetism was named and studied by Michael Faraday (beginning in 1845). He and subsequent experimenters found that some elements and most compounds exhibit this “negative” magnetism. Indeed, all substances are diamagnetic: the strong external magnetic field speeds up or slows down the electrons orbiting in atoms in such a way as to oppose the action of the external field in accordance with Lenz's law.

The diamagnetism of some materials, however, is masked either by a weak magnetic attraction (paramagnetism) or a very strong attraction (ferromagnetism). Diamagnetism is observable in substances with symmetric electronic structure (as ionic crystals and rare gases) and no permanent magnetic moment. Diamagnetism is not affected by changes in temperature. For diamagnetic materials the value of the susceptibility (a measure of the relative amount of induced magnetism) is always negative and typically near negative one-millionth.

Diamantina, city, central Minas Gerais *estado* (“state”), southeastern Brazil. It lies in the mineral-laden Espinhaço Mountains at 4,140 feet (1,262 m) above sea level. Formerly called Tejuco, the city has some colonial buildings and a diamond museum. Textile mills, diamond-cutting and goldsmithing establishments, and ironworks contribute to the economy. Pop. (1996 prelim.) 36,200.

Diamantina River, intermittent river, east-central Australia, in the pastoral Channel Country (*q.v.*). It rises in Kirbys Nob, east of Selwyn, Queen., and flows (seasonally) for 500 miles (800 km) southwest past Birdsville to Goyder Lagoon in South Australia, draining a basin of 61,000 square miles (158,000 square km). In times of flood, the Diamantina River and the Georgina River (from the north) merge to drain along the channel of Warburton Creek southwestward to Lake Eyre. The Diamantina's principal tributaries are the Western and Mayne rivers. The Diamantina's average annual discharge at Birdsville is 890 cubic feet (25 cubic m) per second, ranging from 50,000 cubic feet (1,400 cubic m) per second in flood to nothing in dry years.

Diamir (Jammu and Kashmir): see Nānga Parbat.

diamond, a mineral composed of pure carbon. It is the hardest naturally occurring substance known; it is also the most popular gemstone.

Because of their extreme hardness, diamonds have a number of important industrial applications.

The hardness, brilliance, and sparkle of diamonds make them unsurpassed as gems. In the symbolism of gemstones, the diamond represents steadfast love and is the birthstone for April. Diamond stones are weighed in carats (1 carat = 200 milligrams) and in points (1 point = 0.01 carat). In addition to gem-quality stones, several varieties of industrial diamonds occur, and synthetic diamonds have been produced on a commercial scale since 1960. See also industrial diamond; synthetic diamond.

Diamonds are found in three types of deposits: alluvial gravels, glacial tills, and kimberlite pipes. Only in kimberlite pipes, such as those at Kimberley, S.Af., are they present in the original rock in which they were formed, probably lying at depths of more than about 75 miles (120 km). Diamonds found in alluvial and glacial gravels must have been released by fluvial or glacial erosion of the kimberlite matrix and then redeposited in rivers or in glacial till.

Diamonds vary from colourless to black, and they may be transparent, translucent, or opaque. Most diamonds used as gems are transparent and colourless or nearly so. Colourless or pale blue stones are most valued, but these are rare; most gem diamonds are tinged with yellow. A “fancy” diamond has a distinct body colour; red, blue, and green are rarest, and orange, violet, yellow, and yellowish green more common. Most industrial diamonds are gray or brown and are translucent or opaque, but better-quality industrial stones grade imperceptibly into poor quality gems. The colour of diamonds may be changed by exposure to intense radiation (as released in a nuclear reactor or by a particle accelerator) or by heat treatment.

A very high refractive power gives the diamond its extraordinary brilliance. A properly cut diamond will return a greater amount of light to the eye of the observer than will a gem of lesser refractive power and will thus appear more brilliant. The high dispersion gives diamonds their fire, which is caused by the separation of white light into the colours of the spectrum as it passes through the stone.

The scratch hardness of diamond is assigned the value of 10 on the Mohs scale of hardness; corundum, the mineral next to diamond in hardness, is rated as 9. Actually, diamond is very much harder than corundum; if the Mohs scale were linear, diamond's value would be about 42. The hardness of a diamond varies significantly in different directions, causing cutting and polishing of some faces to be easier than others. For detailed physical properties, see native element (table).

In the atomic structure of diamond, as determined by X-ray diffraction techniques, each carbon atom is linked to four equidistant neighbours throughout the crystal. This close-knit, dense, strongly bonded crystal structure yields diamond properties that differ greatly from those of graphite, native carbon's other form.

Diamond, Cape, French CAP DIAMANT, promontory in Québec region, southern Québec province, Canada. It is part of the city of Québec and is located west of the confluence of the St. Charles and St. Lawrence rivers. It is the highest point in the headland (333 feet [102 m]) and is crowned by the Citadel, a former military fortress. Toward the St. Lawrence it presents a bold and precipitous front; on the landward side and toward the St. Charles the declivity is more gradual. The cape was named in 1608 by the French explorer Samuel de Champlain, who found quartz crystals resembling diamonds there. Considerable damage and loss of life was suffered in the Lower Town by rock falls from its heights in 1841, 1852, and 1889.

Diamond Area 1 (Namibia): see Sperrgebiet.

diamond cutting, separate and special branch of lapidary art involving five basic steps in fashioning a diamond: marking, cleaving, sawing, girdling, and faceting.

Marking. Marking is done after examining each rough diamond to decide how it should be cut to yield the greatest value. To make this decision, the shape of the rough diamond and the number and location of imperfections must be considered. Of utmost importance is the determination of the direction of the cleavage, or grain, in the diamond crystal (because of its atomic structure, diamond can be cleaved in four directions parallel to the octahedron crystal faces). Taking these factors into account, the planner decides how the diamond should be cut and marks it to indicate where the stone should be cleaved or sawed.

Cleaving. If the planner's decision is to cleave the stone, it then goes to the cleaver. Large diamonds are often reshaped by cleaving into pieces suitable for sawing. When the stone is very large and valuable, the cleaving is a most critical process, because a mistake by the planner or the cleaver can shatter the stone. The cleaver cuts a groove along the line showing where the stone is to be cleaved, using another diamond as a cutting tool. He mounts the diamond in a holder called a dop and inserts a steel wedge into the groove. He strikes the wedge sharply with a mallet and the diamond splits along its cleavage.

Sawing. The third step, or the second step if cleaving is unnecessary, in the diamond-cutting process is sawing. The saw is a paper-thin disk of phosphor bronze, rotated on a horizontal spindle at about 4,000 revolutions per minute. The sawyer mounts the diamond in a dop and clamps it so that it rests on top of the blade. The rim of the saw is charged with diamond dust, and, as the sawing progresses, the blade continues to recharge itself with diamond from the crystal being cut. The saw will cut through a 1-carat rough diamond in four to eight hours, unless it strikes a knot, in which case it may take much longer.

Girdling. The next step in cutting a round stone is called girdling (rounding; bruting). The diamond to be girdled is placed in the chuck of a lathe; while it spins, a second diamond mounted in a dop on the end of a long handle is held against it, and the diamond is slowly rounded into a cone shape. Some fancy-cut stones are girdled by mounting them off-centre in the lathe chuck.

Faceting. From the girder the diamond goes to the lapper, or blocker, who specializes in placing the first 18 main facets on a brilliant-cut diamond. It then goes to the brillianteer, the worker who places and polishes the remaining 40 facets, if the stone is being cut in the standard 58-facet brilliant cut. Placing and polishing are done by setting the stone either in a lead dop or a mechanical clamp and holding it down on a revolving cast-iron lap (horizontal, circular disk) that has been charged with diamond dust. Great skill is necessary at every stage, but especially during faceting, because the angles of the facets must be exact in order to yield maximum brilliancy, and their sizes must be accurately regulated to preserve symmetry.

The most popular style of cut is the brilliant cut, a round stone with 58 facets. A single cut is a simple form of cutting a round diamond with only 18 facets. Any style of diamond cutting other than the round brilliant or single cuts is called a fancy cut; important fancy cuts include the marquise, emerald, baguette, heart shape, pear shape, kite, and triangle. The term *melee* is used to describe smaller brilliant-cut diamonds as well as all small diamonds that are used in embellishing mountings for larger gems.

Diamond Harbour, city, southeastern West Bengal state, northeastern India, on both sides

of Hajipur Creek, a tributary of the Hooghly River. It is an agricultural trade centre; rice milling is the chief industry. An important steamer stop, it contains the customhouse and harbour master for ships proceeding up the Hooghly to Calcutta. Just south lies the fort of Chingrikhali. Diamond Harbour has a college affiliated with the University of Calcutta. Pop. (1991 prelim.) 30,260.

Diamond Head, cape and celebrated landmark, in Honolulu county, southeastern Oahu Island, Hawaii, U.S., at the southern edge of Waikiki. An extinct volcanic crater, it was used by the ancient Hawaiians as a burial ground. It became known as Diamond Head in the early 19th century when British sailors mistook some volcanic crystals for diamonds. Leahi Point, its highest spot (761 feet [232 m]), is on the western slope. The interior of the crater (diameter 0.5 mile [0.8 km]), visible from Wilhelmina Rise or Maunalani Heights and accessible by road tunnel, is part of the Fort Ruger military installation and is used for small-arms firing practice. There are exclusive residential areas on its eastern and western slopes.

Diamond Necklace, Affair of the, also called AFFAIR OF THE NECKLACE, scandal at the court of Louis XVI in 1785 that discredited the French monarchy on the eve of the French Revolution. It began as an intrigue on the part of an adventuress, the Countess de La Motte, to procure, supposedly for Queen Marie-Antoinette but in reality for herself and her associates, a diamond necklace worth 1,600,000 livres.

The necklace was the property of the Parisian firm of jewelers Boehmer and Bassenge, who had tried unsuccessfully to sell it, first to Louis XV as a present for his mistress Madame du Barry and later to Louis XVI for the queen. The countess's scheme involved the prestigious Cardinal de Rohan, bishop of Strasbourg, who as French ambassador to Vienna from 1772 to 1774 had aroused the dislike of the queen's mother, the empress Maria Theresa, and who had subsequently incurred the hostility of Marie-Antoinette herself; he was anxious to be restored to favour at the French court.

The Countess de La Motte suggested to the cardinal that the queen wished to acquire the necklace surreptitiously and would be prepared for a formal reconciliation at court if he would facilitate its purchase by negotiating with the jewelers. After reading forged letters supposedly from the queen and after a brief nocturnal interview in the gardens of Versailles with a prostitute disguised as the queen, the cardinal entered into a contract with the jewelers to pledge his credit to pay for the necklace in installments. The imposture came to light, however, when the cardinal failed to raise the first installment in full and the jewelers applied directly to the queen. With the imposture exposed, it was discovered that the necklace that the cardinal had supposed to be in the queen's possession had been broken up and sold in London.

Instead of concealing the intrigue, Louis XVI had the cardinal arrested and imprisoned in the Bastille. The cardinal was tried, along with his alleged accomplices, before the Parlement of Paris. Though he was eventually acquitted of the charge of having fraudulently acquired the necklace (May 31, 1786), he was deprived of all his offices and exiled to the abbey of La Chaise-Dieu in Auvergne. The Countess de La Motte was sentenced to be flogged, branded, and imprisoned for life in the Salpêtrière prison in Paris. She later escaped to England and there published scandalous *Mémoires* vilifying the queen.

Though Marie-Antoinette was guiltless, the scandal confirmed the belief of contemporaries in her moral laxness and frivolity. The arbitrary arrest of the cardinal, the pressure

put on his judges, and his final disgrace deepened the impression of the king's weakness and the autocratic nature of his government. The incident was one of many factors leading to the dissolution of the ancien régime and thus to the French Revolution.

Diamond Sūtra, Sanskrit VAJRACCHEDIKĀ-SŪTRA ("Diamond Cutter Sūtra"), brief and very popular Mahāyāna Buddhist text, widely used in East Asia, and perhaps the best known of the 18 smaller "Wisdom" texts, which together with their commentaries are known as the *Prajñāpāramitā*. It takes the form of a dialogue in the presence of a company of monks and bodhisattvas ("Buddhas-to-be") between the Buddha as teacher and a disciple as questioner. The Chinese translation, *Chin-kang Ching* ("Diamond Sūtra"), appeared about AD 400.

The *Diamond Sūtra* expresses the *Prajñāpāramitā* emphasis upon the illusory nature of phenomena in these words: "Just as, in the vast ethereal sphere, stars and darkness, light and mirage, dew, foam, lightning, and clouds emerge, become visible, and vanish again, like the features of a dream—so everything endowed with an individual shape is to be regarded." As with most of the shorter (and later) *Prajñāpāramitā* texts, the ideas are not argued or explained but boldly stated, often in striking paradoxes, including frequent identification of things with their opposites. Thus, the form of presentation underlines the text's thesis that spiritual realization depends upon transcending rational categories. Partly for this reason the *Diamond Sūtra* is considered the Sanskrit work closest in spirit to the philosophy of Zen.

diamondback moth (*Plutella maculipennis*), species of insect belonging to the family Plutellidae (order Lepidoptera). They resemble ermine moths, but diamondbacks hold their antennae forward when at rest. The adult moths have a wingspan of 15 mm (0.6 inch) and wavy yellow radial lines on the forewings, separating the brown anterior area from the cream-coloured hind edge. When the wings are folded these marks form a distinctive series of yellow diamond-shaped marks on top, for which the species is named. Larvae pupate in silk cocoons spun on the leaf surface of various food plants; they cause considerable destruction of cabbages and allied vegetables in all parts of the world.

diamondbird, also called PARDALOTE, any of several songbirds of the family Dicaeidae (order Passeriformes) with a simple tongue and a thickish, unserrated bill. Most of the seven or

Spotted diamondbird (*Pardalotus punctatus*)
Painting by Albert E. Gilbert

eight species, of the genus *Pardalotus*, which are confined to Australia, have gemlike white spangles on the dark upper parts; all are tiny and stub-tailed. Diamondbirds glean insects from leaves and bark. They nest in tree holes, in crannies of buildings, or in tunnels dug in sandbanks or level ground. The spotted diamondbird (*P. punctatus*), with yellow throat and rump, digs tunnels.

Diana, in Roman religion, goddess of wild animals and the hunt, virtually indistinguishable from the Greek goddess Artemis. Her name is akin to the Latin words *diurn* ("sky") and *dius* ("daylight"). Like her Greek counterpart, she was also a goddess of domestic animals. As a fertility deity she was invoked by women to aid conception and delivery. Though perhaps originally an indigenous woodland goddess, Diana early became identified with Artemis. There was probably no original connection between Diana and the moon, but she later absorbed Artemis' identification with both Selene (Luna) and Hecate, a chthonic (infernal) deity; hence the characterization *triformis* sometimes used in Latin literature.

The most famous place of worship for the Italian goddess was the grove of Diana Nemorensis ("Diana of the Wood") on the shores of Lake Nemi at Aricia, near Rome. This was a shrine common to the cities of the Latin League. Associated with Diana at Aricia were Egeria, the spirit of a nearby stream who shared with Diana the guardianship of childbirth, and the hero Virbius (the Italian counterpart of Hippolytus), who was said to have been the first priest of Diana's cult at Aricia. A unique and peculiar custom dictated that this priest be a runaway slave and that he slay his predecessor in combat.

At Rome the most important temple of Diana was on the Aventine. This temple housed the foundation charter of the Latin League and was said to date back to King Servius Tullius (6th century BC). In her cult there Diana was also considered the protector of the lower classes, especially slaves; the Ides (13th) of August, her festival at Rome and Aricia, was a holiday for slaves. Another important centre for the worship of Diana was at Ephesus, where the Temple of Artemis (or Diana) was one of the Seven Wonders of the World. In Roman art Diana usually appears as a huntress with bow and quiver, accompanied by a hound or deer.

Diana, Princess of Wales, original name DIANA FRANCES SPENCER (b. July 1, 1961, Sandringham, Norfolk, Eng.—d. Aug. 31, 1997, Paris, France), former consort (1981–96) of Charles, prince of Wales, and mother of the heir second in line to the British throne, Prince William of Wales (born 1982).

Diana was born at Park House, the home that her parents rented on Queen Elizabeth II's estate at Sandringham and where her childhood playmates were the queen's younger sons, Prince Andrew and Prince Edward. She was the third child and youngest daughter of Edward John Spencer, Viscount Althorp, heir to the 7th Earl Spencer, and his first wife, Frances Ruth Burke Roche (daughter of the 4th Baron Fermoy). She became Lady Diana Spencer when her father succeeded to the earldom in 1975. Riddlesworth Hall (near Thetford, Norfolk) and West Heath School (Sevenoaks, Kent) provided the young Diana's schooling. After attending the finishing school of Chateau d'Oex at Montreux, Switz., Diana returned to England and became a kindergarten teacher at the fashionable Young England school in Pimlico.

She renewed her contacts with the royal family, and her friendship with Charles grew in 1980. On Feb. 24, 1981, their engagement was announced, and on July 29, 1981, they were married in St. Paul's Cathedral in a globally televised ceremony watched by an audience numbering in the hundreds of millions. Their first child, Prince William Arthur Philip Louis of Wales, was born on June 21, 1982, and their second, Prince Henry Charles Albert David, on Sept. 15, 1984. Marital difficulties led to a separation between Diana and Charles in 1992, though they continued to carry out

their royal duties and jointly participate in raising their two children. The couple were divorced on Aug. 28, 1996, with Diana receiving a substantial settlement.

Diana, Princess of Wales, 1993
J.S. Library International

After the divorce, Diana maintained her high public profile and continued her work for charitable causes, including the arts, children's issues, and AIDS patients. Her unprecedented popularity as a member of the royal family, both in Britain and throughout the world, attracted considerable attention from the press, and she became one of the most photographed women in the world. Although she used that celebrity to great effect in promoting her charitable work, the often intrusive activities of the media—and in particular the freelance photographers known as paparazzi—were cited as a factor contributing to her death, and that of her companion and a driver, in an automobile accident as they attempted to evade the journalists' pursuit. Diana was remembered as the "people's princess" by British Prime Minister Tony Blair; her funeral services were watched on television by millions.

bow of the goddess Diana. The diana monkey is generally found well above the ground in West African rain forests. Its face and much of its fur is black. It has a white beard, chest, and throat; a white stripe along each thigh; and a deep reddish patch on the back. It is whitish,

yellowish, or reddish on the inside of the thighs. The rolaway monkey (*C. d. rolaway*) subspecies has a longer beard and broader diadem (browband). The diana monkey is active, hardy, and readily tamed. It is engaging when young but is less friendly when adult. See also guenon.

Diane DE FRANCE, DUCHESSE (duchess) DE MONTMORENCY ET ANGOULÊME (b. 1538, Paris, France—d. Jan. 11, 1619, Paris), natural daughter (legitimized) of King Henry II of France by a young Piedmontese, Filippa Duc. (Diane was often thought, however, to have been the illegitimate daughter of Diane de Poitiers.) She was known for her culture and intelligence as well as for her beauty and for the influence that she wielded during the reigns of Henry III and Henry IV.

Diane was legitimized in 1547. She married Orazio Farnese, duke di Castro, in 1553, but he was killed in battle the same year. In 1559 she married François de Montmorency, eldest son of Anne, constable of France. During

Diane de France, detail from a portrait by an unknown artist, 1568; Louvre, Paris

H. Roger-Viollet

Charles IX's reign she helped to make her husband a leader of the Politiques, a moderate Roman Catholic group working for peace within the realm.

Widowed a second time in 1579, Diane enjoyed even greater influence with Henry III and in 1582 received the duchy of Angoulême in appanage (life estate). She did much to influence the king's reconciliation with Henry of Navarre and was in great favour with the latter when he became king (as Henry IV). Further, she acted as mother to her niece Charlotte de Montmorency, later princess de Condé, with whom Henry IV fell in love. Diane's letters have been saved, and they show her to have been a woman of great tolerance and courage.

Diane DE POITIERS, DUCHESSE (duchess) DE VALENTINOIS (b. Sept. 3, 1499—d. April 22, 1566, Anet, France), mistress of Henry II of France. Throughout his reign she held court as queen of France in all but name, while the real queen, Catherine de Médicis, was forced to live in comparative obscurity. Diane seems to have concerned herself with augmenting her income and with making provisions for her family and protégés rather than with public affairs. A beautiful woman with a lively, cultivated mind, she was a friend and patron of poets, including Pierre de Ronsard, and of many artists. The great Renaissance architect Philibert Delorme built her château at Anet, and the Mannerist sculptor Jean Goujon adorned it with his works.

Diane came to court as a lady-in-waiting first to the mother of Francis I, Louise of Savoy, then to Queen Claude. Shortly after

the death of her husband, Louis de Brézé, comte de Maulevrier, in 1531, the prince Henry, then duc d'Orléans and 20 years her junior, fell violently in love with her, and she became his mistress. Even in their own time legends grew up around them. On Henry's death (1559), his wife, Catherine, forced Diane to restore those of the crown jewels Henry had given her and to accept the fortress-like château of Chaumont in exchange for Chenonceaux. Diane retired to Anet. The *Lettres inédites de Diane de Poitiers* were published by G. Guiffrey (1866).

Dianthus, plant genus of the pink family. See pink.

diapason (from Greek *dia pasōn chordōn*: "through all the strings"), in medieval music, the interval, or distance between notes, encompassing all degrees of the scale—*i.e.*, the octave. In French, *diapason* indicates the range of a voice and is also the word for a tuning fork and for pitch.

On the organ, the open and stopped diapason are two basic stops, or ranks of pipes sounding a given tone colour. Open diapason pipes are also known as principals.

diapause, spontaneous interruption of the development of certain animals, marked by reduction of metabolic activity. It is typical of many insects and mites, a few crustaceans and snails, and perhaps certain other animal groups. This period of suspended development is an apparent response to the approach of adverse environmental conditions. It may occur during any life stage but is most common among pupae (*e.g.*, the cocoons of moths).

Diapause sets in when the bodily concentrations of growth and molting hormones decrease, which usually coincides with changes in day length, temperature, or abundance of food. Diapause is genetically determined but may be eliminated experimentally if the animals are raised under constant and favourable environmental conditions.

Diapensiales, order of dicotyledonous flowering plants comprising the family Diapensiaceae, with seven genera of small, evergreen shrubs and basally woody herbs found in Arctic and alpine (high elevation) habitats of Europe, Asia, and the eastern United States.

The plants are characterized by the presence of radially symmetrical, bisexual flowers with five free or fused sepals; five basally fused, overlapping petals, on the surfaces of which are situated five stamens (male pollen-producing structures) that are alternate in position with the petal lobes; and one pistil (female structure) composed of three carpels (ovule-bearing segments) and divided internally into three chambers that contain from few to many ovules each. Occasionally there are five sterile stamens, or staminodes, positioned opposite the petal lobes.

The order is related to the heath order (Ericales), and both orders are considered to have had an evolutionary ancestor in the tea order

(Theales). The genera include *Shortia* (seven or eight species), *Diapensia* (three species), *Schizocodon* (two species), *Berneuxia* (two species), *Diplarche* (two species), *Pyxidanthera* (one or two species), and *Galax* (one species).

The wand-flower, beetleweed, or galax (*Galax urceolata*), native to the southeastern United States, is widely used in the florist trade in wreaths and decorations for its large, stiff, heart-shaped or rounded leaves, which are especially attractive in the autumn when they develop a rich bronze colour. The fringed

Arctic diapensia (*Diapensia lapponica*)

Kitty Kohout from Root Resources—EB Inc

galax (*Shortia soldanelloides*), a small shrub only a few inches tall with nodding, one-inch (2.5-centimetre) flowers, is sometimes grown as a garden ornamental. Species of *Shortia*, *Diapensia*, and *Pyxidanthera* are sometimes grown in wildflower and rock gardens.

diaper, in architecture, surface decoration, carved or painted, generally composed of square or lozenge shapes but also of other simple figures, each of which contains a flower, a spray of leaves, or some such device. The pattern is repetitive and is usually based on a square grid. It was a common form of sculptural wall enrichment in Gothic art. An example is the 14th-century pulpitum, or choir screen, of Lincoln cathedral, Lincolnshire, England.

In Victorian England, attempts were made to reproduce diaper in brickwork, bricks of different colours being used to form bold patterns like pieces of polychrome cross-stitch work. The architect A.W.N. Pugin so embellished his own house, St. Marie's Grange, near Salisbury. This vogue was, in fact, a revival of brick diapering in Tudor times.

diaphragm, dome-shaped, muscular and membranous structure that separates the thoracic (chest) and abdominal cavities in mammals; it is the principal muscle of respiration.

For a depiction of the diaphragm in human anatomy, shown in relation to other parts of the body, see the colour Trans-Vision in the PROPAEDIA: Part Four, Section 421.

The muscles of the diaphragm arise from the lower part of the sternum (breastbone), the lower six ribs, and the lumbar (loin) vertebrae of the spine and are attached to a central tendon. Contraction of the diaphragm increases the internal height of the thoracic cavity, thus lowering its internal pressure and causing inspiration of air. Relaxation of the diaphragm and the natural elasticity of lung tissue and the thoracic cage produce expiration. The diaphragm is also important in expulsive actions—*e.g.*, coughing, sneezing, vomiting, crying, and expelling feces, urine,

and, in parturition, the fetus. The diaphragm is pierced by many structures, notably the esophagus, aorta, and inferior vena cava, and is occasionally subject to herniation (rupture). Spasmodic inspiratory movement of the diaphragm produces the characteristic sound known as hiccupping.

diapir (from Greek *diaperein*, "to pierce"), geological structure consisting of mobile material that was forced into more brittle surrounding rocks, usually by the upward flow of material from a parent stratum. The flow may be produced by gravitational forces (heavy rocks causing underlying lighter rocks to rise), tectonic forces (mobile rocks being squeezed through less mobile rocks by lateral stress), or a combination of both. Diapirs may take the shape of domes, waves, mushrooms, teardrops, or dikes. Because salt flows quite readily, diapirs are often associated with salt domes or salt anticlines; in some cases the diapiric process is thought to be the mode of origin for a salt dome itself.

diarchy: see dyarchy.

Diarmid MacMURCHADA: see Dermot MacMurrrough.

diarrhea, also spelled DIARRHOEA, abnormally swift passage of waste material through the large intestine, with consequent discharge of loose feces from the anus. Diarrhea may be accompanied by cramping. The disorder may have a wide range of causes. It may, for example, result from dysentery, either amoebic or bacillary; from eating coarse or highly seasoned foods or drinking large quantities of alcoholic beverages; from poisons such as arsenic or mercury bichloride; or from drugs administered to reduce high blood pressure. It may be one consequence of a psychoneurosis. Thyrotoxicosis (exophthalmic goitre), deficiency of parathyroid hormones, and uremia—an excess of nitrogenous wastes in the blood—all may cause diarrhea.

Diarthrognathus, genus of extinct, advanced mammal-like reptiles found as fossils in Late Triassic terrestrial deposits in southern Africa (the Triassic Period began 225,000,000 years ago and lasted 35,000,000 years). *Diarthrognathus* was contemporaneous with a host of other mammal-like reptiles but is nearer than many of them to the line leading to the true mammals because of its unspecialized features

Diarthrognathus skull

of skeletal anatomy and dentition. The articulation of the lower jaw with the skull shares reptilian and mammalian characteristics.

diary, form of autobiographical writing, a regularly kept record of the diarist's activities and reflections. Written primarily for the writer's use alone, the diary has a frankness that is unlike writing done for publication. Its ancient lineage is indicated by the existence of the term in Latin, *diarium*, itself derived from *dies* ("day").

The diary form began to flower in the late Renaissance, when the importance of the in-

dividual began to be stressed. In addition to their revelation of the diarist's personality, diaries have been of immense importance for the recording of social and political history. *Journal d'un bourgeois de Paris*, kept by an anonymous French priest from 1409 to 1431 and continued by another hand to 1449, for example, is invaluable to the historian of the reigns of Charles VI and Charles VII. The same kind of attention to historical events characterizes *Memorials of the English Affairs* by the lawyer and parliamentarian Bulstrode Whitelocke (1605–75) and the diary of the French Marquis de Dangeau (1638–1720), which spans the years 1684 to his death. The English diarist John Evelyn is surpassed only by the greatest diarist of all, Samuel Pepys, whose diary from Jan. 1, 1660 to May 31, 1669, gives both an astonishingly frank picture of his foibles and frailties and a stunning picture of life in London, at the court and the theatre, in his own household, and in his Navy office.

In the 18th century, a diary of extraordinary emotional interest was kept by Jonathan Swift and sent to Ireland as *The Journal to Stella* (written 1710–13; published 1766–68). This work is a surprising amalgam of ambition, affection, wit, and freakishness. The most notable English diary of the late 18th century was that of the novelist Fanny Burney (Madame d'Arbly); it was published in 1842–46. James Boswell's *Journal of a Tour to the Hebrides* (1785), a genuine diary though somewhat expanded, was one of the first to be published in its author's lifetime.

Interest in the diary increased greatly in the first part of the 19th century, in which period many of the great diaries, including Pepys's, were first published. Those of unusual literary interest include the *Journal* of Sir Walter Scott (published in 1890); the *Journals* of Dorothy Wordsworth (published after her death in 1855), which show her influence on her brother William; and the diary of Henry Crabb Robinson (1775–1867), published in 1869, with much biographical material on his literary acquaintances, including Goethe, Schiller, Wordsworth, and Coleridge. The posthumous publication of the diaries of the Russian artist Marie Bashkirtseff (1860–84) produced a great sensation in 1887, as did the publication of the diary of the Goncourt brothers, beginning in 1888.

In the 20th century, the *Journal of Katherine Mansfield* (1927), the two-volume *Journal* of André Gide (1939, 1954), and the five-volume *Diary of Virginia Woolf* (1977–84) are among the most notable examples.

Dias, Antônio Gonçalves (Brazilian writer); see Gonçalves Dias, Antônio.

Dias, Bartolomeu, Dias also spelled DIAZ (b. c. 1450—d. May 29, 1500, at sea, near Cape of Good Hope), Portuguese navigator and explorer who led the first European expedition to round the Cape of Good Hope (1488), opening the sea route to Asia via the Atlantic and Indian oceans. He is usually considered to be the greatest of the Portuguese pioneers who explored the Atlantic during the 15th century.

Almost nothing is known of Dias' early life. His supposed descent from one of Prince Henry the Navigator's pilots is unproved, and his rank was the comparatively modest one of squire of the royal household. The name Dias de Novais does not appear in contemporary documents but only in the deed of appointment of his grandson as governor of Angola in 1571.

In 1474, King Afonso V entrusted his son, Prince John (later John II), with the supervision of Portugal's trade with Guinea and the exploration of the western coast of Africa.

John sought to close the area to foreign shipping and after his accession in 1481 ordered new voyages of discovery to ascertain the southern limit of the African continent. The navigators were given stone pillars (*padrões*) to stake the claims of the Portuguese crown. Thus one of them, Diogo Cão, reached the Congo and sailed down the coast of Angola to Cape Santa Maria at 13°26' S, where he planted one of John's markers, supposing that he had attained the southernmost tip of Africa. Cão was ennobled and rewarded and sailed again: this time he left a marker at 15°40' and another at Cape Cross, continuing to 22°10' S. Royal hopes that he would reach the Indian Ocean were disappointed, and nothing more is heard of Cão. John II entrusted command of a new expedition to Dias. In 1486 rumour arose of a great ruler, the Ogané, far to the east, who was identified with the legendary Christian ruler Prester John. John II then sent Pêro da Covilhã (*q.v.*) and one Afonso Paiva overland to locate India and Abyssinia and ordered Dias to find the southern limit of Africa.

Dias' fleet consisted of three ships, his own "São Cristóvão," the "São Pantaleão" under his associate João Infante, and a supply ship under Dias' brother, whose name is variously given as Pêro or Diogo. The company included some of the leading pilots of the day, among them Pêro de Alenquer and João de Santiago, who earlier had sailed with Cão. A 16th-century historian, João de Barros, places Dias' departure in August 1486 and says that he was away 16 months and 17 days, but since two other contemporaries, Duarte Pacheco and Christopher Columbus, put his return in December 1488, it is now usually supposed that he left in August 1487.

Dias passed Cão's marker, reaching the "Land of St. Barbara" on December 4, Walvis Bay on December 8, and the Gulf of St. Stephen (Elizabeth Bay) on December 26. After Jan. 6, 1488, he was prevented by storms from proceeding along the coast and sailed south out of sight of land for several days. When he again turned to port, no land appeared, and it was only on sailing north that he sighted land on February 3. He had thus rounded the Cape without having seen it. He called the spot Angra de São Brás (Bay of St. Blaise, whose feast day it was) or the Bay of Cowherds, from the people he found there. Dias' Negro companions were unable to understand these people, who fled but later returned to attack the Portuguese. The expedition went on to Angra da Roca (present-day Algoa Bay). The crew was unwilling to continue, and Dias recorded the opinions of all his officers, who were unanimously in favour of returning. They agreed to go on for a few days, reaching Rio do Infante, named after the pilot of "São Pantaleão"; this is almost certainly the present Great Fish (Groot-Vis) River.

It was now clear that India could be reached by the Cape route, and Dias turned back. He sighted the Cape itself in May. Barros says that he named it Cape of Storms and that John II renamed it Cape of Good Hope. Duarte Pacheco, however, attributes the present name to Dias himself, and this is likely since Pacheco joined Dias at the island of Príncipe. Little is known of the return journey, except that Dias touched at Príncipe, the Rio do Resgate (in the present Liberia), and the fortified trading post of Mina. One of Dias' markers, at Padrão de São Gregório, was retrieved from False Island, about 30 miles short of the Great Fish River, in 1938. Another marker once stood at the western end of the Gulf of St. Christopher, since renamed Dias Point.

Nothing is known of Dias' reception by John II. Although plans are said to have been made for a voyage to India, none was attempted for nine years, perhaps pending news of Pêro da Covilhã. John's successor, Manuel I, authorized Vasco da Gama's celebrated voyage

of 1497. Bartolomeu Dias accompanied that expedition as far as Mina.

On da Gama's return to Portugal, after successfully making contact with the seaports of western India, a further fleet was at once organized: it consisted of a dozen ships and was intended to impress the Indians and to open commerce on a large scale. The fleet was under the command of Pedro Álvares Cabral, and Dias was given one of the smaller ships. The fleet sailed far into the western Atlantic on its way to the Cape and sighted land at Espírito Santo in Brazil. Thought to be an island, it was named the Land of the True Cross. Dias thus participated in the discovery of Brazil. He was lost at sea when they reached the Cape, thus perishing in the very waters he had been the first to navigate.

No portrait of Dias is known. He had a son, Antônio, and his grandson, Paulo Dias de Novais, governed Angola and became the founder of the first European city in southern Africa, São Paulo de Luanda, in 1576.

(H.V.L.)

BIBLIOGRAPHY. Sources for Dias are the 16th-century historians: João de Barros, Galvão, and Duarte Pacheco Pereira. See also Eric Axelson, *South-East Africa, 1488–1530* (1940).

Dias, Dinis (fl. 15th century), Portuguese navigator and explorer, one of the sea captains sent by Prince Henry the Navigator to open trade with countries of Africa, the Middle East, and India.

As captain of a caravel in 1445, Dias sailed past the outflowing mouth of the river of Senegal, later discovering Cape Verde, the westernmost point of Africa. Dias chose the name "Green Cape" because the headland had tall trees and fragrant vegetation. Dias and his crew were repulsed by natives when they tried to land and soon returned to Portugal.

In 1446 Prince Henry formed a fleet of caravels that were to show the Portuguese flag along the African coast and explore the river of Senegal, which the Portuguese believed was the western branch of the Nile. Dias commanded one of the vessels.

Diaspora (Greek: Dispersion), Hebrew GALUT (Exile), the dispersion of Jews among the Gentiles after the Babylonian Exile; or the aggregate of Jews or Jewish communities scattered "in exile" outside Palestine or present-day Israel. Although the term refers to the physical dispersal of Jews throughout the world, it also carries religious, philosophical, political, and eschatological connotations, inasmuch as the Jews perceive a special relationship between the land of Israel and themselves. Interpretations of this relationship range from the messianic hope of traditional Judaism for the eventual "ingathering of the exiles" to the view of Reform Judaism that the dispersal of the Jews was providentially arranged by God to foster pure monotheism throughout the world.

The first significant Jewish Diaspora was the result of the Babylonian Exile (*q.v.*) of 586 BC. After the Babylonians conquered the Kingdom of Judah, part of the Jewish population was deported into slavery. Although Cyrus the Great, the Persian conqueror of Babylonia, permitted the Jews to return to their homeland in 538 BC, part of the Jewish community voluntarily remained behind.

The largest, most significant, and culturally most creative Jewish Diaspora in early Jewish history flourished in Alexandria, where, in the 1st century BC, 40 percent of the population was Jewish. Around the 1st century AD, an estimated 5,000,000 Jews lived outside Palestine, about four-fifths of them within the Roman Empire, but they looked to Palestine as the centre of their religious and cultural life. Diaspora Jews thus far outnumbered the Jews in Palestine even before the destruction of Jerusalem in AD 70. Thereafter, the chief centres of Judaism shifted from

country to country (e.g., Babylonia, Persia, Spain, France, Germany, Poland, Russia, and the United States), and Jewish communities gradually adopted distinctive languages, rituals, and cultures, some submerging themselves in non-Jewish environments more completely than others. While some lived in peace, others became victims of violent anti-Semitism.

Jews hold widely divergent views about the role of Diaspora Jewry and the desirability and significance of maintaining a national identity. While the vast majority of Orthodox Jews support the Zionist movement (the return of Jews to Israel), some Orthodox Jews go so far as to oppose the modern nation of Israel as a godless and secular state, defying God's will to send his Messiah at the time he has preordained.

According to the theory of *shelilat ha-galut* ("denial of the exile"), espoused by many Israelis, Jewish life and culture are doomed in the Diaspora because of assimilation and acculturation, and only those Jews who migrate to Israel have hope for continued existence as Jews. It should be noted that neither this position nor any other favourable to Israel holds that Israel is the fulfillment of the biblical prophecy regarding the coming of the messianic era.

Although Reform Jews still commonly maintain that the Diaspora in the United States and elsewhere is a valid expression of God's will, the Central Conference of American Rabbis in 1937 officially abrogated the Pittsburgh Platform of 1885, which declared that Jews should no longer look forward to a return to Israel. This new policy actively encouraged Jews to support the establishment of a Jewish homeland. On the other hand, the American Council for Judaism, founded in 1943 but now moribund, declared that Jews are Jews in a religious sense only and any support given to a Jewish homeland in Palestine would be an act of disloyalty to their countries of residence.

Support for a national Jewish state was notably greater after the wholesale annihilation of Jews during World War II. Of the estimated 14 million Jews in the world today, about 4 million reside in Israel, about 4.5 million in the United States, and about 2.2 million in Russia, Ukraine, and other republics formerly of the Soviet Union.

diaspore, white or grayish, hard, glassy aluminum oxide mineral (HALO₂) that is associated with corundum in emery and is widespread in laterite, bauxite, and aluminous clays. It is abundant in Hungary, South Africa, France, Arkansas, and Missouri. Diaspore is dimorphous with boehmite (*i.e.*, it has the same chemical composition but different crystal structure); it does not contain a hydroxyl group (OH) but has cationic hydrogen (H⁺) in twofold coordination with the oxygen atoms. For detailed physical properties, see oxide mineral (table).

diastereoisomer, also spelled DIASTEROMER, either member of a pair of substances that differ with respect to the configurations of their molecules (*i.e.*, stereoisomers) and that lack a mirror-image relationship (*i.e.*, are not enantiomorphs). An example is the pair consisting of either of the two optically active forms of tartaric acid (either the dextrorotatory or levorotatory form) and the optically inactive meso form of the same acid (mesotartaric acid). Unlike enantiomorphs, diastereoisomers need not have closely similar physical and chemical properties; they may differ as greatly as do structural isomers. For example, either of the optically active tartaric acids melts at 187° C (369° F), whereas mesotartaric acid melts at 143° C (290° F).

diastole, in the cardiac cycle, period of relaxation of the heart muscle, accompanied by the filling of the chambers with blood. Diastole is

followed in the cardiac cycle by a period of contraction, or systole (*q.v.*), of the heart muscle. Initially both atria and ventricles are in diastole, and there is a period of rapid filling of the ventricles followed by a brief atrial systole. At the same time, there is a corresponding decrease in arterial blood pressure to its minimum (diastolic blood pressure), normally about 80 mm of mercury in humans. Ventricular diastole again occurs after the blood has been ejected (during ventricular systole) into the aorta and pulmonary artery.

Diastole may also refer to relaxation of contractile vacuoles in protozoa. See also blood pressure.

A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume

diastrophism, also called TECTONISM, large-scale deformation of the Earth's crust by natural processes, which leads to the formation of continents and ocean basins, mountain systems and rift valleys, and other features by mechanisms such as lithospheric plate movement, volcanic loading, or folding.

The study of diastrophism, or tectonic processes, may now be considered as the central unifying movement in late 20th-century geology and geophysics. Tectonic processes chiefly comprise linear or torsional horizontal movements (such as continental drift) and vertical subsidence and uplift of the lithosphere (strain) in response to natural stresses on the Earth's surface such as the weight of mountains, lakes, and glaciers. Subsurface conditions also cause subsidence or uplift, known as epeirogency, over large areas of the Earth's surface without deforming rock strata; such changes include the thickening of the lithosphere by overthrusts of sedimentary strata, changes in rock density of the lithosphere caused by metamorphism or thermal expansion and contraction, increases in the volume of the asthenosphere (part of the upper mantle supporting the lithosphere) caused by hydration of olivine, and orogenic, or mountain-building, movements.

Diatessaron, the four New Testament Gospels compiled as a single narrative by Tatian (*q.v.*) about AD 150. It was the standard Gospel text in the Syrian Middle East until about AD 400, when it was replaced by the four separated Gospels. Quotations from the *Diatessaron* appear in ancient Syriac literature, but no ancient Syriac manuscript now exists. A 3rd-century Greek papyrus fragment was discovered in 1933 at Doura-Europus, northwest of Baghdad, Iraq. Whether the original writing was done in Greek or Syriac is unknown. There are also manuscripts in Arabian and Persian and translations into European languages made during the Middle Ages.

diathermy, form of physical therapy in which deep heating of tissues is accomplished by the use of high-frequency electrical current. American engineer and inventor Nikola Tesla in 1891 first noted that heat resulted from irradiation of tissue with high-frequency alternating current (wavelengths somewhat longer than the longest radio waves) and pointed out its possible medical uses. K.F. Nagelschmidt, a German physician, in 1909 coined the term diathermy, meaning "heating through."

Three forms of diathermy are in wide use by physical therapists in hospitals and clinics: shortwave, ultrasound, and microwave. In shortwave diathermy, the part to be treated is placed between two condenser plates, and the highest temperature is concentrated in the subcutaneous tissues. Shortwave usually is prescribed as treatment for deep muscles and joints and is sometimes used to localize deep inflammatory disease. Ultrasound diathermy uses high-frequency acoustic vibrations; their heating effect increases circulation

and metabolism and speeds up the rate of ion diffusion across cellular membranes. During treatment the apparatus is moved slowly across the surface of the area to be affected. Ultrasound is used to heat selected muscles that are too deep to be significantly affected by surface heating. Microwave diathermy uses radiation of very high frequency and short wavelength similar to that used in microwave ovens; all physiologic responses are due to its heating effect.

Depending on the amount of heat generated, diathermy can be used to merely warm or to destroy tissue. In the first instance, it is particularly beneficial in relieving muscle soreness and sprain. In the second, as an adjunct to surgery, diathermy is used to coagulate, prevent excessive bleeding, and seal off traumatized tissues. It is particularly effective in eye surgery and neurosurgery. Diathermy therapy is also used effectively to treat back pain, to remove warts and moles, and to destroy or localize bacterial infection of tissues. See also physical medicine and rehabilitation.

diatom, any member of the algal division or phylum Bacillariophyta (about 16,000 species) found floating in all the waters of the Earth. Diatoms may be either unicellular or colonial. The silicified cell wall forms a pillbox-like shell (frustule) composed of overlapping halves (epitheca and hypotheca) that contain intricate and delicate markings useful in testing the resolving power of microscope lenses. The beautiful symmetry and design of diatoms justify their title "jewel of the sea."

During reproduction, usually by cell division, the overlapping shell halves separate, and each

Diatom (highly magnified)
Eric Grave—Photo Researchers

secretes a smaller bottom half. Thus, individual diatoms formed from successive bottom halves show a progressive decrease in size with each division. In a few months there can be as much as a 60 percent decrease in size. Periodic spore formation serves to restore the diatom line to its original size.

Diatoms are divided into two orders on the basis of symmetry and shape: the round, non-motile Centrales have radial markings; the elongated Pennales, which move with a gliding motion, have pinnate (featherlike) markings. Food is stored as oil droplets, and the golden-brown pigment fucoxanthin masks the chlorophyll and carotenoid pigments that are also present. Diatoms, among the most important and prolific sea organisms, serve directly or indirectly as food for many animals. Diatomaceous earth, a substance composed of fossil diatoms, is used in filters, insulation, abrasives, paints, and varnishes.

diatomaceous earth, also called KIESELGUHR, light-coloured, porous, and friable sedimentary rock that is composed of the siliceous shells of diatoms, unicellular aquatic plants of microscopic size. It occurs in earthy beds that somewhat resemble chalk, but it is much

lighter than chalk and will not effervesce in acid. Under a high-powered microscope the form of the diatoms can be distinguished. When well hardened, it is called diatomite. Similar siliceous rocks, called radiolarian earth and radiolarite, are formed from the lattice-like opaline skeletons of Radiolaria.

Diatomaceous earth, formerly used principally as a filter in clarifying sugar and syrups, has been adapted to almost all industrial filtration applications, including the processing of oils, alcoholic and nonalcoholic beverages, antibiotics, solvents, and chemicals. A second major use is as a filler or extender in paper, paint, brick, tile, ceramics, linoleum, plastic, soap, detergent, and a large number of other products. It also is used in the insulation of boilers, blast furnaces, and other devices in which high temperatures are maintained; at temperatures higher than 525° C (about 1,000° F) diatomaceous earth is a more efficient insulator than asbestos or magnesia because it is more resistant to shrinkage and does not fail at red heat. Other uses include sound insulation and vehicles for herbicides and fungicides. The oldest and best known commercial use is as a very mild abrasive in metal polishes and toothpaste.

The largest deposit worked in the United States is in northern Santa Barbara County, California, where beds more than 300 metres (1,000 feet) thick extend over several square miles and vary from soft earth to hard, compact rock that can be sawed into blocks; other production has come from Nevada, Washington, and Oregon. Denmark, France, and Russia have well-developed diatomaceous earth industries, and numerous deposits exist in Algeria.

diatonic, in music, originally, one of the three tetrachords basic to ancient Greek theory; more generally, any stepwise arrangement of the seven "natural" pitches forming an octave devoid of chromatic alterations, in particular the major and minor scales that evolved from the medieval and Renaissance church modes in conjunction with the rise of diatonic harmony. The increasing irrelevance of the old modal system caused the 16th-century Humanist Glareanus to propose two additional modes, Aeolian and Ionian, based on A and C, respectively, and identical in every way with the modern major and natural minor.

The major scale consists of two identical disjunct tetrachords, each comprising two whole-tone steps topped by a semitone, while the minor scale in its natural form consists of one tetrachord with the semitone in the middle and another with the semitone at the bottom. Given the crucial importance of the so-called leading tone (the semitone between the seventh and eighth scalar steps) for diatonic harmony, however, natural minor in practice tends to yield to the need for chromatic alteration of the seventh step. The "harmonic" minor that results is, strictly speaking, no longer a diatonic scale, unlike "melodic" minor, which simply borrows its upper tetrachord from the parallel major, *i.e.*, the major scale beginning and ending on the same pitch.

Due to the close, indeed causal connections between diatonic harmony and the major and minor scales, diatonic scale degrees are often built on the corresponding pitches. Thus, the first step is often referred to as the tonic, the second as the supertonic, third as the mediant, fourth as the subdominant, fifth as the dominant, sixth as the submediant, and seventh as the leading tone. However, heptatonic (seven-note) diatonic scales occur also well beyond the confines of Western art music, including European and American folk monophony, as well as African and Asian music, and therefore, the theoretical value of such linguistic

usage is questionable. It should be noted that the rapidly developing instrumental music of 18th- and 19th-century Europe, with its increasing emphasis on expressiveness, favoured chromatic intrusions to the extent that, by the time of Wagner, diatonicism became relegated primarily to the popular and semipopular realms of musical creativity.

Diatryma, extinct, giant flightless bird found as fossils in early Eocene rocks in North America and Europe (the Eocene Epoch began 54,000,000 years ago and lasted 16,000,000 years). *Diatryma* grew to a height of about 2¼ metres (7 feet). Its small wings were of little use for flight, but the legs were massively

Cast reconstruction of *Diatryma*

By courtesy of the American Museum of Natural History, New York

constructed; *Diatryma* was probably a strong and rapid runner. The head was large and supported a powerful beak; *Diatryma* was an active predator, probably feeding on the small mammals.

Diatryma is representative of the Diatrymiformes, a group of large, flightless, predaceous birds that inhabited North America and Europe. In South America a similarly adapted group is characterized by the genus *Phororhacos*, common during the Miocene Epoch (between 7,000,000 and 26,000,000 years ago). It was about 1½ metres (5 feet) in height and also had weakly developed wings, strong legs, a large head, and a powerful beak.

Diavolo, Fra, byname of MICHELE PEZZA (b. April 7, 1771, Itri, near Formia, Kingdom of the Two Sicilies—d. Nov. 11, 1806, Naples), Italian brigand chief who repeatedly fought against the French occupation of Naples; he is celebrated as a popular guerrilla leader in folk legends and in the novels of the French writer Alexandre Dumas *père*.

After committing various crimes, the young Pezza joined the mountain bandits then plundering the Italian countryside. His ferocity earned him the name Fra Diavolo, or Brother Devil, among the victimized peasants. In 1798 Cardinal Fabrizio Ruffo, chief adviser to King Ferdinand IV of Naples, pardoned Diavolo for two murders and hired him to fight the French. Diavolo's men disrupted the French communications but could not prevent the French capture of Naples (January 1799), which was declared the Parthenopean Republic.

Ruffo and Diavolo then went to Calabria, recruiting for their army while pillaging several towns. With the departure of the French, Ruffo, aided by Diavolo, recaptured Naples (June 1799). Encouraged by Queen Maria

Carolina and the royal family's British ally Admiral Lord Nelson, Diavolo led the barbarous reprisals against collaborators with the French. Arrested for having sacked Albano Laziale, Diavolo was pardoned by Ferdinand, who made him a colonel. After receiving a generous pension and a fief from the Queen, he lived under court protection until 1806.

Diavolo then tried to organize resistance against Napoleon's troops, which had once again taken Naples (January 1806). When a price was put on his head, Diavolo was captured and hanged in the public marketplace.

Diaz, Armando (b. Dec. 5, 1861, Naples—d. Feb. 29, 1928, Rome), Italian general who became chief of staff during World War I.

A graduate of the military colleges of Naples and Turin, Diaz served with distinction in the Italo-Turkish War (1911–12). Appointed major general in 1914, he collaborated with Gen. Luigi Cadorna in the reorganization of the Italian Army in preparation for World War I. When Italy entered the war, he was chief of operations under Cadorna and contributed to the Italian victories at Carso and Gorizia (August 1916). Although he directed his armoured corps with skill, the Italians were overwhelmingly defeated by the Austrians at Caporetto (October 1917). He then replaced Cadorna as chief of staff and succeeded in sufficiently stabilizing the Italian Army to repel the Austrian offensive in June 1918 and to mount a strong counteroffensive. Diaz' decisive victory at Vittorio Veneto (Oct. 24–Nov. 3, 1918) signalled the defeat of the Austrian forces.

As a reward he was named *duca della vittoria* ("duke of victory") in 1921 and appointed marshal in 1924. He served as minister of war in the first Fascist Cabinet (1922–24). Poor health, however, forced him to resign and to retire to private life.

Diaz, Bartolomeu (Portuguese explorer): *see* Dias, Bartolomeu.

Díaz, Porfirio (b. Sept. 15, 1830, Oaxaca, Mex.—d. July 2, 1915, Paris), soldier and president of Mexico (1877–80, 1884–1911), who established a strong centralized state that he held under firm control for more than three decades.

A mestizo (part Indian), Díaz was of humble origin. He began training for the priesthood at 15, but upon the outbreak of war with the United States (1846–48) he joined the army. An illustrious military career followed, includ-

Porfirio Díaz

ing service in the War of the Reform (1857–60) and the struggle against the French in 1861–67, when Maximilian became emperor. Earlier (1849), Díaz studied law with the encouragement of the Liberal Benito Juárez, who first became president in 1858.

Díaz resigned his command and went back to Oaxaca when peace was restored but soon became dissatisfied with the Juárez administration. He led an unsuccessful protest against

the 1871 reelection of Juárez, who died the following year. Díaz continued his protests in an unsuccessful revolt against Pres. Sebastián Lerdo de Tejada in 1876, after which he fled to the United States. Six months later, however, he returned and defeated the government forces at the Battle of Teocac (November 1876), and in May 1877 he was formally elected president.

During his first four years in office, Díaz began a slow process of consolidation of power and built up a strong political machine. His administration achieved a few public improvements but was more noted for its suppression of revolts. Having opposed Lerdo's reelection, he decided not to run for another term himself but handpicked his successor, Gen. Manuel González, who also soon dissatisfied him. Therefore, in 1884, Díaz ran for the presidency again and was elected.

Over the course of the next 26 years Díaz produced an orderly and systematic government with a military spirit. He succeeded in destroying local and regional leadership until the majority of public employees answered directly to him. Even the legislature was composed of his friends, and the press was muffled. He also maintained tight control over the courts.

Díaz secured his power by catering to the needs of separate groups and playing off one interest against another. He won the mestizos' support by supplying them with political jobs. The privileged Creole classes were cooperative in return for the government's non-interference in their haciendas and for positions of honour in the administration. The Roman Catholic Church maintained a policy of non-involvement in return for a certain degree of freedom. The Indians, who formed a full third of the population, were ignored.

When Díaz came to power, the Mexican government was in debt and had very little cash reserves; therefore, he enthusiastically encouraged investment by foreigners. Conditions were made so advantageous to the suppliers of capital that Mexican industries and workers alike suffered. Díaz was no economist, but his two principal advisers, Matías Romero and José Y. Limantour (after 1893), were responsible for the influx of foreigners to build railroads and bridges, to dig mines, and to irrigate fields. Mexico's new wealth, however, was not distributed throughout the country; most of the profits went abroad or stayed in the hands of a very few wealthy Mexicans. By 1910 the economy had declined and national revenues were shrinking, which necessitated borrowing. With wages decreasing, strikes were frequent. Agricultural workers were faced with extreme poverty and debt peonage.

On Feb. 17, 1908, in an interview with a reporter for *Pearson's Magazine*, Díaz announced his retirement. Immediately opposition and pro-government groups began to scramble to find suitable presidential candidates. Then, as plans were being formalized, Díaz decided not to retire but to allow Francisco Madero, an aristocratic but democratically inclined reformer, to run against him. Madero lost the election, as was expected; but when he resorted to a military revolution, the government proved surprisingly weak and collapsed. Díaz resigned office on May 25, 1911, and went into exile.

BIBLIOGRAPHY. Paul H. Garner, *Porfirio Díaz* (2001).

Díaz de La Peña, Narcisse-Virgile (b. 1808, Bordeaux, France—d. Nov. 18, 1876, Menton), French painter and lithographer of the group of landscape painters known as the Barbizon school, who is distinguished for his numerous Romantic depictions of the forest of Fontainebleau and his landscape fantasies with mythological figures.

At age 15 Díaz began working as a ceramic painter for the Sèvres porcelain factory. He

studied for a time with the academic painter Alexandre Cabanel. Strongly influenced by Delacroix and the Romantics and attracted by medieval and Middle Eastern art, he often in his early career painted exotic subjects.

About 1840 Díaz began to paint landscapes in the forest of Fontainebleau near the village of Barbizon. These landscapes, which dominated his work for the rest of his career, characteristically have a pervasive sense of the shadowy seclusion of the forest; e.g., "Forest Scene" (1867; St. Louis [Mo.] Art Museum). Dense, vividly coloured foliage is broken by spots of light or patches of sky shining through the branches. During the last 15 years of his life Díaz seldom exhibited publicly. He was helpful and sympathetic to the Impressionists, especially Renoir, whom he met in 1861 painting at Barbizon.

Díaz de Solís, Juan (b. 1470?, Seville, Spain—d. 1516, Río de la Plata, S.Am.), chief pilot of the Spanish navy and one of the first explorers to enter the Río de la Plata estuary in South America.

Díaz de Solís had made a voyage to the Americas in 1508, before being commissioned to lead an expedition to an area 1,700 leagues (about 5,000 miles) south of the Isthmus of Panama and beyond. He led three vessels from Sanlúcar de Barrameda, Spain, on Oct. 8, 1515, with a crew of 70 men and provisions for 2½ years. In February 1516 he reached the estuary of Río de la Plata, which he called Mar Dulce (Fresh Sea). The first island he reached therein was named Martín García, after one of his crewmen who had died. Sailing up the Uruguay River, he landed on the east bank (modern Uruguay) and was attacked by the Charrúa Indians of the region. He and the rest of the landing party, except for one man, Francisco del Puerto, were killed and eaten in sight of the remaining crewmen on shipboard. Puerto was made prisoner and later gave valuable information about the area to Sebastian Cabot, who arrived there in 1526.

Díaz del Castillo, Bernal (b. c. 1495, Medina del Campo, Castile [Spain]—d. 1584, Guatemala), Spanish soldier and author, who took part in the conquest of Mexico.

In 1514 he visited Cuba and five years later accompanied Hernán Cortés to Mexico. In protest against the academic chronicles of sedentary historians he wrote his *Verdadera historia de la conquista de la Nueva España* (1632; "True History of the Conquest of New Spain"; Eng. trans. *The True History of the Conquest of Mexico*), insisting that, as actor and eyewitness, he was better situated to record the truth of the expeditions in their topographical and military details. This "true history," written in an unassuming, colloquial style, has historical and artistic value and is a sourcebook of idiomatic 16th-century Spanish. **BIBLIOGRAPHY.** Herbert Cerwin, *Bernal Díaz: Historian of the Conquest* (1963).

Díaz Ordaz, Gustavo (b. March 12, 1911, Ciudad Serdán, Mex.—d. July 15, 1979, Mexico City), president of Mexico from 1964 to 1970.

A descendant of José María Díaz Ordaz, associate of 19th-century Mexican leader Benito Juárez, Díaz Ordaz was trained as a lawyer and served as supreme court president in his native state of Puebla before being elected to the Mexican Senate in 1946. In 1958 he became federal interior minister and in July 1964 was elected to the presidency as the Partido Revolucionario Institucional candidate to succeed Adolfo López Mateos. Díaz Ordaz's administration emphasized economic development. In 1977 he was ambassador to Spain.

diazepam, tranquillizing drug used orally or by injection for the treatment of anxiety and tension states and as an aid in preoperative and postoperative sedation. Diazepam also is used to treat skeletal muscle spasms. It belongs

to a group of chemically related compounds (including chlordiazepoxide) called benzodiazepines, the first of which was synthesized in 1933. Diazepam, known by several trade names, including Valium, was introduced in 1963.

Side effects of diazepam include drowsiness and muscular incoordination. A degree of physical dependence can result after prolonged use.

Diazepam occurs as colourless crystals, and it is available for use in solution and in tablet form.

diazo compound, any of a class of organic substances that have as part of their molecular structure the characteristic atomic grouping

in which R represents a hydrogen atom or any of a large number of organic groups.

The most common diazo compound is diazomethane, a toxic, explosive yellow gas usually prepared as a solution in ether and often used in laboratory procedures for converting carboxylic acids into their methyl esters or into their homologues.

diazonium salt, any of a class of organic compounds that have the molecular structure

in which R is an atomic grouping formed by removal of a hydrogen atom from an organic compound. Diazonium salts are usually prepared by the reaction (diazotization) of primary amines with nitrous acid; their most striking property is their instability. The aliphatic diazonium salts exist only as transient intermediates, quickly decomposing into a nitrogen molecule and a carbonium ion; certain aromatic diazonium salts are stable enough to be isolated but react readily either by loss of nitrogen or by formation of azo compounds.

Diazonium salts were first obtained from aromatic amines in 1858, and their utility in the preparation of azo compounds was soon recognized by the dye industry. By varying the chemical structures of the amines that are diazotized (the diazo components) and of the compounds with which they react (the coupling components), colours throughout the visible spectrum are imparted to dyes applicable to many types of fibres by several techniques.

The diazonium group can be replaced by numerous atoms or groups of atoms, often with the aid of copper or a copper salt; these reactions make possible the preparation of a wide variety of aromatic derivatives. Chemical reduction of aromatic diazonium salts leads to formation of hydrazine derivatives.

Dib, Mohammed (b. July 21, 1920, Tlemcen, Alg.—d. May 2, 2003, La Celle-Saint-Cloud, near Paris, France), Algerian novelist and poet, author of some 30 books of fiction, poetry, and essays, many of which closely examine contemporary life in Algeria. Widely regarded as Algeria's foremost writer, Dib was best known for an early trilogy—*Le Grande Maison* (1952; "The Great House"), *L'Incendie* (1954; "The Fire"), and *Le Métier à tisser* (1957; "The Loom")—novels that offer a starkly realistic portrayal of Algerian peasants and workers in the years preceding World War II. Dib wrote in French—the language in which he first learned to read. He began writing poetry at age 15. During the war he studied literature at the University of Algeria and served as an interpreter for French and British military units. He later worked as a designer of rugs (1945–47) and as a journalist (1951) before publishing *Le Grande Maison*, his first book. Later novels include *La Danse du roi*

(1968; "The King's Dance"), *Qui se souvient de la mer* (1962; *Who Remembers the Sea*), *Cours sur la rive sauvage* (1964; "Run on the Wild Shore"), *Dieu en Barbarie* (1970; "God in Barbary"), *Le Maître de chasse* (1973; "The Hunt Master") and *Habel* (1977). These novels—often marked by the use of symbol, myth, and allegory—address subjects such as the French colonial repression of the Algerians, the war for independence and its effects, and the new Algeria after independence. Expelled from Algeria by the colonial authorities in 1959, Dib was eventually allowed to settle in France after fellow writers Albert Camus and André Malraux petitioned the government on his behalf. Dib's volumes of poetry include *Ombre gardienne* (1961; "Guardian Shadow"), *Formulaires* (1970; "Forms"), *Omneros* (1975; Eng. trans. *Omneros*), and *O vive* (1987), and his collections of short stories include *Au café* (1956), *Le Talisman* (1966), and *La Nuit sauvage* (1985; *The Savage Night*). Among his collections of essays are *Tlemcen ou les lieux d'écriture* (1994) and *L'Arbre à dire* (1998). *L.A. Trip*, a verse novel, was published in 2003. In 1994 Dib became the first North African writer to win the Francophone Grand Prix—the Academie Française's highest literary award.

Dibā al-Hiṣn, Dibā also spelled DIBBAH, or DABĀ, settlement and port town, on the eastern (Gulf of Oman) coast of the Oman Promontory of the Arabian Peninsula. It is situated on Dibā Bay and is surrounded by mountains. The town and its locality are part of two countries: the old port area and territory immediately south belong to the United Arab Emirates (Sharjah and Fujairah emirates), while the territory north of the bay lies in the Sultanate of Oman.

An important port of pre-Islāmic Arabia, Dibā al-Hiṣn was traditionally renowned as a copper-exporting centre for the interior of Oman. It was a prosperous town at the time of the emergence of Islām and was one of the last important places of resistance to the new religion in the Arabian Peninsula. It was razed by the Muslims in the 7th century. In the 19th century the Qawāsīm pirate chieftain Sulṭān ibn Saqr gave the town as a fiefdom to one of his sons; his descendants, at various periods, claimed to be independent sheikhs.

Dibā al-Hiṣn, now a small fishing village with adjacent palm groves and vegetable plots, has a central electricity supply and a small hospital. Roads and trails link it with coastal settlements to the south and with the Ras al-Khaimah emirate, across the Oman Promontory. Pop. (latest est.) 18,600.

Dibāng Valley, region, northeastern Arunāchal Pradesh state, eastern India. The region is located in the Great Himalayan Mountain Range, with its northern and eastern reaches fronting Tibet. The Mishmi Hills, a southward extension of the Himalayas, compose most of the northern part of the region. They have an average elevation of 15,000 feet (4,500 m) and are dotted with passes such as Yonggyap at 13,000 feet (3,950 m) and Kaya at 15,600 feet (4,750 m). The region derives its name from the Dibāng River. The Dibāng, together with the Ahui, Emra, Adzon, and Dri streams, flows southward to join the Brahmaputra River. Subtropical evergreen forests of oak, maple, juniper, and pine cover the hilly parts of the region.

The Mishmi, Miju, Idu (Chulikatta), Khampti, and Singpho ethnic groups inhabit the region and speak dialects of the Tibeto-Burman linguistic family. Rice, corn (maize), millet, potatoes, and cotton are grown on the terraced hill slopes and in the more level patches bordering the rivers. Barter markets are important to the regional economy; the Mishmi trade

musk, beeswax, ginger, and chilies with the people of the Assam Plains to the south. Deposits of clay, graphite, limestone, and copper are worked. Cottage industries include caneworking, cloth weaving, silverworking, and blacksmithing. The system of roads in the Dibāng Valley region is largely undeveloped. Most distances are traveled over simple tracks, though there are a few all-weather roads. Anini is the chief settlement in the region. The Igu, a somber dance performed by the Idu Mishmi priests, is closely associated with the region.

dibatag, also called CLARK'S GAZELLE (*Ammodorcas clarkei*), slender north African antelope, family Bovidae (order Artiodactyla), that lives alone or in small groups in grass and thorn brush. The dibatag is a long-legged,

Dibatag (*Ammodorcas clarkei*)
Painting by Donald C. Meighan

long-necked animal with rounded ears, small hooves, and a long, thin black tail that it holds erect or tipped forward when alarmed or running. Shoulder height is 75–90 cm (30–35 inches). The coat is purplish brown with white on the underparts and buttocks and white and reddish brown markings on the face. The male has curved horns that hook forward at the ends. Like the gerenuk, which it resembles, the dibatag browses on foliage and sometimes stands on its hind legs to reach leaves.

dibbuk: see dybbuk.

Dibdin, Charles (baptized March 15, 1745, Southampton, Hampshire, Eng.—d. July 25, 1814, London), composer, author, actor, and theatrical manager whose sea songs and operas made him one of the most popular English composers of the late 18th century.

A chorister at Winchester Cathedral, Dibdin went to London at age 15, worked for a music publisher, and began his stage career at Richmond in 1762. He later acted in London, notably as Ralph in Samuel Arnold's *The Maid of the Mill*. His first operetta, *The Shepherd's Artifice*, was produced at Covent Garden in 1764. By 1778, when he became composer to Covent Garden, he had produced eight operas, among them *The Padlock* (1768), *The*

Charles Dibdin, portrait by T. Phillips, 1799; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

Waterman (1774), and *The Quaker* (1775). He managed the Royal Circus, later the Surrey Theatre, during 1782–84 and in 1785 produced his ballad opera *Liberty Hall*. After the failure of a projected trip to India, he began about 1789 to produce his celebrated one-man "table entertainments," in which he acted as author, singer, and accompanist. Most of his sea songs were written for these entertainments, among them "Tom Bowling" (written in memory of his brother), "To Bachelors' Hall," "Poor Jack," and "'Twas in the Good Ship Rover."

A self-taught musician, Dibdin wrote about 100 stage works, about 1,400 songs, often to his own words, and some instrumental works. He also wrote several novels. Restless, irascible, flagrantly racist, and frequently in debt (for which he fled to France on one occasion and later spent time in debtor's prison), he was a born melodist who excelled in writing for the voice.

Dibdin, Thomas Frognall (b. 1776, Calcutta, India—d. Nov. 18, 1847, London, Eng.), English bibliographer who helped to stimulate interest in bibliography by his own enthusiastic though often inaccurate books, by his share in founding the first English private publishing society, and by his beautifully produced catalog of Lord Spencer's library (which collection later became the nucleus of the John Rylands Library, Manchester). His sailor father was the inspiration for his uncle Charles's song "Tom Bowling."

Both of Dibdin's parents died on the passage from India to England in 1780, and at the age of four he became the ward of his mother's younger brother, Charles Compton. Educated at St. John's College, Oxford, Dibdin began a legal career but took orders in 1805. His *Introduction to the knowledge of rare and valuable editions of the Greek and Latin Classics* (1802) attracted the notice of Lord Spencer, through whose patronage Dibdin obtained a clerical appointment in London. His *Bibliotheca Spenceriana* (1814–15) became famous for the high quality of its printing. Dibdin traveled widely in search of books and manuscripts, and his *Bibliographical, Antiquarian and Picturesque Tour in France and Germany* (1821) is typical of his work in containing much lively anecdote, many factual errors, and some excellent engravings. His *Bibliomania* (1809) contributed to the public's interest in old and rare books. Among his many other works is the two-volume autobiography *Reminiscences of a Literary Life* (1836).

Dibelius, Martin (b. Sept. 14, 1883, Dresden, Ger.—d. Nov. 11, 1947, Heidelberg, W.Ger.), German biblical scholar and pioneer of New Testament form criticism (the analysis of the Bible's literary forms).

Dibelius was educated at several German universities and taught from 1910 to 1915 at the University of Berlin before becoming professor of New Testament exegesis and criticism at Heidelberg, a post he held until his death. His major work, *Die Formgeschichte des Evangeliums* (1919; "Form Criticism of the Gospels"; Eng. trans., *From Tradition to Gospel*), presented an analysis of the Gospels in terms of oral traditions. The earliest form of the Gospels, he proposed, consisted of short sermons; the needs of the Christian community determined the development of written Gospels from these early preachings. His analysis of the Acts of the Apostles showed that the Gospel-writer Luke had access to written records of St. Paul and may have been Paul's companion.

Throughout his writings, Dibelius pursued the origins of ethical statements found in the New Testament and other early Christian writings. His approach was well-received in Germany, and all of his major works were translated into English.

Dibner, Bern (b. Aug. 18, 1897, Lisianka, Ukraine, Russian Empire—d. Jan. 6, 1988, Wilton, Conn., U.S.), American engineer and historian of science.

Dibner arrived in the United States in 1904. After graduating from the Polytechnic Institute of Brooklyn (now Polytechnic University), New York City, in 1921, he worked with the Electric Bond and Share Company (1923–25), where he participated in work leading to the electrification of Cuba. In 1924 he founded the Burndy Engineering Company (now Burndy Corporation) to manufacture solderless electrical connectors that he had invented. He retired in 1972.

Dibner was noted as a historian of science. He established two extensive book collections—the Dibner Library of the History of Science and Technology (1975), a 10,000-volume collection now located at the Smithsonian Institution's National Museum of American History in Washington, D.C., and the Burndy Library (1935), a 40,000-volume collection in Norwalk, Conn. In 1972 the Dibner Institute for the History of Science and Technology was established at Brandeis University in Waltham, Mass.

Dibon, modern DHĪBĀN, ancient capital of Moab, located north of the Arnon River in

Cast of the Moabite Stone, front view
By courtesy of the Oriental Institute, University of Chicago

west-central Jordan. Excavations conducted there since 1950 by the archaeologists affiliated with the American School of Oriental Research in Jerusalem have uncovered the remains of several city walls, a square tower, and numerous buildings. The pottery found on the site dates from Early Bronze (c. 3200–c. 2300 BC) to Early Arabic (c. 7th century AD), although pottery dating from the Middle and Late Bronze ages (c. 2300–c. 1550 BC; c. 1550–c. 1200 BC) is very rare, thus adding weight to the modern assumption that a great part of Transjordan reverted to nomadism during that time.

One of the most important finds at Dibon was the discovery in 1868 of the so-called Moabite Stone, bearing an inscription of Mesha, king of Moab, about the 9th century BC; its 34-line inscription commemorates a victory over the Israelites that reestablished the independence of Moab.

dibromoethane: see ethylene bromide.

Dibrugarh, town, northeastern Assam state, northeastern India. Dibrugarh is situated along the Brahmaputra River and is an important commercial centre, a port, and a rail terminus. Its industries include tea processing and rice and oilseed milling. The Assam Medical College, a law college, and other colleges are affiliated with Dibrugarh University. The town is served by Mohanbāri airfield, 12 miles (19 km) east. Dibrugarh suffered heavy damage from an earthquake in 1950.

North of Dibrugarh, the Dihāng River turns southwestward, where it is joined by the Dibāng and Luhit rivers; from this confluence the river is known as the Brahmaputra. East of Dibrugarh lie part of the Assam Himalayas. The area in which Dibrugarh is situated receives heavy rainfall and is often subject to flooding. Tea growing is among the most important agricultural activities. Petroleum production and coal mining are also carried on in the region on a modest scale. Pop. (1991) 120,127.

dibs (game): see jackstones.

Dibutades (Greek sculptor): see Butades of Sicyon.

Dicaearchus (fl. c. 320 BC), Greek Peripatetic philosopher of Messina in Sicily, a pupil of Aristotle and a scholar of wide learning who influenced such people as Cicero and Plutarch. He spent most of his life in Sparta. Neglecting systematic philosophy, he cultivated special branches of knowledge, including the history of literature and of music, biography, political science, and geography. He also wrote *Bios Hellados* ("Life of Greece"), a history of Greek civilization from its beginning.

Dicaeidae, songbird family, of the order Passeriformes, including the diamondbird and flowerpecker (*qq.v.*) groups.

dicastery, a judicial body in ancient Athens. Dicasteries were divisions of the Heliæa from the time of the democratic reforms of Cleisthenes (c. 508–507 BC), when the Heliæa was transformed from an appellate court to the court with original jurisdiction. Annually 6,000 citizens were chosen to sit on dicasteries, or court panels, and probably represented a cross section of the free population. Each group of about 500 dicasts (about 200 in matters of private law) constituted a court for the entire year. In more important cases, several dicasteries might be combined. The verdict was determined by majority vote; a tie vote acquitted.

Litigants usually spoke for themselves, though advocates could also speak on behalf of a defendant. Before c. 378 BC, evidence was presented orally; thereafter, a written brief was read before the court by its clerk. Once they had been determined, verdicts were not subject to appeal or revision. The presiding officer of the court supervised only procedural matters; the dicasts were judges of both law and fact and voted on the verdict without discussion among themselves.

The dicastery system has been defended on the grounds that the large number of dicasts provided solidarity against intimidation, lessened the chances of bribery, and made the administration of justice a more democratic process.

dice, singular **DIE**, small cubes used as implements for gambling and the playing of social games. Each side of a standard die is marked with from one to six small dots (spots). The spots are arranged in conventional patterns and placed so that together with the spots on the opposite sides they always total seven: one

and six, two and five, three and four. The combinations of the six spots plus the number of dice in play determine the mathematical probabilities.

In most games played with dice, the dice are thrown (rolled, flipped, shot, tossed, or cast) from the hand or from a receptacle called a dice cup, in such a way that they will fall at random. The spots that face upward when the dice come to rest are the deciding spots. The combined number of the spots on the topmost surfaces of the dice decides, according to the rules of the game being played, whether the thrower (called the shooter) wins, loses, continues to throw, or loses possession of the dice to another shooter.

For individual dice games, see Craps; Bank Craps; Barbooth; Chuck-a-Luck; Grand Hazard; Hazard.

History. Sophocles reported that dice were invented by one Palamedes, a Greek, during the siege of Troy, while Herodotus maintained that they were invented by the Lydians in the days of King Atys. Both "inventions" have been discredited by numerous archaeological finds demonstrating that dice were used in many earlier societies. Dice were originally magical devices that primitive people used for the casting of lots to divine the future. The probable forerunners of dice were knucklebones (the anklebones of sheep) marked on four faces.

The people of many early cultures, including those of the North American Indian, the Aztec and Maya, the South Sea islander, the Eskimo, and the African, gambled with dice of many materials and curious shapes and markings. Dice have been made of plum and peach stones; seeds; buffalo, caribou, and moose bone; deer horn; pebbles; pottery; walnut shells; and beaver and woodchuck teeth. In later Greek and Roman times, although most dice were made of bone and ivory, others were of bronze, agate, rock crystal, onyx, jet, alabaster, marble, amber, porcelain, and other materials.

Cubical dice with markings practically equivalent to those of modern dice have been found in Chinese excavations from 600 BC and in Egyptian tombs dating from 2000 BC. In India, more than 2,000 years ago, the first written records of dice are found in the ancient Sanskrit epic the *Mahābhārata*. Pyramidal, pentahedral, and octahedral dice with a great variety of face designs also are and have been used.

Dice are the oldest gaming implements known to man, and countless games are and

(Top) Egyptian die, reputed to be from the tomb of Osiris, Abydos, Egypt; (right and bottom) Etruscan dice, c. 7th–6th century BC, from Chiusi, Italy

By courtesy of the Department of Anthropology, Smithsonian Institution, Washington D C

have been played with them. In Backgammon and hundreds of board games, two or more dice are thrown to determine moves.

Manufacture. Modern dice are almost all made of a cellulose or other plastic material. There are two kinds: perfect, or casino, dice made by hand and true to a tolerance of .0005 inch (.0013 cm), which are used mostly in gambling casinos to play Craps, and round-cornered, or imperfect, dice called drug-store or candystore dice, which are machine-made and are used to play social and board games.

Cheating with dice. Dice specially made for cheating have been found in the tombs of ancient Egypt and the Orient and in prehistoric graves of North and South America. Any die that is not a perfect cube will not act according to correct mathematical odds and is called a shape. Shapes are cubes that have been shaved down on one or more sides so that they are slightly brick-shaped and will tend to settle down most often on their larger surfaces. Shapes are the most common of all crooked dice. Loaded dice when measured with calipers may prove to be perfect cubes, but extra weight just below the surface on some sides will make the opposite sides come up more often than they should.

Dice with one or more faces each duplicated on its opposite side and certain numbers omitted will produce some numbers in disproportionate frequency and never produce certain others. Such dice, called tops and bottoms, are used as a rule only by accomplished dice cheats, who introduce them into the game by sleight of hand.

Dicentra, genus of flowering plants of the fumitory family (Fumariaceae) that includes such popular wild garden representatives as bleeding heart, Dutchman's-breeches, and squirrel corn (*qq.v.*).

Dacey, Albert Venn (b. Feb. 4, 1835, near Lutterworth, Leicestershire, Eng.—d. April 7, 1922, Oxford), jurist whose *Lectures Introductory to the Study of the Law of the Constitution* (1885) is itself considered part of the British constitution, which is an amalgam of several written and unwritten authorities. For this treatise he drew on his knowledge of constitutionalism in the United States as well as in Great Britain.

Dacey taught law at the University of Oxford (1882–1909) and served as principal of the Working Men's College, London (1899–1912). Between 1886 and 1913 he wrote four books opposing Home Rule for Ireland. In 1905 he published his *Lectures on the Relation Between Law and Public Opinion in England During the Nineteenth Century*.

dichlorobenzene, any of three isomeric substances produced by the chlorination of benzene or chlorobenzene in the presence of iron(III) chloride. All three are colourless, denser than water, and insoluble in it. They belong to the family of organic halogen compounds.

The reaction of benzene with chlorine in the presence of iron(III) chloride replaces the hydrogen atoms by chlorine atoms. The first product is chlorobenzene (C₆H₅Cl); and continued treatment with chlorine leads to *ortho*- and *para*-dichlorobenzene (C₆H₄Cl₂), but very little of the *meta* isomer is formed. The *ortho* and *para* isomers can be separated by fractional freezing: upon cooling the mixture, the *para* isomer crystallizes while the *ortho* isomer remains liquid and drains away; *meta*-dichlorobenzene may be prepared from the other isomers by heating them under pressure with aluminum chloride. When the chlorination is conducted under strong illumination and without iron(III) chloride or a similar catalyst, the reaction yields benzene hexachloride

(*q.v.*) instead of chlorobenzene or polychlorobenzenes.

Ortho- or 1,2-dichlorobenzene is a mobile liquid that is used as a solvent, as an insecticide, and in the manufacture of other chemicals, particularly dyestuff intermediates. *Meta*- or 1,3-dichlorobenzene also is a liquid. *Para*- or 1,4-dichlorobenzene is a crystalline solid that has a strong camphorlike odour and is widely used as a moth repellent. The *para* isomer is the most easily isolated of the dichlorobenzenes and was first described in 1864; the *ortho* and *meta* isomers were not recognized until 1875.

dichloromethane: see methylene chloride.

Dichondra, also called LAWN-LEAF, any of several species of low, creeping plants of the morning glory family (Convolvulaceae) that are used in warm climates as grass substitutes. The plants are from 2½ to 8 cm (1 to 3 inches) high and spread by runners.

D. carolinensis, native to southeastern North America, is so similar to the Old World *D. repens* that it is sometimes given as *D. repens* variety *carolinensis*. Its round, bright-green leaves, indented where they join the long stalks, are 2 cm broad.

dichroite (mineral): see cordierite.

Dick, George Frederick (b. July 21, 1881, Fort Wayne, Ind., U.S.—d. Oct. 10, 1967, Palo Alto, Calif.), American physician and pathologist who, with his wife, Gladys Henry

George Frederick Dick, detail of a portrait by an unknown artist

By courtesy of the Department of Special Collections, the University of Chicago Library

Dick, discovered the cause of, and devised means of preventing, scarlet fever.

Dick studied scarlet fever while serving in the Army Medical Corps in World War I. After the war he was professor of clinical medicine at Rush Medical College, Chicago (1918–33), and head of the department of medicine at the University of Chicago (1933–45).

In 1923 he and his wife isolated the hemolytic streptococcus bacterium that causes scarlet fever, prepared the toxin (Dick toxin) used for immunization, and devised the Dick method for prevention of the disease by toxin-antitoxin injection. In 1924 they developed the Dick skin test for susceptibility to scarlet fever.

Dick, Philip K., in full PHILIP KINDRED DICK (b. Dec. 16, 1928, Chicago, Ill., U.S.—d. March 2, 1982, Santa Ana, Calif.), American science-fiction writer whose novels and short stories often depict the psychological struggles of characters trapped in illusory environments.

Dick worked briefly in radio before studying at the University of California, Berkeley, for one year. The publication of his first story, "Beyond Lies the Wub," in 1952 launched his full-time writing career. He published his first novel, *Solar Lottery*, three years later. Early in Dick's work the theme emerged that would remain his central preoccupation—that of a reality at variance with what it appeared or was intended to be. In such novels as *Time out of Joint* (1959), *The Man in the High Castle* (1962; Hugo Award winner), and *The Three*

Stigmata of Pabner Eldritch (1965), the protagonists must determine their own orientation in an "alternate world." Beginning with *The Simulacra* (1964) and culminating in *Do Androids Dream of Electric Sheep?* (1968; adapted for film as *Blade Runner*, 1982), the illusion centres on artificial creatures at large in a real world of the future.

Among Dick's numerous story collections are *A Handful of Darkness* (1955), *The Variable Man and Other Stories* (1957), *The Preserving Machine* (1969), and the posthumously published *I Hope I Shall Arrive Soon* (1985). Several of his short stories have been adapted for film, including "We Can Remember It for You Wholesale" (filmed as *Total Recall*, 1990) and "Second Variety" (filmed as *Screamers*, 1995).

dickcissel (*Spiza americana*), American bird usually placed in the subfamily Cardinalinae of the family Fringillidae (the Emberizidae of some authors). The male dickcissel—named for its song—is a streaky brown bird 16 cm (6.5 inches) long, with a black bib on its yellow breast, looking somewhat like a miniature meadowlark. Dickcissels are seedeaters. They

Dickcissel (*Spiza americana*)

Thase Daniel

breed in weedy fields of the central United States and winter in northern South America; some stray to the Atlantic coast in winter.

Dicke, Robert H., in full ROBERT HENRY DICKE (b. May 6, 1916, St. Louis, Mo., U.S.—d. March 4, 1997, Princeton, N.J.), American physicist noted for his theoretical work in cosmology and investigations centring on the general theory of relativity. He also made a number of significant contributions to radar technology and to the field of atomic physics.

Dicke received a bachelor's degree from Princeton University (1939) and a doctorate from the University of Rochester (1941). In 1941 he became a staff scientist at the radiation laboratory of MIT. Dicke joined the Princeton faculty in 1946; he became emeritus professor in 1984.

During the early 1940s Dicke and other researchers at the Massachusetts Institute of Technology (MIT) played a key role in the development of microwave radar. He himself invented various microwave-circuit devices and radar systems, including mono-pulse radar and coherent pulse radar. In 1944 he developed a microwave radiometer that has become an integral component of most modern radio telescopes. For the next 10 years or so, Dicke devoted much attention to microwave atomic spectroscopy, conducting extensive research on fundamental radiation processes. His work led him to formulate what is often considered the first quantum theory of the emission of coherent radiation. (This type of radiation consists of electromagnetic waves, such as those in a beam of laser light, that are in phase.)

By the 1960s Dicke had become actively interested in gravitation. He carried out a series of studies on the subject, the most notable of which was an experiment testing the principle of equivalence (*i.e.*, that the gravitational mass of a body is equal to its inertial mass) that

forms the cornerstone of Einstein's concept of gravitation—the general theory of relativity. High-precision experiments with this objective had first been performed by the Hungarian physicist Roland von Eötvös, who confirmed the principle to an accuracy of one part in 10^8 . Dicke improved upon Eötvös' accuracy by another factor of 1,000. Together with Carl Brans he investigated the idea of a changing gravitational constant, which had first been proposed in 1937 by Paul Dirac. Dicke and Brans developed a theory of gravitation in which, as a result of the expansion of the universe, the gravitational constant is not actually a constant but decreases at a rate of two parts in 10^{11} per year.

In 1964 Dicke and several colleagues hypothesized that the entire universe is pervaded by a background radiation of microwave wavelengths—the remnant of the intense thermal radiation associated with the apparent explosive origin of the cosmos (see big-bang model). They were unaware that the existence of such residual radiation of the primordial fireball had been postulated some 16 years earlier by George Gamow, Ralph Alpher, and Robert Herman. Before Dicke attempted any observational work, Arno Penzias and Robert Wilson of Bell Telephone Laboratories discovered a faint glow of microwave radiation closely matching that predicted by theory.

Dickens, Charles, in full CHARLES JOHN HUFFAM DICKENS (b. Feb. 7, 1812, Portsmouth, Hampshire, Eng.—d. June 9, 1870, Gad's Hill, near Chatham, Kent), English novelist, generally considered the greatest of the Victorian era. His many volumes include such works as *The Old Curiosity Shop* (1841), *A Christmas Carol* (1843), *Martin Chuzzlewit* (1844), *A Tale of Two Cities* (1859), and *Great Expectations* (1861).

A brief treatment of Charles Dickens follows. For full treatment, see MACROPAEDIA: Dickens.

The insecurity of Dickens' childhood, and in particular his labour in a squalid factory, permanently shaped his view of life and his writing. After serving as a solicitor's clerk, he worked as a reporter, successively, in the law courts, in Parliament, and on London newspapers.

Dickens' career as a writer of fiction began in 1833 with short stories and essays in periodicals, and in 1837 his comic novel *The Pickwick Papers* (originally serialized in 20 monthly installments) made him the most popular author of his time in England. In *Oliver Twist*, *Nicholas Nickleby* (serialized 1837–39 and 1838–39, respectively) and subsequent novels in the 1840s, his heightened concern with vulgarity and evil coexists with his basic optimism, which appears in perhaps its purest form in the semiautobiographical *David Copperfield* (1850). Afterward, however, from *Bleak House* (1853) through *Our Mutual Friend* (1865), the harsher aspects of Victorian industrial society become predominant, the comic spirit is subdued and the satire more biting. During this period he separated from his wife and began a protracted affair with a young actress. Beginning in 1858 he achieved great popularity for his public readings, which he imbued with intense emotional involvement.

Dickey, Bill, byname of WILLIAM MALCOLM DICKEY (b. June 6, 1907, Bastrop, La., U.S.—d. Nov. 12, 1993, Little Rock, Ark.), professional baseball catcher who played for the American League New York Yankees (1928–43, 1946) and competed in eight World Series, seven of which the Yankees won.

Dickey played sandlot ball as a boy, first as a pitcher. The Yankees signed him to a contract in 1925 and after three seasons of minor league play brought him up to the parent club in 1928. Dickey threw right-handed and batted left-handed and had a .313 lifetime batting

average. As a catcher he was consistent and durable, catching 100 games or more per season in 1929–41 and leading American League catchers in fielding for six seasons. He had a fine knowledge of batters and could catch all varieties of pitches. Dickey was at his best in big games: he caught every inning of his 38 World Series games and had a series average of .400 (.438 in the 1932 series). After retiring as a player he was player-manager (1946), catching coach (1949), and scout and coach (1959–60). In 1954 he was elected to the Baseball Hall of Fame. Later he sold securities in Little Rock, Ark.

Dickey, James, in full JAMES LAFAYETTE DICKEY (b. Feb. 2, 1923, Atlanta, Ga., U.S.—d. Jan. 19, 1997, Columbia, S.C.), American poet, novelist, and critic best known for his poetry combining themes of nature mysticism, religion, and history and for his novel *Deliverance* (1970).

Dickey attended Clemson College, South Carolina, before serving as a fighter-bomber pilot in the U.S. Army Air Forces during World War II. After the war he earned B.A. (1949) and M.A. (1950) degrees from Vanderbilt University, Nashville, Tenn. He reentered military service as an Air Force training officer during the Korean War.

By his own account, Dickey began writing poetry at the age of 24 with little awareness of formal poetics. After pursuing graduate studies and working for a time in advertising, he published his first book of poems, *Into the Stone*, in 1960. He was a teacher and writer-in-residence at a number of American universities and colleges, including the University of South Carolina (from 1968). From 1966 to 1968 he served as poetry consultant to the Library of Congress.

Dickey's other collections of poetry include *Drowning with Others* (1962), *Helmets* (1964), *Buckdancer's Choice* (1965), *Poems 1957–1967* (1967), *The Zodiac* (1976), and *The Whole Motion* (1992; collected poems, 1949–92). Of his works of nonfiction prose, *Babel to Byzantium: Poets & Poetry Now* (1968), the autobiographical *Self-Interviews* (1970), and *Jericho: The South Beheld* (1974) are notable. His best-known novel, *Deliverance*, is a harrowing account of a disastrous canoe trip four men take down a river in Georgia. A highly successful film version of the novel was produced from Dickey's own screenplay in 1972.

His poetry is noted for its lyrical portrayal of a world in conflict—predator with prey, soldier with soldier, the self with itself.

Dickinson, city, seat (1884) of Stark county, western North Dakota, U.S., on the Heart River. Founded in 1880 on the Northern Pacific Railway and originally called Pleasant Valley Siding, it was renamed in 1883 for Wells S. Dickinson, a former New York state senator. Early Russian and German settlers were attracted to the vicinity by a Roman Catholic mission. Dickinson is the trading centre for a large agricultural area that produces livestock, wheat, and dairy products. The city's economic activities include livestock marketing and meat-packing, creameries, furniture manufacturing, an oil field, and a steel prefabrication plant. Dickinson State University was opened there in 1918 as a state normal school. Patterson Lake, impounded by the Dickinson Dam, a part of the reclamation plan for the Missouri River valley, is just west of the city. Inc. 1919. Pop. (1994 est.) 16,190.

Dickinson, Emily, in full EMILY ELIZABETH DICKINSON (b. Dec. 10, 1830, Amherst, Mass., U.S.—d. May 15, 1886, Amherst), American lyric poet who has been called "the New England mystic" and who experimented with

poetic rhythms and rhymes. Almost all her poetry was published posthumously.

Emily Dickinson was the second of three children. The three remained close throughout their adult lives: her younger sister, Lavinia, stayed in the family home and did not marry, and her older brother, Austin, lived in the house next door after his marriage to a friend of Emily's. Her grandfather, Samuel Fowler Dickinson, had been one of the founders

Emily Dickinson, daguerreotype, c. 1847
Amherst College Library

of Amherst College, and her father, Edward Dickinson, served as treasurer of the college from 1835 to 1872. A lawyer who served one term (1853–55) in Congress, Edward Dickinson was an austere and somewhat remote father, but not an unkind one. Emily's mother, too, was not close to her children.

Emily was educated at Amherst Academy and Mount Holyoke Female Seminary. Mount Holyoke, which she attended from 1847 to 1848, insisted on religious as well as intellectual growth, and Emily was under considerable pressure to become a professing Christian. She resisted, however, and although many of her poems deal with God, she remained all her life a skeptic. Despite her doubts, she was subject to strong religious feelings, a conflict that lent tension to her writings.

Emily began to write verse about 1850, apparently while under the spell of the poems of Ralph Waldo Emerson and Emily Brontë and under the tutelage of Benjamin F. Newton, a young man studying law in her father's office. Only a handful of her poems can be dated before 1858, when she began to collect them into small, handsewn booklets. Her letters of the 1850s reveal a vivacious, humorous, somewhat shy young woman. In 1855 Emily went to Washington, D.C., with her sister to visit their father, who was serving in Congress. During the trip they stopped off at Philadelphia, where she heard the preaching of the noted clergyman, the Reverend Charles Wadsworth, who was to become her "dearest earthly friend." He was something of a romantic figure: a man said to have known great sorrow, whose eloquence in the pulpit contrasted with his solitary broodings. He and Emily exchanged letters on spiritual matters, his Calvinist orthodoxy perhaps serving as a useful foil for her own speculative reasoning. She may also have found in his stern, rigorous beliefs a welcome corrective to the easy assumption of a benign universe made by Emerson and the other Transcendentalists.

In the 1850s Emily began two of her significant correspondences—with Dr. and Mrs. Josiah G. Holland and with Samuel Bowles. The two men were editors of the *Springfield* (Massachusetts) *Republican*, a paper that took

an interest in literary matters and even published verse. The correspondence continued over the years, although in the case of the Hollands most of the letters after the 1850s went to Mrs. Holland, a woman intelligent enough to comprehend Emily's subtleties and witticisms. Emily tried to interest Bowles in her poetry, and it was a crushing blow to her that he, a man of quick mind but conventional literary tastes, failed to appreciate it.

By the late 1850s, when she was writing poems at a steadily increasing pace, Emily Dickinson loved a man whom she called "Master" in three drafts of letters. "Master" does not exactly resemble any of Emily's known friends but may have been Bowles or Wadsworth. This love shines forth in several lines from her poems: "I'm ceded—I've stopped being Thiers," "Tis so much joy! 'Tis so much joy," and "Dare you see a Soul at the White Heat?" to name only a few. Other poems reveal the frustration of this love and its gradual sublimation into a love for Christ and a celestial marriage to him.

The poems of the 1850s are fairly conventional in sentiment and form, but beginning about 1860 they become experimental both in language and prosody, though they owe much to the metres of the English hymn writer Isaac Watts and to Shakespeare and the King James Version of the Bible. Emily's prevailing poetic form was the quatrain of three iambic feet, a type described in one of the books by Watts in the family library. She used many other forms as well, and to even the simpler hymnbook measures she gave complexity by constantly altering the metrical beat to fit her thought: now slow, now fast, now hesitant. She broke new ground in her wide use of off-rhymes, varying from the true in a variety of ways that also helped to convey her thought and its tensions. In striving for an epigrammatic conciseness, she stripped her language of superfluous words and saw to it that those that remained were vivid and exact. She tampered freely with syntax and liked to place a familiar word in an extraordinary context, shocking the reader to attention and discovery.

On April 15, 1862, Emily Dickinson wrote a letter, enclosing four poems, to a literary man, Thomas Wentworth Higginson, asking whether her poems were "alive." Higginson, although he advised Emily not to publish, recognized the originality of her poems and remained her "preceptor" for the rest of her life. After 1862 Emily Dickinson resisted all efforts by her friends to put her poems before the public. As a result, only seven poems were published during her lifetime, five of them in the *Springfield Republican*.

The years of Emily Dickinson's greatest poetic output, about 800 poems, coincide with the Civil War. Although she looked inward and not to the war for the substance of her poetry, the tense atmosphere of the war years may have contributed to the urgency of her writing. The year of greatest stress was 1862, when distance and danger threatened Emily's friends—Samuel Bowles, in Europe for his health; Charles Wadsworth, who had moved to a new pastorate at the Calvary Church in San Francisco; and T.W. Higginson, serving as an officer in the Union Army. Emily also had persistent eye trouble, which led her, in 1864 and 1865, to spend several months in Cambridge, Mass., for treatment. Once back in Amherst she never travelled again and after the late 1860s never left the boundaries of the family's property.

After the Civil War, Emily Dickinson's poetic tide ebbed, but she sought increasingly to regulate her life by the rules of art. Her letters, some of them equal in artistry to her poems, classicize daily experience in an epigrammatic style. For example, when a friend affronted

Emily by sending a letter jointly to her and her sister, she replied: "A Mutual plum is not a plum. I was too respectful to take the pulp and do not like a stone." By 1870 Emily Dickinson dressed only in white and saw few of the callers who came to the homestead; her seclusion was fiercely guarded by her devoted sister. In August 1870 Higginson visited Amherst and described Emily as "a little plain woman" with reddish hair, dressed in white, bringing him flowers as her "introduction" and speaking in a "soft frightened breathless childlike voice."

Her later years were marked with sorrow at the deaths of many people she loved. The most prostrating of these were the deaths of her father in 1874 and her eight-year-old nephew Gilbert in 1883, which occasioned some of her finest letters. She also mourned the loss of Bowles in 1878, Holland in 1881, Charles Wadsworth and her mother in 1882, Otis P. Lord in 1884, and Helen Hunt Jackson in 1885. Lord, a judge from Salem, Mass., with whom Emily fell in love about 1878, had been the closest friend of Emily's father. Emily's drafts of letters to Lord reveal a tender, mature love, which Lord returned. Jackson, a poet and popular novelist, discerned the greatness of Emily's poetry and tried unsuccessfully to get her to publish it.

Soon after her death her sister Lavinia determined to have Emily's poems published. In 1890 *Poems by Emily Dickinson*, edited by T.W. Higginson and Mabel Loomis Todd, appeared. Other volumes of Dickinson poems, edited chiefly by Mabel Loomis Todd, Martha Dickinson Bianchi (Emily's niece), and Millicent Todd Bingham, were published between 1891 and 1957, and in 1955 Thomas H. Johnson edited all the surviving poems and their variant versions.

The subjects of Emily Dickinson's poems, expressed in intimate, domestic figures of speech, include love, death, and nature. The contrast between her quiet, secluded life in the house in which she was born and died, and the depth and intensity of her terse poems, has provoked much speculation about her personality and personal relationships. Her 1,775 poems and her letters, which survive in almost as great a number, reveal a passionate, witty woman and a scrupulous craftsman who made an art not only of her poetry but also of her correspondence and her life.

(D.J.M.H.)

MAJOR WORKS. No collection of poems by Emily Dickinson was published in her lifetime. The first selection, *Poems by Emily Dickinson* (1890), was followed by *Poems: Second Series* (1891), and *Poems: Third Series* (1896). Additional poems were included in *Letters of Emily Dickinson*, 2 vol. (1894). Later volumes of poems were: *The Single Hound: Poems of a Lifetime* (1914), *Further Poems of Emily Dickinson: Withheld from Publication by Her Sister Lavinia* (1929), *Unpublished Poems of Emily Dickinson* (1935), and *Bolts of Melody: New Poems of Emily Dickinson* (1945).

BIBLIOGRAPHY. S.T. Clendenning, *Emily Dickinson: A Bibliography, 1850-1966* (1968), is the most recent and most comprehensive bibliography. The great majority of Dickinson manuscripts, both poems and letters, are in the libraries of Harvard University and Amherst College. Emily Dickinson's home, the property of Amherst College, contains some memorabilia. The basic text of the poems is *The Poems of Emily Dickinson, Including Variant Readings Critically Compared with All Known Manuscripts*, 3 vol., ed. by T.H. Johnson (1955); *Final Harvest: Emily Dickinson's Poems* (1962), 2 vol. ed. by Johnson. *Acts of Light* (1980), a selection of poems with paintings by Ekholm Burket and an appreciation by Jane Langton, marked the Dickinson 150th anniversary. The most complete edition of the letters is *The Letters of Emily Dickinson*, 3 vol., ed. by T.H. Johnson and Theodora Ward (1958). There is as yet no definitive biography of Emily Dickinson. Biographical studies include: M.T. Bingham, *Emily Dickinson's Home: Letters of Edward Dick-*

inson and His Family (1955), the best account to date of Emily Dickinson's early years; T.H. Johnson, *Emily Dickinson: An Interpretive Biography* (1955), an extended critical biography; Jay Leyda, *The Years and Hours of Emily Dickinson*, 2 vol. (1960), a day-by-day guidebook to the life of Emily Dickinson; and Richard B. Sewall, *The Life of Emily Dickinson*, 2 vol. (1974), portrays the relation of her life and her work. Critical studies of the poems are C.R. Anderson, *Emily Dickinson's Poetry: Stairway of Surprise* (1960); G.F. Whicher, *This Was a Poet* (1938), although no longer wholly reliable as biography, is critically excellent; Jean McClure Mudge, *Emily Dickinson and the Image of Home* (1975), combines criticism and biography.

Dickinson, John (b. Nov. 8, 1732, Talbot County, Md., U.S.—d. Feb. 14, 1808, Wilmington, Del.), American statesman often referred to as the "penman of the Revolution."

He studied law in London at the Middle Temple and practiced law in Philadelphia (1757-60) before entering public life. Dick-

John Dickinson, portrait by Charles Willson Peale, 1770; in Independence National Historical Park, Philadelphia

inson represented Pennsylvania in the Stamp Act Congress (1765) and drafted its declaration of rights and grievances. He won fame in 1767-68 as the author of the *Letters from a Farmer in Pennsylvania, to the Inhabitants of the British Colonies*, which appeared in many colonial newspapers. The letters helped turn opinion against the Townshend Acts (1767), under which new duties were collected to pay the salaries of royal officials in the Colonies. He also denounced the establishing of the American Board of Customs Commissioners at Boston to enforce the acts.

Dickinson was a delegate from Pennsylvania in the Continental Congress (1774-76) and was the principal author of the "Declaration . . . Setting Forth the Causes and Necessity of Their Taking Up Arms." He helped prepare the first draft of the Articles of Confederation (1776-77) but voted against the Declaration of Independence (1776) because he still hoped for conciliation with the British. Although he was accused of being a Loyalist, he later served in the patriot militia.

As a delegate from Delaware to the Federal Constitutional Convention (1787), he signed the U.S. Constitution and worked for its adoption. He later defended the document in a series of letters signed "Fabius."

Dickinson College at Carlisle, Pa., chartered in 1783, was named in his honour.

Dickinson, Jonathan (b. April 22, 1688, Hatfield, Mass., U.S.—d. Oct. 7, 1747, Elizabethtown, N.J.), prominent Presbyterian clergyman of the American colonial period and the first president of Princeton University.

Joining the newly founded Presbyterian body in the Middle Colonies in 1717, he soon became a leader in theological thought and debate. When in 1721-29 its synod deliberated over adoption of a constitution, it was largely through Dickinson's efforts that the undefined powers were given to the presbyteries rather

than to the synod, or central body. When the two factions, known as the Old Side and the New Side, differed over the extent to which ministers must accept creedal statements, he

Jonathon Dickinson, oil painting by Edward Ludlow Mooney; in Nassau Hall, Princeton University

proposed a compromise that proved unacceptable, and controversy ensued. The church was further plagued by differences of opinion on the Great Awakening revival of the 1730s and '40s; Dickinson, after some hesitation, gave his support to the group that approved the new movement. In 1746 the New Side founded the College of New Jersey (later Princeton University), and Dickinson served as its first president for the brief period before his death.

dickite, clay mineral, a form of kaolinite (*q.v.*).

Dickson, Carr, also called CARTER DICKSON (American author): see Carr, John Dickson.

Dickson, John Robinson (b. Nov. 15, 1819, Dungannon, Northern Ireland—d. Nov. 23, 1882, Wolfe Island, near Kingston, Lower Canada [now Ontario, Can.]), Irish-born medical doctor and educator who was instrumental in establishing organized medical training in Canada.

Dickson's family immigrated to Upper Canada in 1837, a move that interrupted his medical studies in Glasgow, Scot. He studied for one term at the University of New York, receiving his M.D. degree in 1842. He then returned to Canada and opened a practice in Kingston. Together with a group of colleagues, Dickson proposed a plan for the establishment of a faculty of medicine at Queens College in Kingston; in 1855 the faculty was organized, and Dickson was appointed to teach the principles and practice of surgery. Dickson and others left Queens in 1864 in a dispute with the trustees. Within two years they had established the Royal College of Physicians and Surgeons of Kingston. Dickson also served as the first president of the Council of Medical Education and Registration of Upper Canada. He retired in 1881.

Dickson, Leonard Eugene (b. Jan. 22, 1874, Independence, Iowa, U.S.—d. Jan. 17, 1954, Harlingen, Texas), American mathematician who made important contributions to the theory of numbers and the theory of groups.

Appointed associate professor of mathematics at the University of Texas at Austin in 1899, Dickson joined the staff of the University of Chicago in 1900, where he remained until 1939. A prolific mathematician, Dickson published the first extensive work on the theory of finite fields and expanded the Wedderburn and Cartan theories of linear associative algebras. One of his most-engrossing studies concerned the relationships between the theory of invariants and number theory. Using the analytic results of the Russian mathematician Ivan M. Vinogradov, he proved the ideal Waring theorem in his investigations of additive number theory. Of his 18 published books, the most monumental is *History of the Theory of Numbers*, 3 vol. (1919–23).

dicotyledon, byname DICOT, any plant of the class Magnoliopsida (magnoliatae, Dicotyledones), the larger of the two great groups (the smaller is the Liliopsida, or Monocotyledones) of flowering plants, or angiosperms. There are about 175,000 known species of dicots. Most common garden plants, shrubs and trees, and broad-leaved flowering plants such as magnolias, roses, geraniums, and hollyhocks are dicots. Most dicots are characterized by the presence of a pair of seed leaves, or cotyledons, in the embryo contained in the seed.

Dicots typically also have flower parts (sepals, petals, stamens, etc.) based on a plan of four or five, or multiples thereof, although there are exceptions. The leaves are net-veined in most, which means the vessels that conduct water and food show a meshlike pattern. In the stems the vessels are usually arranged in a continuous ring near the stem surface. About 50 percent of all dicot species are woody; they show an annual increase in stem diameter as a result of the production of new tissue by the cambium, a layer of cells that remain capable of division throughout the life of these

Dicotyledon bean seed
(A) side, (B) edge, (C) opened embryo

plants. Branching of stems is common, as are taproots. The microscopic pores (stomates) on the leaf surfaces are usually scattered and are in various orientations. The pollen grains typically have three germinal furrows or pores (tricolpate condition), except in the more primitive families.

dictating machine, device for recording, storage (usually brief), and subsequent reproduction (usually by typewriter or word-processing system) of spoken messages. Dictating machines may be either mechanical or magnetic and may record the voice on wire, coated tape, or plastic disks or belts, which can be removed from the machine after dictation and forwarded to the point of transcription. The transcribing machine reproduces the dictated message in voice form. Early dictating machines were mechanical and, as in Thomas A. Edison's original invention, phonographically recorded the sound waves of the human voice on a wax cylinder; a similar device played the record back for transcription. Later adaptations used plastic disks and belts, and upon the development of magnetic wire and then tape recording, loops of wire and magnetic disks and belts were used to record. Micro-electronic and solid-state developments have made possible significant reductions in size of both the dictating and playback equipment and the disks or cassettes used. The playback device used by the transcribing typist usually is operated by foot controls.

dictator, in the Roman Republic, a temporary magistrate with extraordinary powers, nomi-

nated by a consul on the recommendation of the Senate and confirmed by the Comitia Curiata (a popular assembly). The dictatorship was a permanent office among some of the Latin states of Italy, but at Rome it was resorted to only in times of military, and later internal, crises. The dictator's term was set at six months, although he customarily laid down his powers as soon as the crisis passed. The consuls and other magistrates continued in office during a dictatorship but were subject to the dictator's authority. By the 3rd century BC the limited term of a dictatorship rendered it impracticable in operations outside of Italy. Moreover, by 300 BC the people had secured the limitation of dictatorial powers by subjecting their use to the right of appeal. Dictators were then named for lesser functions such as the holding of elections in certain cases.

The Carthaginian invasion in the Second Punic War (218–201 BC) spurred a temporary revival of the office, but after 202 no dictators were chosen for any purpose. The dictatorships conferred upon Sulla and Julius Caesar in the last decades of the republic, in the 1st century BC, did not indicate a revival of the former office but the development of an extra-constitutional office with virtually unlimited powers. The term of office was lengthened until Caesar acquired dictatorial powers for 10 years in 46 and for life immediately before his assassination in 44 BC, when the office was abolished. See also tyrant.

dictatorship, form of government in which one person or a small group possesses absolute power without effective constitutional limitations. The term dictatorship comes from the Latin title dictator (*q.v.*), which in the Roman Republic designated a temporary magistrate who was granted extraordinary powers in order to deal with state crises. Modern dictators, however, resemble ancient tyrants rather than ancient dictators. Ancient philosophers' descriptions of the tyrannies of Greece and Sicily go far toward characterizing modern dictatorships. Dictators usually resort to force or fraud to gain despotic political power, which they maintain through the use of intimidation, terror, and the suppression of basic civil liberties. They may also employ techniques of mass propaganda in order to sustain their public support.

With the decline and disappearance in the 19th and 20th centuries of monarchies based on hereditary descent, dictatorship became one of the two chief forms of government in use by nations throughout the world, the other being constitutional democracy. Rule by dictators has taken several different forms. In Latin America in the 19th century, various dictators arose after effective central authority had collapsed in the new nations recently freed from Spanish colonial rule. These caudillos, or self-proclaimed leaders, usually led a private army and tried to establish control over a territory before marching upon a weak national government. Antonio López de Santa Anna in Mexico and Juan Manuel de Rosas in Argentina are examples of such leaders. (See personalismo.) Later 20th-century dictators in Latin America were different. They were national rather than provincial leaders and often were put in their position of power by nationalistic military officers, as was Juan Perón of Argentina. They usually allied themselves with a particular social class, and attempted either to maintain the interests of wealthy and privileged elites or to institute far-reaching left-wing social reforms.

In the new states of Africa and Asia after World War II, dictators quickly established themselves on the ruins of constitutional arrangements inherited from the Western colonial powers that had proved unworkable in

the absence of a strong middle class and in the face of local traditions of autocratic rule. In some such countries, elected presidents and prime ministers captured personal power by establishing one-party rule and suppressing the opposition, while in others the army seized power and established military dictatorships.

The communist and fascist dictatorships that arose in various technologically advanced countries in the first half of the 20th century were distinctively different from the authoritarian regimes of Latin America or the post-colonial dictatorships of Africa and Asia. Nazi Germany under Adolf Hitler and the Soviet Union under Joseph Stalin were the leading examples of such modern totalitarian dictatorships. The crucial elements of both were the identification of the state with a single mass party and of the party with its charismatic leader, the use of an official ideology to legitimize and maintain the regime, the use of terror and propaganda to suppress dissent and stifle opposition, and the use of modern science and technology to control the economy and individual behaviour. (See totalitarianism.) Soviet-type communist dictatorships arose in central and eastern Europe, China, and other countries in the wake of World War II, though most of them (as well as the Soviet Union itself) had collapsed by the last decade of the 20th century.

During times of domestic or foreign crisis, even most constitutional governments have conferred emergency powers on the chief executive, and in some notable cases this provided the opportunity for duly elected leaders to overthrow democracy and rule dictatorially thereafter. The proclamation of emergency rule, for example, was the beginning of the dictatorships of Hitler in Germany, Benito Mussolini in Italy, Kemal Atatürk in Turkey, Józef Piłsudski in Poland, and António de Oliveira Salazar in Portugal. In other democracies, however, constitutional arrangements have survived quite lengthy periods of crisis, as in Great Britain and the United States during World War II, in which the use of extraordinary powers by the executive came to a halt with the end of the wartime emergency.

dictatorship of the proletariat, in Marxist thought, rule by the proletariat (the economic and social class consisting of industrial workers who derive income solely from their labour) during the transitional phase between the abolition of the capitalist system and the establishment of communism. During this transition the proletariat is to suppress bourgeois resistance to its socialist revolution, destroy the social relations of production underlying the class system, and create a classless society.

Originally conceived by Karl Marx as a dictatorship by the majority class, it became in Russia (after October 1917) a dictatorship of a political party that claimed to represent the proletariat.

diction, choice of words, especially with regard to correctness, clearness, or effectiveness. Any of the four generally accepted levels of diction—formal, informal, colloquial, or slang—may be correct in a particular context but incorrect in another or when mixed unintentionally. Most ideas have a number of alternate words that the writer can select to suit his purposes. “Children,” “kids,” “youngsters,” “youths,” and “brats,” for example, all have different evocative values.

The widest scope for literary style is offered at the level of word choice. Phrases such as “the little house,” “the diminutive house,” and “the petite house” have overlapping or synonymous meanings; but “little” may suggest endearment as well as size; “diminutive,” good construction; and “petite,” prettiness. Samuel Johnson, who believed that great thoughts

were always general and that it was not the business of poets to “number the streaks of the tulips,” habitually used general, abstract, non-emotive words: “This quality of looking forward into futurity seems the unavoidable condition of a being whose motions are gradual, and whose life is progressive” (*The Rambler*, 1750). Most modern writers, however, prefer particular, concrete, and emotive words and take advantage of the evocative values of technical, dialect, colloquial, or archaic terms when it suits their purpose. George Meredith used the archaic “damsel” to suggest the immaturity of a heroine; Ronald Firbank, in “Mrs. Henedge lived in a small house with killing stairs just off Chesham Place” (*Vain-glory*, 1915), uses “killing” colloquially, in contrast to the standard words around it.

dictionary, reference book that lists words in order and gives their meanings. In dictionaries of Western languages, the words are given in alphabetic order. In addition to its basic function of defining words, a dictionary may provide information about their pronunciation, grammatical forms and functions, etymologies, syntactic peculiarities, variant spellings, conventional abbreviations, and synonyms and antonyms. A dictionary may also provide quotations illustrating a word's use, and these may be dated to show the earliest known uses of the word in specified senses. The word *dictionary* itself comes from the Latin *dictio*, “the act of speaking,” and *dictionarius*, “a collection of words.” It can be said that dictionaries define words while encyclopaedias define things, though there are many encyclopaedias that use the word dictionary in their name (e.g., biographical dictionaries).

A brief treatment of dictionaries follows. For full treatment, see MACROPAEDIA: Encyclopaedias and Dictionaries.

The initial impetus for making dictionaries differed slightly from current principles. The early emphasis was less on making inventories of current word usage than on explaining changes or differences of meaning over centuries and among languages. Greeks in the first century AD made dictionaries to explain obsolete words from their rich literary past. Latin also was preserved in dictionaries, which were of considerable value because most scholarly work in Europe during the Middle Ages was done in Latin. So influential was one such dictionary, compiled by Ambrogio Calipino in 1502, that the name calepino was often substituted for the word dictionary.

The close juxtaposition of so many languages in Europe led to the appearance of many bilingual and polyglot (multilingual) dictionaries from the early Middle Ages. Examples of certain words in the 7th and 8th centuries are the earliest records of English, and for a long while, bilingual dictionaries provided the best explanations of English words. In the 16th and 17th centuries, works appeared combining French, English, Italian, Latin, Spanish, and Welsh in assorted variations. These works reflect the interest in and traffic with continental European cultures and the Renaissance enthusiasm for classical literature. One result was the influx into English of many Greek- and Latin-derived words.

The movement to produce an English dictionary was partly prompted by a desire for wider literacy, so that common people could read Scripture, and partly by a frustration of the educated that no regularity in spelling existed for the English language. Robert Cawdrey borrowed heavily from several earlier sources to make his *A Table Alphabetical* (1604), a 3,000-word list considered to be the first purely English dictionary. Other notable works of the period were John Bullokar's *An English Expositor* (1610) and Henry Cockeram's *The English Dictionarie* (1623), which was the first to actually use the word in its title. Subsequent English dictionaries built on

their predecessors and added innovations such as the inclusion of cant and dialect (Coles, 1676); stressing of word origins, or etymology (Blount, 1656); an abridged dictionary (Kersey, 1708); and accents for pronunciation (Bailey, 1727). In general, English dictionaries were thought to be inferior to those on the continent.

In 1746–47, with the backing of some prominent publishers, the poet and critic Samuel Johnson undertook the most ambitious English dictionary to that time and compiled a list of 43,500 words. The work was fastidious in discerning different senses for words and included 118,000 judiciously chosen illustrative quotations from the best literature of the language. Like many persons both before and after him, Johnson worried that changes in a language caused it to decay and hoped that a dictionary would check that decay. He realized as he worked that “language is the work of man, of a being from whom permanence and stability cannot be derived.” The makers of dictionaries, lexicographers, can only describe current and past language; they cannot prescribe its use.

The spirit that recognized the changes and variations within language led to Noah Webster's dictionary of Americanisms in the early 19th century. Along the same lines was a dictionary of Scotland's language by John Jamieson that used as its source the everyday speech of common people. A further development in the 19th century was the work of philologists like Jacob Grimm and Franz Bopp, who found a systematic connection between most European languages and Sanskrit. The resulting discovery of the Indo-European family of languages changed the nature of etymology.

By the end of the 19th century the immense *Oxford English Dictionary* (*OED*), meant to be a definitive inventory of the English language, was underway. Between 1879 and 1928, when it was finally finished, 15,000 pages, using 1,827,306 illustrative quotations, were compiled. Similar works have been completed in France, Italy, and Germany. The monumental task posed by these immense inventories is updating them as the language changes.

The modern dictionary remains a difficult undertaking, beginning with the task of choosing a word list that will serve its readers well. In the field of science, words are continually coming into existence, and to name even all existing species of living creatures would be prohibitive (there are more than one million known insect species). Lexicographers have come to be regarded as the guardians of the language, which they are not. Language is, by nature, an ever-changing human phenomenon, but social and sometimes political pressures often force dictionary publishers to tailor word lists according to societal preferences. Pronunciation, for example, is enormously variable among speakers, but some guide is necessary because the phonetics of so many English words is variable. In general, the standard dictionary today will provide some uniformity in spelling, aid to pronunciation, a sense of a word's grammatical applications, sense meanings, illustrative quotations, a label that indicates a level of acceptability (for example, regional dialect or vulgar usage), and a word's etymology.

There are various levels of dictionaries, general-purpose being most common. Scholarly dictionaries such as the second edition of the *OED* (1989; known as *OED2*) are more thorough and include exhaustive etymologies as well as obsolete words. Specialized dictionaries cover narrow fields of knowledge, though their contents are still arranged by alphabetic order.

Dictionary of American English on Historical Principles, A (DAE), four-volume dictionary designed to define usage of words

and phrases in American English as it differed from usage in England and other English-speaking countries, as well as to show how the cultural and natural history of the United States is reflected in its language. It was published from 1936 to 1944. Compiled under the editorship of Sir William A. Craigie, who had been a coeditor of *The Oxford English Dictionary*; and James R. Hulbert, an American professor of English, the dictionary includes American words and expressions from the period extending from the first English settlements until the end of the 19th century. It provides dated illustrative quotations for most entries.

Dictionary of Americanisms, A, two-volume dictionary of words and expressions that originated in the United States or that were first borrowed into the English language in the United States. Edited by the American scholar Mitford M. Mathews and published in 1951, the dictionary was based on historical principles and was designed to remedy the omissions and deficiencies of *The Oxford English Dictionary* and the *Dictionary of American English on Historical Principles*. Unlike the latter, which included many words of British origin, *A Dictionary of Americanisms* included only words and expressions of American origin. Sources and authorities were cited under each entry, and the pronunciations of many of the words were given.

Dictionary of the English Language, A, the famous dictionary of Samuel Johnson, published in London in 1755; its principles dominated English lexicography for more than a century. This two-volume work surpassed earlier dictionaries not in bulk but in precision of definition.

Its strength lay in two features: the original, carefully divided and ordered, elegantly formulated definitions of the main word stock of the language; and the copious citation of quotations from the entire range of English literature, which served in support and illustration and which exemplified the different shades of meaning of a particular word.

A Dictionary of the English Language included a history of the language, a grammar, and an extensive list of words representing basic general vocabulary, based on the best conversation of contemporary London and the normal usage of respected writers. The original was followed in 1756 by an abbreviated one-volume version that was widely used far into the 20th century.

Johnson's accomplishment was to provide for the English language a dictionary that incorporated with skill and intellectual power the prevailing ideals and resources and the best available techniques of European lexicography. It was the standard English dictionary until Noah Webster's (1828).

Dictionary of the Irish Language, authoritative dictionary of the Irish language that continues, starting with the letter D, the work of Kuno Meyer's *Contributions to Irish Lexicography* (1906–07), which covered A–C.

Based, according to its subtitle, on Old and Middle Irish materials, it began publication in Dublin in 1913. The collection of the material, which is based on historic principles and will cover the language from its earliest period, has been administered by the Royal Irish Academy. Culled from books, manuscripts, and spoken language, entries describe the development of the meanings of words and their grammatical inflections.

In 1938 the academy began the irregular publication of fascicles continuing the work under the general heading *Contributions to a Dictionary of the Irish Language*. The academy's intent in issuing these fascicles was to make available immediately the enormous amount of material already collected and prepared for the final dictionary.

Dictionnaire alphabétique et analogique de la langue française (French: "Alphabetical and Analogical Dictionary of the French Language"), scholarly historical dictionary of the French language, which supplies for each entry etymology, definition, antonyms, synonyms, and cross-references.

Originally published in six volumes in Paris in 1951–64, the set was reissued with a supplement in 1970. In addition to containing all words accepted by the French Academy, it includes scientific and technical terms, commonly used colloquialisms, and archaic words that appear in classical French literature. Lengthy quotations from contemporary French writers demonstrate historical changes in the use of words and draw on modern-day examples to clarify usage. A one-volume abridgement was first produced in 1967 and revised in several successive editions thereafter.

Dictionnaire de la langue française (French: "Dictionary of the French Language"), also called **DICTIONNAIRE LITTRÉ**, or **LITTRÉ**, monumental French dictionary compiled by Maximilien-Paul-Émile Littré, a French lexicographer.

Begun in 1844 and published in four volumes from 1863 to 1873, with a supplement issued in 1877, it contained many quotations from works of literature written in the 16th–19th century, exhibiting historically the growth of the French language. In it, Littré attempted to classify precisely every sense in which a word could be used. In the arrangement of definitions, the first place is given to the most primitive meaning of the word instead of to the most common one; but other meanings follow in an order that is often logical rather than historical.

A reprint in modern format was published in 1956–58 in seven volumes, with the material from the original supplement incorporated into the alphabetization. This dictionary remains important for its history, etymology, and grammar. Other reissues appeared in 1978 (four volumes) and 1983 (four volumes and a supplement in one volume).

Dictys CRETENSIS, author of a pseudo-chronicle of the Trojan War. Dictys was supposed to have accompanied the Cretan leader Idomeneus from Knossos to the siege of Troy and to have written a pro-Greek account of the Trojan War. His manuscript was said to have been "discovered" during the 1st century AD and, by command of the Roman emperor Nero, to have been transliterated from Phoenician into Greek. Probably in the 4th century one Lucius Septimius put out a translation of Dictys' supposed eyewitness account (which in fact probably dates from the 2nd or 3rd century AD), and this fantastic work, the *Ephemeris belli Trojani*, together with a similar but pro-Trojan account by Dares Phrygius, was a major sourcebook for medieval handlings of the Trojan story.

Dicuil (fl. 825, Ireland), monk, grammarian, and geographer whose work is important to the history of science and is a testament to Irish learning in the 9th century.

Much of Dicuil's astronomical knowledge was gained in calculating dates for religious festivals. Completed in 825, his *De mensura orbis terrae* ("Concerning the Measurement of the World") contains the earliest mention of Irish hermits having visited Iceland (795), where they marveled at the midnight sun. The work also contains the most definite Western reference to the old freshwater canal between the Nile River and the Red Sea, which was blocked up in 767. Dicuil learned of the canal from one "Brother Fidelis," probably another Irish monk, who sailed along the "Nile" into the Red Sea—passing the "Barns of Joseph," or pyramids of Giza, which are well described. Dicuil quotes from, or refers to, 30 Greek and

Latin writers as well as to the poet Sedulius, his Irish contemporary. The best edition of *De mensura* was made by G. Parthey in 1870.

dicyclopentadienyliron (chemistry): *see* ferrocene.

dicyemid, any of a class (Dicyemida) of multicellular wormlike parasites of various marine invertebrates. *See* mesozoan.

Dicynodon, extinct genus of therapsid reptiles, which once were dominant mammallike land vertebrates, found in Upper Permian deposits (*i.e.*, those roughly 245 to 258 mil-

Dicynodon skeleton

By courtesy of the American Museum of Natural History, New York

lion years old) in southern Africa, Europe, and southern Asia. The skull of *Dicynodon* was very long in the region behind the eye, with well-developed ridges that provided attachment for strongly developed jaw muscles. A toothless, beaklike structure was probably covered with a horny material that was also probably present in the remainder of the jaw. Small teeth occurred on some specimens, as did a pair of tusklke canine teeth, which may have been restricted to males. *Dicynodon*, probably herbivorous, had a massive body with strong limbs and limb girdles.

Didachē (Greek: "Teaching"), also called **TEACHING OF THE TWELVE APOSTLES**, the oldest surviving Christian church order, probably written in Egypt or Syria in the 2nd century. In 16 short chapters it deals with morals and ethics, church practice, and the eschatological hope (of the Second Coming of Christ at the end of time) and presents a general program for instruction and initiation into the primitive church.

Some early Christian writers considered the *Didachē* canonical, and Egyptian authors and compilers quoted it extensively in the 4th and 5th centuries. Eusebius of Caesarea quoted it in his *Ecclesiastical History* (early 4th century), and it formed the basis of chapter 7 of the 4th-century *Apostolic Constitutions*, a collection of early Christian ecclesiastical law. It was known only through such references in early Christian works until a Greek manuscript of it, written in 1056, was discovered in Istanbul in 1873 by the metropolitan Philotheos Bryennios. He published it in 1883. Two fragments of the work were later discovered, a 4th-century Greek papyrus in Oxyrhynchus, Egypt, and a 5th-century Coptic papyrus in the British Museum.

The *Didachē* is not a unified and coherent work but a compilation of regulations that had acquired the force of law by usage in scattered Christian communities. Evidently several pre-existing written sources were used and were compiled by an unknown editor.

Chapters 1–6 give ethical instruction concerning the two ways, of life and of death, and reflect an early Christian adaptation of a Jewish pattern of teaching in order to prepare catechumens (candidates for Christian baptism). Chapters 7–15 discuss baptism, fasting, prayer, the Eucharist, how to receive and test traveling apostles and prophets, and the appointment of bishops and deacons. Chapter 16 considers the signs of the Second Coming of the Lord.

Didelot, Charles (-Louis) (b. 1767, Stockholm, Swed.—d. Nov. 7, 1837, Kiev, Ukraine, Russian Empire [now Ukraine]), Swedish-born French dancer, choreographer, and teacher whose innovative work anticipated the Romantic ballet.

Following his debut in 1790 at the Paris Opera with the ballerina Madeleine Guimard, he later turned to choreography, creating several celebrated ballets, including *La Métamorphose*, *Flore et Zéphyre*, *Don Quixote*, and *Apollon et Daphné*. He is credited with important innovations, among them flying dancers via a wiring system, and with major changes in costume (supposedly introducing flesh-tinted tights for ballerinas).

From 1801 to 1811 he was ballet master and choreographer of the St. Petersburg Imperial School of Ballet. After working in London and Paris, he returned (1816) to St. Petersburg for the rest of his life, during which he produced more than 50 ballets that ventured into the Romantic milieu and applied the principles of his teacher, Jean-Georges Noverre. His own teaching method was considered revolutionary; his wife, Mme Rose (Colinette) Didelot, was also a dancer.

Diderot, Denis (b. Oct. 5, 1713, Langres, France—d. July 31, 1784, Paris), French man of letters and philosopher who, from 1745 to 1772, served as chief editor of the *Encyclopédie*, one of the principal works of the Age of Enlightenment.

Youth and marriage. Diderot was the son of a widely respected master cutler. He was tonsured in 1726, though he did not in fact enter the church, and was first educated by the Jesuits at Langres. From 1729 to 1732 he studied in Paris at the Collège d'Harcourt or at the Lycée Louis-le-Grand or possibly at both these institutions, and he was awarded the degree of master of arts in the University of Paris on Sept. 2, 1732. He then studied law as an articulated clerk in the office of Clément de Ris but was more interested in languages, literature, philosophy, and higher mathematics. Of his life in the period 1734 to 1744 comparatively little is known. He dropped an early ambition to enter the theatre and, instead, taught for a living, led a penurious existence as a publisher's hack, and wrote sermons for missionaries at 50 *écus* each. At one time he seems to have entertained the idea of taking up an ecclesiastical career, but it is most unlikely that he entered a seminary. Yet his work testifies to his having gone through a religious crisis, and he progressed relatively slowly from Roman Catholicism to deism and

then to atheism and philosophical materialism. That he led a disordered and bohemian existence at this time is made clear in his posthumously published novel, *Le Neveu de Rameau* (*Rameau's Nephew*). He frequented the coffeehouses, particularly the Régence and the Procépe, where he met the philosopher Jean-Jacques Rousseau in 1741 and established a friendship with him that was to last for 15 years, until it was broken by a quarrel.

In 1741 he also met Antoinette Champion, daughter of a linendraper, and in 1743 he married her—secretly, because of his father's disapproval. The relationship was based on romantic love, but the marriage was not a happy one owing to incompatible interests. The bond held, however, partly through a common affection for their daughter, Angélique, sole survivor of three children, who was born in 1753 and whom Diderot eventually married to Albert de Vandeul, a man of some standing at Langres. Diderot lavished care over her education, and she eventually wrote a short account of his life and classified his manuscripts.

Mature career. In order to earn a living, Diderot undertook translation work and in 1745 published a free translation of the *Inquiry Concerning Virtue* by the 3rd Earl of Shaftesbury, whose fame and influence he spread in France. Diderot's own *Pensées philosophiques* (1746; *Philosophic Thoughts*), an original work with new and explosive anti-Christian ideas couched in a vivid prose, contains many passages directly translated from or inspired by Shaftesbury. The proceeds of this publication, as of his allegedly indecent novel *Les Bijoux indiscrets* (1748), were used to meet the demands of his mistress, Madeleine de Puisieux, with whom he broke a few years later. In 1755 he met Sophie Volland, with whom he formed an attachment that was to last more than 20 years. The liaison was founded on common interests, natural sympathy, and a deepening friendship. His correspondence with Sophie, together with his other letters, forms one of the most fascinating documents on Diderot's personality, enthusiasms, and ideas and on the intellectual society of Louise d'Épinay, F.M. Grimm, the Baron d'Holbach, Ferdinando Galiani, and other deistic writers and thinkers (Philosophes) with whom he felt most at home. Through Rousseau, Diderot met Étienne Bonnot de Condillac, the philosopher, and for a time the three friends dined together at the Panier Fleuri.

The Encyclopédie. In 1745 the publisher André Le Breton approached Diderot with a view to bringing out a French translation of Ephraim Chambers' *Cyclopaedia*, after two other translators had withdrawn from the project. Diderot undertook the task with the distinguished mathematician Jean Le Rond d'Alembert as coeditor but soon profoundly changed the nature of the publication, broadening its scope and turning it into an important organ of radical and revolutionary opinion. He gathered around him a team of dedicated litterateurs, scientists, and even priests, many of whom, as yet unknown, were to make their mark in later life. All were fired with a common purpose: to further knowledge and, by so doing, strike a resounding blow against reactionary forces in church and state. As a *dictionnaire raisonné* ("rational dictionary"), the *Encyclopédie* was to bring out the essential principles and applications of every art and science. The underlying philosophy was rationalism and a qualified faith in the progress of the human mind.

In 1749 Diderot published the *Lettre sur les aveugles* (*An Essay on Blindness*), remarkable for its proposal to teach the blind to read through the sense of touch, along lines that Louis Braille was to follow in the 19th century, and for the presentation of the first step in his evolutionary theory of survival by superior adaptation. This daring exposition of the doc-

trine of materialist atheism, with its emphasis on human dependence on sense impression, led to Diderot's arrest and incarceration in the prison of Vincennes for three months.

Diderot's work on the *Encyclopédie*, however, was not interrupted for long, and in 1750 he outlined his program for it in a *Prospectus*, which d'Alembert expanded into the momentous *Discours préliminaire* (1751). The history of the *Encyclopédie*, from the publication of the first volume in 1751 to the distribution of the final volumes of plates in 1772, was checkered, but ultimate success was never in doubt. Diderot was undaunted by the government's censorship of the work and by the criticism of conservatives and reactionaries. A critical moment occurred in 1758, on the publication of the seventh volume, when d'Alembert resigned on receiving warning of trouble and after reading Rousseau's attack on his article "Genève." Another serious blow came when the philosopher Helvétius' book *De l'esprit* ("On the Mind"), said to be a summary of the *Encyclopédie*, was condemned to be burned by the Parlement of Paris, and the *Encyclopédie* itself was formally suppressed. Untempered by Voltaire's offer to have the publication continued outside France, Diderot held on in Paris with great tenacity and published the *Encyclopédie's* later volumes surreptitiously. He was deeply wounded, however, by the discovery in 1764 that Le Breton had secretly removed compromising material from the corrected proof sheets of about 10 folio volumes. The censored passages, though of considerable interest, would not have made an appreciable difference on the impact of the work. To the 17 volumes of text and 11 volumes of plates (1751–72), Diderot contributed innumerable articles partly original, partly derived from varied sources, especially on the history of philosophy ("Eclectisme" ["Eclecticism"]), social theory ("Droit naturel" ["Natural Law"]), aesthetics ("Beau" ["The Beautiful"]), and the crafts and industries of France. He was moreover an energetic general director and supervised the illustrations for 3,000 to 4,000 plates of exceptional quality, which are still prized by historians today.

Philosophical and scientific works. While editing the *Encyclopédie*, Diderot managed to compose most of his own important works as well. In 1751 he published his *Lettre sur les sourds et muets* ("Letter on the Deaf and Dumb"), which studies the function of language and deals with points of aesthetics, and in 1754 he published the *Pensées sur l'interprétation de la nature* ("Thoughts on the Interpretation of Nature"), an influential short treatise on the new experimental methods in science. Diderot published few other works in his lifetime, however. His writings, in manuscript form, were known only to his friends and the privileged correspondents of the *Correspondance littéraire*, a sort of private newspaper edited by Baron Grimm that was circulated in manuscript form. The posthumous publication of these manuscripts, among which are several bold and original works in the sciences, philosophy, and literature, have made Diderot more highly appreciated in the 20th century than he was in France during his lifetime.

Among his philosophical works, special mention may be made of *L'Entretien entre d'Alembert et Diderot* (written 1769, published 1830; "Conversation Between d'Alembert and Diderot"), *Le Rêve de d'Alembert* (written 1769, published 1830; "D'Alembert's Dream"), and the *Eléments de physiologie* (1774–80). In these works Diderot developed his materialist philosophy and arrived at startling intuitive insights into biology and chemistry; in speculating on the origins of life without divine intervention, for instance, he foreshadowed the evolutionary theories of Charles Darwin and put forth a strikingly prophetic picture of the cellular structure of

Diderot, oil painting by Louis-Michel van Loo, 1767; in the Louvre, Paris

matter. Though Diderot's speculations in the field of science are of great interest, it is the dialectical brilliance of their presentation that is exceptional. His ideas, often propounded in the form of paradox, and invariably in dialogue, stem from a sense of life's ambiguities and a profound understanding of the complexities and contradictions inherent in human nature.

Novels, dialogues, and plays. Four works of prose fiction by Diderot were published posthumously: the novel *La Religieuse* (written 1760, published 1796; *The Nun*); the novel *Jacques le fataliste et son maître* (written 1773, published 1796; *Jacques the Fatalist*); *Le Neveu de Rameau* (written between 1761 and 1774, published in German 1805; *Rameau's Nephew*), a character sketch in dialogue form; and *Supplément au voyage de Bougainville* (written 1772, published 1796; "Supplement to Bougainville's Voyage").

La Religieuse describes the distressing and ultimately tragic experiences of a girl who is forced to become a nun against her will. In *Jacques le fataliste*, Jacques, who believes in fate, is involved in an endless argument with his master, who does not, as they journey along retelling the story of their lives and loves. Diderot's philosophical standpoint in this work is ambivalent, as is his ethical standpoint in *Le Neveu de Rameau*. The latter work is a dialogue between Diderot and a bohemian musician who is based partly on the nephew of the French composer Jean-Philippe Rameau. This work may properly be called a satire, since it challenges the cant of contemporary society and the hypocrisy of its morality. Rameau's nephew is depicted as a shamelessly selfish parasite, an eccentric, and a musician who is gifted yet unable to make his mark through insufficient talent. His dialogue with Diderot is spontaneous and witty, and there are digressions, a lengthy disquisition on contemporary musical controversies, and diatribes against Diderot's own enemies. This brilliantly conceived, highly original and entertaining *divertissement* reveals the complexity of Diderot's personality and of his philosophical ideas. In the *Supplément au voyage de Bougainville* Diderot, in discussing the mores of the South Pacific islanders, emphasizes his conception of a free society based on tolerance and develops his views on sexual freedom.

Diderot's major plays, *Le Fils naturel* (1757; "The Illegitimate Son") and *Le Père de famille* (1758; "The Father of the Family"), make tedious reading today. His theories on drama, however, expounded in *Entretiens sur le fils naturel* (1757; "Discussion on the Illegitimate Son") and *Discours sur la poésie dramatique* ("Discourse on Dramatic Poetry"), were to exercise a determining influence on the German dramatist Gotthold Lessing. Taking as his starting point the *comédie larmoyante*, Diderot stressed the need for greater realism on the stage and favoured the serious bourgeois drama of real life. Characters should be presented against their milieu and belong to specific professions, so that the moral and social implications of the play, which he considered to be of primary importance, should have greater impact. In his *Paradoxe sur le comédien* (written 1773, published 1830), Diderot argued that great actors must possess judgment and penetration without "sensitivity"—i.e., without actually experiencing the emotions they are portraying as characters on the stage. Although Diderot wrote literary criticism, it is as the first great art critic, covering the Paris Salons, or annual art exhibitions, for the *Correspondance littéraire*, that he is best remembered. His analysis of art, artists, and the technique of painting, together with the excellence of his taste and his style, have won him posthumous fame; his *Essai sur la peinture* (written 1765, published 1796; "Essay on Painting"), especially, was admired by Goethe

and later by the 19th-century poet and critic Charles Baudelaire.

Late life and works. The completion of the *Encyclopédie* in 1772 left Diderot without a source of income. To relieve him of financial worry, Catherine the Great of Russia first bought his library through an agent in Paris, requesting him to retain the books until she required them, and then appointed him librarian on an annual salary for the duration of his life. Diderot went to St. Petersburg in 1773 to thank her for her financial support and was received with great honour and warmth. He wrote for her the *Plan d'une université pour le gouvernement de Russie* ("Plan of a University for the Government of Russia"). He stayed five months, long enough to become disillusioned with enlightened despotism as a solution to social ills.

In 1774 Diderot, now old and ill, worked on a refutation of Helvétius' work *De l'homme* (1772; "On Man"), which was an amplification of the destroyed *De l'esprit*. He wrote *Entretien d'un philosophe avec la Maréchale* ("Conversation with the Maréchale") and published in 1778 *Essai sur les règnes de Claude et de Néron* ("Essay on the Reigns of Claudius and Nero"). Usually known as *Essai sur la vie de Sénèque* ("Essay on the Life of Seneca"), the work may be regarded as an apologia for that Roman satirist and philosopher. Diderot's intimate circle was dwindling. Mme d'Épinay and d'Alembert died, leaving only Grimm and Baron d'Holbach. Slowly Diderot retired into the shell of his own personal and family life. The death of Sophie Volland in February 1784 was a great grief to him; he survived her by a few months, dying of coronary thrombosis in the house in the rue de Richelieu that Catherine the Great had put at his disposal. Apocryphally, his last words were: "Le premier pas vers la philosophie, c'est l'incrédulité" ("The first step toward philosophy is incredulity"). Through the intervention of his son-in-law, he was buried in consecrated ground at Saint-Roch.

(Ro.N./Ed.)

BIBLIOGRAPHY. A.M. Wilson, *Diderot*, 2 vol. (1957–72, reissued in 1 vol., 1972), is the standard and most scholarly biography. John Morley, *Diderot and the Encyclopaedists*, 2 vol. (1878, reissued 1971), is still of value. More recent studies include Peter France, *Diderot* (1983); P.N. Furbank, *Diderot: A Critical Biography* (1992); and Stephen Werner, *The Comic Diderot: A Reading of the Fictions* (2000).

didgeridoo, also spelled DIDJERIDU, a dronepipe (wind instrument), or straight wooden trumpet used by northwest Australian Aboriginals. It is made from bamboo or a hollow sapling and is about 5 feet (1.5 m) long. Decorated ceremonial varieties, however, may be two or three times longer.

The didgeridoo has a wax mouthpiece covered with resin, and its end is sometimes placed in a tin can for resonance. It is used in such ritual ceremonies as those for sunsets, circumcisions, and funerals.

Didion, Joan (b. Dec. 5, 1934, Sacramento, Calif., U.S.), American novelist and essayist known for her lucid prose style and incisive depictions of social unrest and psychological fragmentation.

Didion graduated from the University of California, Berkeley, in 1956 and then worked for *Vogue* magazine from 1956 to 1963. Her first novel, *Run River* (1963), examines the disintegration of a California family. A collection of magazine columns published as *Slouching Towards Bethlehem* (1968) established Didion's reputation as an essayist. In a second collection, *The White Album* (1979), Didion continued her analysis of the turbulent 1960s. The inner decay of the Establishment provides a theme for the essays in *After Henry* (1992; also published as *Sentimental Journeys*).

Other works by Didion include the short novels *Play It as It Lays* (1970) and *The Last*

Thing He Wanted (1996) and the essays *Salvador* (1983) and *Miami* (1987). She also wrote several screenplays with her husband, John Gregory Dunne, including *A Star Is Born* (1976; with others).

Didius Julianus, Marcus (b. c. 135—d. June 1, 193), wealthy Roman senator who became emperor (March 28–June 1, 193) by being the highest bidder in an auction for the support of the Praetorian Guard.

A member of one of the most prominent families of Mediolanum (now Milan), Didius Julianus had a long and distinguished public career. After commanding the legion at Mogontiacum (now Mainz), about 167, he governed northeastern Gaul, Dalmatia, the lower Rhine, Bithynia, and Africa.

During the political disturbances of Commodus' reign he was banished to Mediolanum. Commodus was murdered on the eve of Jan. 1, 193, however, and his successor, Pertinax, was assassinated by the imperial guard late in March. Backed by a group of senators who had Milanese connections, Julianus competed with the late emperor's father-in-law, T. Flavius Sulpicianus, in offering the guards a substantial donative (accession bounty). Julianus won the bidding and was escorted by the guards to the Senate, where he encountered angry demonstrators denouncing the auction and calling for the intervention of the army. Shortly thereafter the Danube legions invaded Italy, killed Julianus, and proclaimed their principal commander, Lucius Septimius Severus, emperor.

Dido, also called ELISSA, in Greek legend, the reputed founder of Carthage, daughter of the Tyrian king Muto (or Belus), and wife of Sychaeus (or Acerbas).

Her husband having been slain by her brother Pygmalion, Dido fled to the coast of Africa, where she purchased from a local chieftain, Iarbas, a piece of land on which she founded Carthage. The city soon prospered, and Iarbas sought Dido's hand in marriage. To escape from him, Dido constructed a funeral pyre, on which she stabbed herself before the people. Virgil, however, made Dido a contemporary of Aeneas, whose descendants founded Rome. Dido fell in love with Aeneas after his landing in Africa, and Virgil attributes her suicide to her abandonment by him at the command of Jupiter. Dido was identified with the Virgo Caelestis; i.e., Tanit, the tutelary goddess of Carthage.

Didot FAMILY, family of French printers, publishers, and typefounders who had a profound influence on the history of typography in France.

The founder of the family business was François Didot (1689–1757), who began business as a printer and bookseller in Paris in 1713. He was best known for publishing a 20-volume collection of the works of the Abbé Prévost. Didot's eldest son, François-Ambroise (1730–1804), altered the standard of type design by allowing greater contrast between thick and thin letters. He improved upon the Fournier standard of measurement for punch cutting and mold making; the Didot point system of 72 points to the French inch became the standard unit of type measurement. François-Ambroise also abandoned the use of classical names such as "parisienne" and "petit romain" for type size and instead distinguished types by their size as measured in points (e.g., 12-point or 24-point type). In 1780 he introduced a highly finished wove paper, similar to the kind used by the English typefounder John Baskerville.

François-Ambroise had two sons, Pierre (called Pierre l'aîné; 1761–1853), who took over his father's printing office, and Firmin

(c. 1765–1836), who assumed responsibility for his father's typefoundry. Pierre published acclaimed editions of Virgil, Horace, La Fontaine, and Racine. Firmin designed the Didot typeface. He also invented stereotypes (plates cast from printing surfaces) and was thus able to publish low-priced editions of French, Italian, and English books. Napoleon appointed him director of the imperial foundry, a position he held until his death.

François Didot's younger son, Pierre-François (c. 1731–93), was a typefounder, publisher, and papermaker. His three sons also joined the family businesses: Henri (1765–1852) is remembered for his microscopic types. For producing type he invented the Polymatype, which consisted of a long bar of matrices into which hot metal was poured. As many as 200 pieces of type could be cast in one operation. Léger (1767–1829) invented a papermaking machine, and the third son, called Didot *le jeune*, followed Henri as a typemaker.

Firmin Didot's sons, Ambroise-Firmin (1790–1876) and Hyacinthe-Firmin (1794–1880), took over his business when he retired. Their most important publishing venture was an edition of the *Thesaurus graecae linguae* compiled by Henri Estienne (9 vol., 1855–59). Among the many other important works they published were the 200 volumes comprising the *Bibliothèque des auteurs grecs*, *Bibliothèque latine*, and *Bibliothèque française*.

Didrikson, Babe: see Zaharias, Babe Didrikson.

Didyma, also called DIDYMI, or BRANCHIDAE, ancient sanctuary and seat of an oracle of Apollo, located south of Miletus in modern Turkey. Before being plundered and burned by the Persians (c. 494 BC), the sanctuary was in the charge of the Branchids, a priestly caste named after Branchus, a favourite youth of Apollo. After Alexander the Great conquered Miletus (334), the oracle was resanctified; the city administered the cult, annually electing a prophet. About 300 BC the Milesians began to build a new temple, intended to be the largest in the Greek world. The annual festival held there, the Didymeia, became Panhellenic in the beginning of the 2nd century BC. Excavations made between 1905 and 1930 revealed all of the uncompleted new temple and some carved pieces of the earlier temple and statues.

Didyme Insula (Italy): see Salina Island.

Didymelales, order of dicotyledonous flowering plants comprising the family Didymelaceae, with one genus (*Didymeles*) and two species, both of which are trees of Madagascar with very simple, primitive flowers. The plants are so distinctive that close relatives are nonexistent, as is reflected in the ordinal status given the group. The flowers are separately male and female, on different plants. The male flower consists of two anthers (pollen sacs) without stalks plus one or two small scales attached just below the anthers. The female flower consists of as many as four scales plus a single cylindrical carpel (ovule-bearing structure) with a large, obliquely situated pollen-receptive surface (stigma) and a single ovule.

The fruit is a drupe, large, one-seeded, fleshy, and plumlike, with a lateral groove. In addition to the primitive flowers, the wood also exhibits many primitive features—among others, water-conducting cells with ladderlike sculpturings on the walls (scalariform pitting); and sclereids (fibre cells) with large, distinctly bordered pits in the wall.

Didymograptus, genus of graptolites (an extinct group of colonial animals related to primitive chordates) found as fossils in Early

Didymograptus

and Middle Ordovician marine rocks (the Ordovician Period occurred from 505 to 478 million years ago). The several described species of *Didymograptus*, with their wide geographic distribution and relatively narrow time ranges, are guide fossils for correlation of Early and Middle Ordovician rocks and time. The genus is characterized by its two-branched form, frequently suspended from a circular disk-shaped structure. *Didymograptus* includes some of the largest known graptolites.

Didymus CHALCENTERUS (fl. c. 80–10 BC, Alexandria), Greek scholar and grammarian, one of the chief links between ancient and modern classical scholarship. His industry, as the reputed author of 3,500 books, earned him the nickname of Chalcenterus ("Brass Guts"). His output included work on the text of Homer, exegetical commentaries on numerous Greek authors, lexicographical compilations, and grammatical and antiquarian treatises.

Didymus THE BLIND (b. c. 313, Alexandria, Egypt—d. c. 398, Alexandria), Eastern church theologian who headed the influential catechetical school of Alexandria.

According to Palladius, the 5th-century bishop and historian, Didymus, despite having been blind since childhood and remaining a layman all his life, became one of the most learned ascetics of his time. Among those holding him in great esteem were Athanasius the Great, bishop of Alexandria, who made him head of the Alexandrian school, and Jerome, who acknowledged Didymus as his master. Jerome later retracted, however, when the works of Didymus, but not his person, were condemned by the Second Council of Constantinople (553) for teaching the doctrine of Origen (q.v.). Because of this condemnation, most of his works were not copied during the European Middle Ages and thus were lost. He was a leading opponent of Arianism (the Christian heresy that Christ is not truly divine but a created being).

Didymus' biblical commentaries (supposedly on nearly all the books of the Bible) survive in fragments only, and those on the Catholic Letters are of dubious authenticity. He is probably the author of a treatise on the Holy Spirit that is extant in Latin translation.

die, tool or device for imparting a desired shape, form, or finish to a material. Examples include a perforated block through which metal or plastic is drawn or extruded, the hardened steel forms for producing the patterns on coins and medals by pressure, and the hollow molds into which metal or plastic is forced. See also diesinking.

die-casting, forming metal objects by injecting molten metal under pressure into dies, or molds. An early and important use of the technique was in the Mergenthaler Linotype machine (1884) to give line-long combinations of letters, but the appearance of the mass-production automobile assembly line gave die-casting its real impetus. Great precision is possible, and products range from tiny parts for sewing machines and automobile carburetors to aluminum engine-block castings.

The two major die-casting techniques differ only in how the molten metal is introduced: in

the cold-chamber process, the metal is ladled into a chamber; a plunger impels the metal into the cold die cavity, in which it quickly hardens.

In the piston, or gooseneck, process the plunger and its cylinder are submerged in the molten metal, the metal being admitted through a hole in the top of the cylinder when the plunger is retracted; the advance of the plunger forces the metal into the die cavity as before. The die core is in position in the

Cold-chamber die-casting machine

From McGraw-Hill Encyclopedia of Science and Technology, vol. II, p. 30, copyright 1987, used with permission of McGraw-Hill Book Co

die cavity when the metal enters and fills the space around it; as soon as the metal hardens, the die core is retracted. The die is then opened, and the finished casting is ejected.

In modern die-casting the sequence is governed electronically.

dieback, common symptom or name of disease, especially of woody plants, characterized by progressive death of twigs, branches, shoots, or roots, starting at the tips. Staghead is a slow dieback of the upper branches of a tree; the dead, leafless limbs superficially resemble a stag's head. Dieback and staghead are caused by many fungi and a few bacteria that produce cankers, anthracnose, wilts, and stem or root rots. Nematodes, stem- or root-boring insects, mechanical damage, paving over roots, winter injury from cold or deicing salts, and a deficiency or excess of moisture

A pine tree afflicted with staghead dieback
Ingmar Holmasen

or an essential element may cause dieback, directly or indirectly.

Diebitsch, Johann (Karl Friedrich Anton), Graf (Count), Russian IVAN IVANOVICH DIBICH-ZABALKANSKY (b. May 13, 1785, Grossleipe, Silesia, Prussia—d. June 10, 1831,

Kleczewo, near Pultusk, Pol.), military officer whose Balkan campaigns determined the Russian victory in the Russo-Turkish War of 1828–29.

Although he was of German parentage and was educated at the Berlin cadet school, Diebitsch joined the Russian Army in 1801, and, after fighting against Napoleon in the battles of Austerlitz, Eylau, Friedland, and Smolensk, he acquired the rank of major general. He continued to serve in various military and diplomatic capacities as the Russians continued the war in western Europe (1812–14). In 1815 he attended the Congress of Vienna, at which the allies, having defeated Napoleon, reorganized Europe. Subsequently, Diebitsch became adjutant general to the Russian emperor Alexander I, chief of the Russian general staff (1824), a participant in the suppression of the Decembrist uprising, and a member of a secret committee formed by the emperor Nicholas I to examine administrative and social reform programs (1826–32).

After the Russo-Turkish War broke out (1828) and Diebitsch was given command of the Russian forces in Europe (February 1829), he defeated the Turks at Silistra on the Danube River, at the Kamchik River near Varna, and at Burgas (all in Bulgaria). Continuing his campaign, he advanced westward, inflicting another defeat upon the Turks at Sliven; he then turned south, forcing Adrianople (Edirne) to surrender and precipitating the conclusion of the Treaty of Edirne (Sept. 14, 1829), by which Turkey ceded the mouth of the Danube River and some territory in the Caucasus to Russia. For his victory Diebitsch was promoted to the rank of field marshal and given the name Zabalkansky to commemorate his march across the Balkans.

When the Poles staged an uprising against their Russian rulers (1830), Diebitsch led the Russian army that defeated the Poles at Grochów (Feb. 25, 1831) and at Ostroleka (May 20, 1831), but he died from cholera before the Poles capitulated.

Diefenbaker, John G(eorge) (b. Sept. 18, 1895, Grey County, Ont., Can.—d. Aug. 16, 1979, Ottawa), leader of the Progressive Conservative Party who was prime minister of Canada in 1957–63, following 22 years of uninterrupted Liberal rule.

Diefenbaker
National Film Board of Canada Phototheque

After serving in World War I, Diefenbaker practiced law in Saskatchewan. He was made king's counsel in 1929. In 1936 he was chosen as leader of the Saskatchewan Conservative Party, serving at that post until 1940, when he was elected to the Canadian House of Commons for the constituency of Lake Centre. His quest for leadership of the Progressive Conservative Party in 1948 was unsuccessful, but he became party leader in 1956.

The general election of 1957 brought victory for the Conservatives, breaking the 22-year Liberal monopoly, and Diefenbaker succeeded Louis Saint Laurent as prime minister. In the 1958 election the Conservatives won an unprecedented 208 of the 265 House seats. In the next election, however, in 1962,

the Conservatives lost their majority. A crisis over the proposed manufacture of nuclear weapons in Canada caused several ministerial resignations and forced Diefenbaker to call an election in 1963, when Lester B. Pearson, leading the Liberals, became prime minister. After struggling to retain party leadership, Diefenbaker resigned as party leader in 1967 and was succeeded by Robert Stanfield. Diefenbaker became chancellor of the University of Saskatchewan in 1969, at which post he served until his death.

Diego Garcia, coral atoll, largest and southernmost member of the Chagos Archipelago, in the southern Indian Ocean. Occupying an area of about 10.5 sq mi (27 sq km), it consists of a V-shaped, sand-fringed cay, about 15 mi (24 km) long with a maximum width of about 7 mi; the lagoon is open at the north end.

Discovered by the Portuguese in the early 16th century, it was for most of its history a dependency of Mauritius. In 1965 it was separated from Mauritius as part of the newly created British Indian Ocean Territory. The production of copra from coconut palms was the only economic activity until the early 1970s, when the last of the plantation workers and their families were moved to Mauritius to facilitate the development of U.S. military communications facilities established in accordance with a 1966 agreement between the United States and the United Kingdom. Development of this base for air and naval support in the late 1970s and '80s evoked strong opposition from littoral states of the Indian Ocean area, who wished to preserve a nonmilitarized status in the region.

During the First Persian Gulf War (1990–91), U.S.-led strikes on Afghanistan (2001), and the Second Persian Gulf War (2003), numerous air operations were launched from Diego Garcia.

In the late 1990s, islanders from the Chagos Archipelago, including Diego Garcia, sued for the right to return home, and in 2000 a British court ruled that the 1971 ordinance banning them from the islands was unlawful. U.S. and British officials, however, continued to fight attempts for resettlement, and a British court rejected the islanders' lawsuit in 2003.

Diegueño, also called SAN DIEGUEÑO, a group of Yuman-speaking Indians who originally inhabited large areas extending on both sides of what is now the U.S.–Mexican border in California and Baja California. They were named after the mission of San Diego.

Diegueño culture reflected similarities with its neighbours the Luiseño to the north and other Yuman nations to the east, such as the Mojave (see Yuman Indians). Diegueño social organization was based upon lineage, each apparently associated with a particular location. The lineage chief led ceremonies. The diet staples of coastal Diegueño were fish and mollusks. Inland, some Diegueño engaged in agriculture. Their houses consisted of poles supporting a roof of brush and earth. They made baskets, pottery, and containers made of string substances.

Although many Diegueño religious practices paralleled those of the Luiseño, the world views of the two differed. Whereas the Luiseño were mystics, the Diegueño were more interested in the solid and visible in life.

Like most other California Indians with missions placed in their midst, the Diegueño resisted the Christianizing efforts of the Spanish Franciscans; they even attacked the San Diego mission. Conversions were not extensive.

In the early 21st century about 2,000 Diegueño descendants lived in California.

Dielasma, genus of extinct brachiopods, or lamp shells, that occur as fossils in rocks deposited in marine environments of Mississippian to Permian age (between 225,000,000 and 345,000,000 years old). The two small,

rather smooth valves of the shell of *Dielasma* are slightly convex in profile, but the pedicle, or foot, valve is much larger than the brachial, or upper, valve. Growth lines are generally apparent. In some respects *Dielasma* is similar to

Dielasma

Composita, a brachiopod with similar time range and habitat.

dieldrin, chlorine-containing organic compound used as an insecticide; see aldrin.

dielectric, insulating material or a very poor conductor of electric current. When dielectrics are placed in an electric field, practically no current flows in them because, unlike metals, they have no loosely bound, or free, electrons that may drift through the material. Instead, electric polarization occurs. The positive charges within the dielectric are displaced minutely in the direction of the electric field, and the negative charges are displaced minutely in the direction opposite to the electric field. This slight separation of charge, or polarization, reduces the electric field within the dielectric.

The presence of dielectric material affects other electrical phenomena. The force between two electric charges in a dielectric medium is less than it would be in a vacuum, while the quantity of energy stored in an electric field per unit volume of a dielectric medium is greater. The capacitance of a capacitor filled with a dielectric is greater than it would be in a vacuum. The effects of the dielectric on electrical phenomena are described on a large, or macroscopic scale by employing such concepts as dielectric constant, permittivity ($qq.v.$), and polarization (see polarization, electric).

dielectric constant, property of an electrical insulating material (a dielectric) equal to the ratio of the capacitance of a capacitor filled with the given material to the capacitance of an identical capacitor in a vacuum without the dielectric material. The insertion of a dielectric between the plates of, say, a parallel-plate capacitor always increases its capacitance, or ability to store opposite charges on each plate, compared with this ability when the plates are separated by a vacuum. If C is the value of the capacitance of a capacitor filled with a given dielectric and C_0 is the capacitance of an identical capacitor in a vacuum, the dielectric constant, symbolized by the Greek letter kappa, κ , is simply expressed as $\kappa = C/C_0$. Dielectric constant is a number without dimensions. It denotes a large-scale property of dielectrics without specifying the electrical behaviour on the atomic scale.

The value of the static dielectric constant of any material is always greater than one, its value for a vacuum. The value of the dielectric constant at room temperature (25° C, or 77° F) is 1.00059 for air, 2.25 for paraffin, 78.2 for water, and about 2,000 for barium titanate ($BaTiO_3$) when the electric field is applied perpendicularly to the principal axis of the crystal. Because the value of the dielectric

constant for air is nearly the same as that for a vacuum, for all practical purposes air does not increase the capacitance of a capacitor. Dielectric constants of liquids and solids may be determined by comparing the value of the capacitance when the dielectric is in place to its value when the capacitor is filled with air.

The dielectric constant is sometimes called relative permittivity or specific inductive capacity. In the centimetre-gram-second system the dielectric constant is identical to the permittivity (*q.v.*).

dielectric heating, also called CAPACITANCE HEATING, method by which the temperature of an electrically nonconducting (insulating) material can be raised by subjecting the material to a high-frequency electromagnetic field. The method is widely employed industrially for heating thermosetting glues, for drying lumber and other fibrous materials, for preheating plastics before molding, and for fast jelling and drying of foam rubber.

The material to be heated is placed between two metal plates, called electrodes, to which a source of high-frequency energy is connected. The resultant heating, in homogeneous materials, occurs throughout the material.

Diels, Otto Paul Hermann (b. Jan. 23, 1876, Hamburg—d. March 7, 1954, Kiel, W.Ger.), German organic chemist who with Kurt Alder was awarded the Nobel Prize for Chemistry in 1950 for their joint work in developing a method of preparing cyclic organic compounds.

He studied chemistry at the University of Berlin under Emil Fischer and after various appointments was made professor of chemistry at the University of Kiel (1916). He became emeritus in 1945.

In 1906 he discovered a highly reactive substance, carbon suboxide (malonic anhydride), and determined its properties and chemical composition. He also devised an easily controlled method of removing some of the hydrogen atoms from certain organic molecules by the use of metallic selenium.

His most important work concerned the diene synthesis, in which organic compounds with two carbon-to-carbon double bonds were used to effect syntheses of many cyclic organic substances under conditions that threw light on the molecular structure of the products obtained. This method was developed (1928) in collaboration with Kurt Alder, his student, and is known as the Diels-Alder reaction. Their work proved especially important in the production of synthetic rubber and plastics.

Diem, Ngo Dinh: see Ngo Dinh Diem.

Diemen, Anthony van (b. 1593, Culemborg, Neth.—d. April 19, 1645, Batavia, Dutch East Indies), colonial administrator who as governor general of the Dutch East Indian settlements (1636–45) consolidated the Dutch empire in the Far East.

After an unsuccessful business career in Amsterdam, van Diemen joined the Dutch East India Company, serving in Batavia from 1618 and becoming governor general in 1636. To strengthen the company's rule in the Moluccas, he signed a treaty with the Sultan of Ternate in 1638, which freed the Company for a war of conquest (1638–43) and resulted in a Dutch spice monopoly in the area. Also in 1638 van Diemen intensified the Dutch attack on the Portuguese empire in Asia with an invasion of Ceylon. By 1644 the Dutch had conquered Ceylon's cinnamon-producing areas and had established posts on India's Coromandel Coast.

Meanwhile van Diemen had succeeded in seizing the key Portuguese stronghold of Malacca (1641; now in Malaysia) on the trade route between India and China, and in 1642

the Dutch captured all of Formosa (Taiwan), driving out the Spaniards. Under his rule, advantageous treaties with the East Indian princes of Acheh (Atjeh) and Tidore were signed, and commercial relations with Tonkin (Vietnam) and Japan were established. By the end of van Diemen's administration, the United Provinces of the Netherlands had become the paramount commercial and political power in the East Indies.

Van Diemen completed the construction of Batavia in the Dutch pattern of his predecessor, Jan Pieterszoon Coen, including a Latin school, Protestant churches, an orphanage, and a hospital; he also introduced a legal code known as the Batavian statutes. Van Diemen initiated the exploring expeditions of Abel Tasman and Frans Visser in 1642 and 1644 on which they discovered Tasmania (originally Van Diemen's Land), New Zealand, Tonga, Fiji, and the northern coast of Australia.

Diémer, Louis-Joseph (b. Feb. 14, 1843, Paris—d. Dec. 21, 1919, Paris), French pianist and teacher who was one of the first advocates of early keyboard music and instruments.

He was a student at the Paris Conservatoire from 1856 to 1861, and from 1863 he performed regularly, playing at the Alard, Padeloup, Colonne, Lamoureux, and Conservatoire concerts with great success; his repertoire included pieces written for him by Charles-Marie Widor, Camille Saint-Saëns, and Édouard Lalo. He was appointed professor of piano at the Conservatoire in 1887; in 1889 he gave a series of harpsichord recitals there whose favourable reception encouraged him to establish a Société des anciens instruments. He edited a collection of early French keyboard pieces (*Clavecinistes français*, 1928). Active also as a composer, he wrote both piano and orchestral works. Among his students were Alfred Cortot and Robert Casadesu.

Dien Bien Phu, Battle of, the decisive engagement in the first Indochina War (1946–54). It consisted of a struggle between French and Viet Minh (Vietnamese Communist and nationalist) forces for control of a small mountain outpost on the Vietnamese border near Laos. The Viet Minh victory in this battle effectively ended the eight-year-old war.

The battle was joined in late 1953 when French forces, who had been rapidly losing ground to the popularly supported Viet Minh, occupied the town of Dien Bien Phu in an attempt to cut the nationalist supply lines into Laos and to maintain a base for forays against enemy forces. Although the Vietnamese quickly cut all the roads into Dien Bien Phu, making it suppliable only by air, the French were confident of their position. They were then taken by surprise when the Viet Minh Gen. Vo Nguyen Giap surrounded the base with 40,000 men and used heavy artillery to break the French lines. Despite heavy U.S. aid, the base was overrun on May 7, 1954.

With French forces in disarray after the battle, the French government sought an end to the fighting; an official settlement was negotiated at an international conference in Geneva. The French sense of national humiliation, particularly acute within the army, had lasting repercussions on French public opinion and contributed—along with later events in Algeria—to the downfall of the Fourth Republic in 1958.

Dienerian Stage, division of Triassic rocks and time (the Triassic Period began about 225,000,000 years ago and lasted about 35,000,000 years). Dienerian rocks, deposited in a marine environment, overlie those of the Griesbachian Stage and underlie rocks of the Smithian Stage. These stages, together with the Spathian Stage, comprise the Lower Triassic Series. Dienerian rocks are characterized by a distinctive fossil cephalopod fauna

and have been correlated with rocks throughout the world, although regional names may sometimes be employed.

Dienné (Mali): see Djénné.

Dientzenhofer, Christoph and Kilian Ignaz (respectively b. July 7, 1655, Rosenheim, Bavaria—d. June 20, 1722, Prague; b. Sept. 1, 1689, Prague—d. Dec. 18, 1751, Prague), father and son, members of a large family of German architects, who were among the leading builders in Bohemian Baroque. Among their joint works are the Church of St. Nicholas (1703–11, 1732–52) and the Břevnov Monastery (1708–21), both in Prague. K.I. Dientzenhofer built the churches of St. Thomas (1725–31; a Gothic structure reworked into Baroque) and St. John on the Rock (1730–39; including the Vyšehrad Steps),

Church of St. Nicholas in the Old City, Prague, by Christoph and Kilian Ignaz Dientzenhofer, 1703–11, 1732–52

Helga Schmidt-Glassner

both in Prague, and St. Mary Magdalene, Karlsbad (now Karlovy Vary; 1733–36); he also built the Villa Amerika (1712–20; afterward the Antonín Dvořák Museum), Prague.

Dieppe, town and seaport, northern France, Seine-Maritime *département*, Haute-Normandie region, on the English Channel, north of Rouen and northwest of Paris. It stands at the mouth of the Arques River in a valley bordered on each side by steep white cliffs.

In the old town many houses date back to the early 18th century. The castle, built in 1435, was damaged in 1944 but has been restored and now houses a museum. Much of the town was rebuilt after World War II. Dieppe is the seaside resort closest to Paris; the pebbly beach with its marine promenade became fashionable in the 19th century. A casino is nearby.

The name Dieppe probably comes from the Saxon word *deop* ("deep")—a reference to the depth of the estuary. The French kings, realizing the strategic importance of the town, granted it numerous privileges; when it was occupied by the English during the Hundred Years' War, the inhabitants expelled them at the first opportunity, in 1435. Dieppe, mainly Protestant, suffered greatly during the Wars of Religion, but its darkest period came in the second part of the 17th century. In 1668 almost 10,000 of its people died during a plague; in 1685 the Protestants of the town were persecuted after the revocation of the Edict of Nantes; and in 1694 the town was

almost completely destroyed by the English and Dutch fleets. The Allies landed in Dieppe in August 1942 and suffered serious losses in a test of German defenses near port facilities.

The port, cut in the bed of the Arques River, is one of the safest on the English Channel, but its shallowness hinders modern shipping. The passenger harbour has a regular service with Newhaven, Eng., except in winter. The fishing harbour is one of the main suppliers of the Paris market, and there is a well-equipped commercial port. The main industries include shipbuilding, oil refining, and the manufacture of rope, textiles, and (since the 15th century) articles in bone and ivory. More recent industries include telephone equipment, clocks and watches, chemicals, and automobiles. Pop. (1982) 35,659.

Dies, Martin, Jr. (b. Nov. 5, 1901, Colorado, Texas, U.S.—d. Nov. 14, 1972, Lufkin, Texas), American politician, the sponsor and first chairman (1938–45) of the House Committee on Un-American Activities.

A graduate of the University of Texas (1919) and the law school of National University in Washington, D.C. (1920), Dies opened a law practice in Texas but quickly turned his attention to politics. In 1931 he won a seat in the U.S. House of Representatives, where, following the election of Franklin Roosevelt, he supported the New Deal. By 1937, however, he had turned against Roosevelt and the liberal wing of the Democratic Party.

In 1938, after several unsuccessful attempts, Dies convinced the House to establish the Committee to Investigate Un-American Activities (later renamed the Committee on Un-American Activities, but always more popularly called the Dies Committee). As chairman, Dies rigorously pursued alleged subversives in New Deal agencies, labour unions, and other organizations. Although the committee was supposed to investigate fascist subversion as well, it quickly turned exclusively to supposed communist infiltration of American life.

As a result of the committee's well-publicized investigations, Dies gained a national reputation. Conservative groups applauded his zeal in exposing left-wing subversives, while liberals denounced his tactics of smearing reputations with unproven allegations. In his 1940 book, *The Trojan Horse of America*, Dies claimed to have surpassed the FBI in uncovering communist subversives in America.

Dies resigned his congressional seat in 1945 to resume his Texas law practice. But he returned to the House in 1953 and served until 1959, though he held no important positions during those years. After retiring once again from public life, he spent his final years in Texas practicing law.

Dies irae (Latin: "Day of Wrath"), the opening words of a Latin hymn on the Last Judgment, ascribed to Thomas of Celano (d. c. 1256) and forming part of the office for the dead and requiem mass.

The hymn ascribed to Thomas of Celano contains 18 rhymed stanzas (17 tercets, 1 quatrain), to which a later, anonymous writer added an unrhymed couplet, ending in "Amen." The impressive plainsong melody to which the hymn was sung was used by composers of religious works from the 16th century onward, either in its original form or as the basis of a polyphonic composition. Wolfgang Amadeus Mozart and Giuseppe Verdi were among the composers of religious works who wrote original music on the text of the hymn.

The original melody made a strong appeal during the Romantic period and was used, often in the form of a parody or to suggest the supernatural or the macabre, in many secular compositions by Hector Berlioz, Camille Saint-Saëns, Ralph Vaughan Williams, and other composers.

Diesel, Rudolf (Christian Karl) (b. March 18, 1858, Paris—d. Sept. 29, 1913, at sea in the English Channel), German thermal engineer who invented the internal-combustion engine that bears his name. He was also a distinguished connoisseur of the arts, a linguist, and a social theorist.

Diesel, the son of German-born parents, grew up in Paris until the family was deported to England in 1870 following the outbreak of the Franco-German War. From London Diesel was sent to Augsburg, his father's native town, to continue his schooling. There and later at the Technische Hochschule (Technical High School) in Munich he established a brilliant scholastic record in fields of engineering. At Munich he was a protégé of the refrigeration engineer Carl von Linde, whose Paris firm he joined in 1880.

Diesel devoted much of his time to the self-imposed task of developing an internal combustion engine that would approach the theoretical efficiency of the Carnot cycle. For a time he experimented with an expansion engine using ammonia. About 1890, in which year he moved to a new post with the Linde firm in Berlin, he conceived the idea for the diesel engine (*q.v.*). He obtained a German development patent in 1892 and the

Diesel, 1883

By courtesy of the Deutsches Museum, Munich

following year published a description of his engine under the title *Theorie und Konstruktion eines rationellen Wärmemotors (Theory and Construction of a Rational Heat Motor)*. With support from the Maschinenfabrik Augsburg and the Krupp firms, he produced a series of increasingly successful models, culminating in his demonstration in 1897 of a 25-horsepower, four-stroke, single vertical cylinder compression engine. The high efficiency of Diesel's engine, together with its comparative simplicity of design, made it an immediate commercial success, and royalty fees brought great wealth to its inventor.

Diesel apparently fell from the deck of the mail steamer *Dresden* en route to London and drowned.

diesel engine, any internal-combustion engine in which air is compressed to a temperature sufficiently high to ignite fuel injected into the cylinder where combustion and expansion actuate a piston. It converts the chemical energy stored in the fuel into mechanical energy, which can be used to power freight trucks, large tractors, locomotives, and vessels. A limited number of automobiles also are diesel-powered, as are small electric-power generators.

A brief treatment of diesel engines follows. For full treatment, see MACROPAEDIA: Energy Conversion.

The diesel engine differs from other internal-combustion engines such as gasoline engines that induct and moderately compress an inflammable mixture of air and vaporized or gaseous fuel and then ignite it by an electric spark. It employs no ignition devices, and so is often called a compression-ignition engine. The possibility of compression ignition

appears to have been first mentioned by the French physicist Sadi Carnot in 1824. The principle on which the modern automobile engine operates was conceived in 1862 by Alphonse Beau de Rochas, also of France; however, it was not applied to a practical engine until 1876, when the German engineer Nikolaus Otto built the first engine in which the charge (fuel-air mixture) was compressed in the cylinder before burning. This was the engine that Rudolf Diesel, a German engineer, undertook to improve when he started the experiments that led to the diesel engine.

After several years of studying the problems involved, Diesel applied for and was granted patents in 1892 and 1893. The processes described in these patents represented a cycle that differed from the theoretical or ideal cycle followed by existing engines only in the rate of combustion of the fuel-air charge. He proposed to burn the fuel during the first portion of the power stroke of the piston so slowly that no pressure rise would occur. As a means of slowing down combustion to avoid the almost instantaneous explosion of the spark-ignition engine, he suggested inducting air into the cylinder and compressing it so highly that it would attain a temperature above the ignition point of an appropriate fuel, which would be gradually sprayed into the combustion chamber during the descent of the piston. This method of igniting fuel requires that the air be compressed to a pressure of at least 3,450 kilopascals (500 pounds per square inch), which produces a temperature of approximately 540° C (1,000° F).

Diesel presumably thought that any fuel would be suitable for an engine operating in the manner he described. He attempted to build an engine that would burn powdered coal, the cheapest conceivable fuel. The coal-burning project, however, was soon abandoned, and an oil-burning version of the engine was completed in 1897.

The fuel economy of Diesel's engine proved to be better than that of any other existing power plant. The engine, however, was not rapidly adopted. Until his death in 1913, Diesel insisted that all engines manufactured under his license be made to operate with combustion at practically constant pressure, as described in his 1893 patent. This restriction meant that the engines had to run at a very low speed, and thus possible design improvements were delayed. The early diesel engines were so large and heavy in proportion to their power output that they had no application other than as stationary power plants.

The first marine installation of a diesel engine was completed in 1910; the diesel engine became the primary power plant for submarines during World War I. The first diesel engine that was small and light enough for use in automobiles was built in 1922 in Germany, and it opened up numerous fields of application that had previously been closed to diesel engines because of their low specific power output. The higher-speed diesel engines do not follow the slow-burning cycle originated by Diesel. Fuel is injected into the cylinder near the end of the compression stroke and burned rapidly, with sharply rising pressure, while the piston is near its dead-centre position. Only the compression-ignition and fuel injection of Diesel's original engine are retained in the modern high-speed version.

Since the mid-1940s the diesel engine has become the predominant source of industrial power throughout the world for units up to roughly 5,000 horsepower, principally because it is capable of burning a low-grade fuel at a comparatively low rate of consumption per horsepower per hour. Relatively unrefined fuels can be burned by a diesel engine because of the nature of its fuel-injection system and

combustion process. Low fuel consumption results primarily from the higher compression ratio used. A greater fuel saving is effected at partial load than at full load since it is not necessary to throttle the inlet air, as in the case with spark ignition, to maintain an inflammable fuel-air mixture. (Only about two-thirds as much fuel is required.) Diesel engines do have some disadvantages, however. They are, for example, handicapped somewhat by their higher initial cost and greater weight per horsepower, by their emission of high levels of air pollutants (e.g., nitric oxide and soot) and odour, and by their greater operating noise and vibration.

diesinking, process of machining a cavity in a steel block to be used for molding plastics, or for hot and cold forging, die-casting, and coining.

The die block is mounted on a table while a vertical-spindle milling machine with end cutters is used to shape the die. In most simple machines the movement of the cutter may be controlled by the manual operation of transverse, horizontal, and vertical feeds. Patterns of sheet metal or plastic may be used as guides. A pantograph (*q.v.*), four light rigid bars in a parallelogram, may be used to cause the cutter to follow a certain layout.

Diesinking on the Milwaukee rotary head, vertical milling machine

By courtesy of the Kearney and Trecker Corp

Diesinking is done chiefly by automatic machines. The movement of the cutter against the die block is controlled by tracing a finger gauge the size and shape of the cutter in contact with a previously made model of soft metal, plaster of paris, or wood. The model, or template, is attached to the bed beside the die block. The movement of the finger over the template is transmitted to the cutter by hydraulic or electrical controls. The surface of the sunken die is finished to the desired size and surface quality by hand scrapers, files, small grinding wheels, and polishing cloth.

Diespiter (Roman god): *see* Jupiter.

Diet, Medieval Latin *DIETA*, German *REICHSTAG*, legislature of the German empire, or Holy Roman Empire, from the 12th century to 1806.

In the Carolingian empire, meetings of the nobility and higher clergy were held during the royal progresses, or court journeys, as occasion arose, to make decisions affecting the good of the state. After 1100, definitively, the emperor called the Diet to meet in an imperial or episcopal city within the imperial frontiers. The members of the Diet were originally the princes, including bishops of princely status, but counts and barons were included later. After 1250 the representatives of imperial and episcopal cities were recognized as members of the Diet, and at this time the electoral princes,

whose duty it was to elect the emperor, began to meet separately, a division formally confirmed in the Golden Bull of Charles IV (1356), which established the number of the electoral princes as seven. (*See* elector.)

Beginning in the 12th century the power of the emperor gradually declined; by 1489 the Diet was divided into three colleges that met separately: (1) the electoral college of seven lay and ecclesiastical princes presided over by the imperial chancellor, the archbishop of Mainz; (2) the college of the princes with 33 ecclesiastical princes and 61 lay princes, presided over by the archbishop of Salzburg or the archduke of Austria; (3) the college of the cities presided over by the representative of the city in which the Diet met. The college of cities was separated eventually into the Rhine and Swabian divisions, the former having 14 towns and the latter 37.

The decisions taken separately by the three colleges were combined in an agreed statement the text of which was sent to the emperor as "the resolution of the empire" (*conclusum imperii*). All the decisions of the Diet forming the resolution were called the "recess of the empire" (*Reichsabschied*). The emperor could ratify part of the recess or the whole of it, but he could not modify the words of the recess. Until the 17th century the Diet possessed effective legal power, including the decision of war or peace, but the Peace of Westphalia (1648) spelled the final breakdown in the conception of a single German empire united by its members' common aims. The three-college Diet was replaced by an assembly of sovereign princes, usually represented by envoys, indifferent to the emperor's wishes and divided in religious and political aims. The Diet of Regensburg of 1663 prolonged itself indefinitely into permanent session and thereafter was called the Regensburg Diet, or the Everlasting Diet (*Immerwährender Reichstag*). The emperor was now represented by a prince of the empire as his commissioner; a jurist was appointed as subcommissioner; and the elector of Mainz, archchancellor of the empire, had charge of the business of the meetings of the Diet. This assembly of representatives without legislative power disappeared when the Holy Roman Empire collapsed under Napoleon's attack in 1806.

The name Reichstag was revived in 1871 for the legislature of the German Empire and retained by the Weimar Republic and the Third Reich; the name was abandoned in the two Germanies after World War II.

Diet, also called (1889–1947) **IMPERIAL DIET**, Japanese *KOKKAI* ("National Assembly"), or *TEIKOKU GIKAI* ("Imperial Assembly"), the national legislature of Japan.

Under the Meiji Constitution of 1889, the Imperial Diet was established on the basis of two houses with coequal powers. The upper house, the House of Peers (*Kizokuin*), was almost wholly appointive. Initially, its membership was slightly less than 300, but it was subsequently increased to approximately 400. The peers were intended to represent the top rank and quality of the nation and to serve as a check upon the lower house. The pre-World War II House of Representatives (*Shūgiin*) was originally composed of 300 members, all elected, but gradually this number was increased to 466. Its powers were in many respects largely negative. Without Diet approval, no bill could become law. The government did have the right to issue imperial ordinances in case of an emergency, but if these were to remain in effect the Diet had to approve them at its next session. There was one significant limitation upon the traditional legislative control over the purse strings. If the Diet did not pass the budget in a manner acceptable to the government, the government had the right to apply the budget for the previous year. This provision was borrowed from Prussian

practice. The Diet did not initiate important legislation; this was chiefly the function of the executive.

Under the Constitution of 1947 the Diet, renamed *Kokkai*, was drastically altered both in structure and in powers. There remained two houses, the House of Representatives (*Shūgiin*) and the House of Councillors (*Sangiin*). The latter takes the place of the old House of Peers and has a membership of 250 consisting of two categories: 100 councillors elected from the nation at large with the remaining 152 elected as prefectural representatives. Every voter may cast a ballot for one candidate in each category, giving him a total of two votes. The members of the House of Councillors serve for six years, with one-half of the members standing for election every three years. The House of Councillors cannot be dissolved in case of conflict between it and the executive branch. The balance of power, though, lies in the lower house, where general agreement with executive policy must prevail. In case of a deadlock between the two houses over the selection of a prime minister, the vote of the lower house takes precedence. The budget must be submitted first to the lower house; if the two houses cannot agree, the position of the lower house prevails after 30 days. This same provision applies to treaties. With other legislation, if the councillors reject a bill or refuse to act upon it within 60 days, the House of Representatives can make it law by passing it by a two-thirds majority of the members present.

The House of Representatives has 467 members elected from 118 electoral districts. Each district has from three to five representatives, but the voter casts only one ballot, with the candidates receiving the highest number of votes being elected. Lower-house members are elected for a term of four years, but the house can be dissolved at any time by the government, in which case elections must be held within 40 days.

As in the past, the Japanese Diet rarely initiates important legislation; such laws ordinarily come to the Diet under cabinet sponsorship. However, an individual member's bill can be introduced in the lower house if it has been signed by 20 or more members, and in the upper house with the signature of 10 or more members. Under Diet law, the committee system has been drastically altered to accord more with U.S. practice. Each house has slightly more than 20 standing committees dealing with such subjects as foreign affairs, finance, and education. Government legislation goes first to the appropriate committee, where it is examined and often vigorously debated. Membership on these committees is determined by the Diet in rough accordance with the party ratios in each house. A member normally retains his assignments as long as he sits in the Diet. Thus he develops some detailed knowledge and may provide a challenge to government policymakers of opposing parties or convictions.

Japanese politics in the second half of the 20th century has revolved around the Diet. That body is no longer on the periphery as it was under the Meiji Constitution. Moreover, with all adults over 21 eligible to vote, the Diet is more representative of the public will than it has been at any time in the past. Certain historic problems remain, however. Large-scale scandals are not lacking; the basic causes of corruption have not been eliminated. Even provided with constitutional support, the Diet has had some difficulty establishing itself as a respected body in the eyes of many of the Japanese people. Slowly, however, democratic procedures have acquired a tradition and an acceptance in Japan.

diethyl ether: *see* ethyl ether.

diethylcarbamazine citrate, synthetic anthelmintic drug (worming agent) effective

against most of the parasitic filarial worms, which are endemic throughout most of the subtropical and tropical regions of the world. These parasites infect the blood and lymph channels in human beings, causing the debilitating disease filariasis (*g.v.*). Diethylcarbamazine citrate is effective in treating filariasis caused by *Wuchereria bancrofti* and *Brugia malayi* (which infect the lymphatic system, causing diseases such as elephantiasis) and *Loa loa* (which infects the subcutaneous tissues). The drug is administered orally.

diethylstilbestrol (DES), nonsteroidal synthetic estrogen used as a drug and formerly used to promote growth of livestock. Unlike natural estrogens, DES remains active following oral administration. It is also administered as vaginal suppositories and by injection. DES breaks down more slowly in the body than do the natural estrogens.

DES is used therapeutically to replace estrogen during menopause, to relieve painful menstrual periods (dysmenorrhea), to stimulate the development of secondary sexual characteristics in women with nonfunctioning ovaries, and to palliate advanced breast cancer in women and prostate cancer in men.

Beginning in the 1940s and continuing for more than 20 years, DES was frequently prescribed to pregnant women to prevent miscarriages. In 1971 investigators demonstrated statistically that daughters of women taking DES had abnormally high rates of an otherwise rare form of cervicovaginal cancer. The use of DES and other estrogens during pregnancy is now proscribed in many countries.

Until the 1970s it was common practice to stimulate the fattening of beef cattle and chickens by mixing small amounts of DES into the feed or by implanting pellets of DES under the skin in the ears of the animals. Concern over trace amounts of the hormone in meat led to bans on the use of DES as a livestock growth stimulant beginning in the early 1970s.

dieting, regulating one's food intake for the purpose of improving one's physical condition, especially for the purpose of reducing obesity, or what is conceived to be excess body fat. Dieting plans are based on the reduction of any of the macronutrients (fats, carbohydrates, and proteins) that constitute the major portions of food that a person eats (other than water) and that are necessary sources of energy. Energy deficits of 500–1,000 calories per day produce rather rapid initial weight loss owing to the early loss of body water, especially if carbohydrates are restricted. But, after the initial effects of dehydration, all the dieting plans produce a rate of fat loss that can only be proportional to the caloric deficit.

The following are some major approaches to dieting:

(1) Controlled dieting such as that directed by weight-control clubs (*e.g.*, Weight Watchers International, Inc.) and health spas involves programs that include education on nutrition, group reinforcement, specially constructed diets that provide adequate amounts of nutrients, and weight-maintenance regimens that are designed for long-term use. Although long-term success rates are difficult to determine, the dietary regimens are usually well-designed and can be counted on to provide proper nourishment even if weight loss is minimal.

(2) The so-called "prudent diet" is designed to control blood lipids and cholesterol for those persons at risk of coronary artery diseases. The prudent diet and its relatives stress a low-saturated and high-unsaturated fat content and limited amounts of sugar; they restrict red meat and stress poultry and nonoily fish.

(3) "Formula diets," such as Metrecal, Slender Now, and the Cambridge Diet plan, provide for the intake of a minimum of necessary nutrients—especially protein—in liquid form.

Many such plans are packaged with liquids or powdered supplements, to be consumed variously from one to four times a day; modified versions call for two liquid meals and one meal of conventional food. The advantages of such formulas are ritual and reduced decision making, and the disadvantages are that dieters learn nothing about eating habits because choices are made for them and, also, that the more restrictive of these diets (down to 300 calories per day) can be quite dangerous to the health. Restrictive plans should be undertaken with medical supervision.

(4) The low-carbohydrate, high-fat, and high-protein diets, which became rather popular from the early 1970s, restrict sugars and starches to a minimum by stressing meats, poultry, fish, and cheeses. The effect on the body is to produce ketosis and dehydration; thus initial weight loss may be marked. Although calories are not counted, the usual caloric intake is reduced because most human bodies are unable to adapt rapidly to the marked change in dietary composition. Weight is lost quickly but is returned as soon as normal eating habits are reestablished. The richness of the diet, in general, may produce dangerous effects related to the excretion of large amounts of uric acid and other nitrogenous end products and to the high saturated-fat content of the diet.

(5) High-carbohydrate, high-fibre diets promote the consumption of vegetables, fruits, nuts, and whole grains. Dietary fibre is a general term for indigestible carbohydrates that make up the cell walls of plants. Such fibres, as bulking agents, may make dieters feel satiated on food of fewer calories than normal. The best of the high-carbohydrate diets are moderate in protein and low in fat and promise slow weight loss with exercise and careful nutritional consideration. Some plans, however, are so low in calories or so low in protein or fat as to be nutritionally unsound.

(6) Fasting may consist of skipping a few meals or going a few days or weeks without food (other than water and, perhaps, vitamins and minerals). Fasting may serve the needs of those persons with just a few pounds to lose, but it is not effective for obese individuals or for anyone seeking long-term weight control. Fasting can be medically dangerous.

(7) Diet aids—such as amphetamines, phenylpropanolamine (PPA), starch blockers, benzocaine, diuretics, and thyroid hormones—come in pill form and are intended to suppress the appetite or reduce stomach space. Many such aids—such as amphetamines—have proved to be dangerous, whereas others are simply ineffective. Over-the-counter preparations such as PPA are ineffective in the dose provided (25 mg), though promotion for the product continues. The search continues for safe and effective appetite suppressants and for hormonal agents that may safely increase metabolic rate without inducing concomitant loss of lean body mass, including protein and bone.

Dietmar (historian): see Thietmar.

Dietrich, Marlene, original name MARIE MAGDALENE VON LOSCH (b. Dec. 27, 1901, Berlin, Ger.—d. May 6, 1992, Paris, Fr.), motion-picture actress whose aura of sophistication and languid sensuality made her one of the most glamorous of all film stars.

Born the daughter of a German police officer, she at first studied the violin and then studied acting under Max Reinhardt, the innovative theatrical director. She eventually joined Reinhardt's theatre company. Seven years after her first appearance in German films as an extra, her stardom was established by her role as Lola-Lola, a sultry and world-weary nightclub performer in Josef von Sternberg's *Der blaue Engel* (1930; *The Blue Angel*). Adapted from Heinrich Mann's novel *Professor Unrat*, the film was an international success. After

its premiere, von Sternberg brought her to the United States, where they collaborated on such pictures as *Morocco* (1930), *Dishonored* (1931), *Blonde Venus* (1932), *Shanghai Express* (1932), *The Scarlet Empress* (1934), and *The Devil Is a Woman* (1935). *Desire* (1936) and *Destry Rides Again* (1939) revealed her talent as a comedienne.

Marlene Dietrich
Pictorial Parade

From 1943 to 1946 Dietrich made more than 500 personal appearances before Allied troops. After World War II she continued to make successful films, such as *A Foreign Affair* (1948), *The Monte Carlo Story* (1956), *Witness for the Prosecution* (1957), *Touch of Evil* (1958), and *Judgment at Nuremberg* (1961). She was also a popular nightclub performer. In 1978, after a period of retirement from the screen, she appeared in the film *Just a Gigolo*. In 1986 there appeared the documentary film *Marlene*, a review of her life and career, with a voice-over interview of the star by Maximilian Schell. Her autobiography, *Ich bin, Gott sei Dank, Berliner* ("I Am, Thank God, a Berliner"; Eng. trans. *Marlene*) appeared in 1987.

Dietrich, Paul-Henri: see Holbach, Paul-Henri Dietrich, baron d'.

Dietrich von Bern, heroic figure of Germanic legend, apparently derived from Theodorich the Great, an Ostrogothic king of Italy who reigned 493–526.

Dietrich's exploits are related in a number of south German songs preserved in *Das Heldenbuch* ("The Heroes Book")—including *Dietrichs Flucht* ("Dietrich's Flight"), *Die Rabenschlacht* ("The Battle of Ravenna"), *Alpharts Tod* ("Alphart's Death"), and a number of additional stories—and, more fully, in the 13th-century Icelandic prose *Thidriks saga*. This legend also has a connection with the Middle High German epic *Nibelungenlied*. References to Dietrich in Anglo-Saxon records are few and obscure.

Driven by Ermanaric from his kingdom of Berne (Verona), Dietrich lives for many years at Attila's court, until he returns with a Hunnish army to defeat Ermanaric at the Battle of Ravenna (Rabenschlacht). Attila's two sons fall in the fight, and Dietrich returns to Attila to answer for their deaths. Later he has his revenge by slaying Ermanaric. Dietrich's long stay with Attila represents Theodorich's youth spent at the Byzantine court. The exile is adorned with amazing exploits, most of which have no connection with the cycle.

Dietrich typifies the wise and just ruler as opposed to the tyrannical Ermanaric. Many of the incidents told about him have no basis in the story of Theodorich, although some

could be related to the experiences of Theodor's father, Theudemir. The chief heroes of the Dietrich cycle are his weapons master, Hildebrand, with his nephews Alphart and Wolfhart; Wittich, Dietrich's traitorous vassal who slays Attila's sons; and Heime and Biterolf.

Dietz, Howard (b. Sept. 9, 1896, New York, N.Y., U.S.—d. July 30, 1983, New York City), American motion-picture executive and songwriter.

After graduating from Columbia University in 1917, Dietz joined the Philip Goodman Advertising Agency, where he was assigned to devise a trademark for Goldwyn Pictures. Dietz used Columbia's lion mascot as an inspiration for the Goldwyn studio's "roaring lion" trademark, which thereafter appeared at the beginning of each film, including those made after Goldwyn Pictures merged with two other studios in 1924 to become Metro-Goldwyn-Mayer (MGM) Corporation. Dietz also suggested the lion's accompanying Latin motto, "Ars Gratia Artis"—"Art for Art's Sake." Dietz himself joined Goldwyn Pictures in 1919 and soon became director of advertising and publicity, a post that he retained in MGM until his retirement in 1957.

Dietz wrote lyrics in his spare time and eventually wrote the words to more than 500 songs. He began this second career in 1923, but it was not until he teamed up with the song composer Arthur Schwartz in 1929 and the duo established their reputation with the musical revue *The Little Show* that his talents were recognized. The two men went on to collaborate in writing such popular Broadway musicals and revues as *Three's a Crowd* (1930), *The Band Wagon* (1931), *Flying Colors* (1932), *Revenge with Music* (1934), *At Home Abroad* (1935), *Inside U.S.A.* (1941), and *The Gay Life* (1961). Dietz also wrote an acclaimed English translation of Johann Strauss's operetta *Die Fledermaus* in 1950.

Dietz, Robert S., in full ROBERT SINCLAIR DIETZ (b. Sept. 14, 1914, Westfield, N.J., U.S.—d. May 19, 1995, Tempe, Ariz.), American geophysicist and oceanographer who set forth a theory of seafloor spreading in 1961.

Dietz was educated at the University of Illinois (B.S., 1937; M.S., 1939; Ph.D., 1941). After serving as an officer in the U.S. Army Air Corps during World War II, he became a civilian scientist with the U.S. Navy. In this capacity, he supervised the oceanographic research on Admiral Richard E. Byrd's last Antarctic expedition (1946–47). He subsequently served as oceanographer with several organizations, including the U.S. Coast and Geodetic Survey (1958–65) and the Atlantic Oceanography and Meteorology Laboratories (1970–77). He became professor of geology at Arizona State University, Tempe, in 1977.

Dietz's discovery in 1952 of the first fracture zone in the Pacific, which he related to deformation of the Earth's crust, led him to hypothesize that new crustal material is formed at oceanic ridges and spreads outward at a rate of several centimetres per year. Subsequent work confirmed this suggestion. He helped to redevelop the bathyscaphe *Trieste* of Swiss engineer Jacques Piccard, who descended about 7 miles (11 km) into the Pacific Ocean in it in 1960. Dietz also became known for his work in the fields of selenography (study of the Moon's physical features) and meteoritics, particularly for his suggestion that certain shock effects in rocks are indicative of meteorite impact.

Dieudonné, Jean, in full JEAN-ALEXANDRE-EUGÈNE DIEUDONNÉ (b. July 1, 1906, Lille, France—d. Nov. 29, 1992, Paris), French mathematician and educator known for his

writings on abstract algebra, functional analysis, topology, and his theory of Lie groups.

Dieudonné was educated in Paris, receiving both his bachelor's degree (1927) and his doctorate (1931) from the École Normale Supérieure. He was a founding member of the Nicolas Bourbaki (*q.v.*) group in the mid-1930s. After teaching at universities in Rennes and Nancy, France, and in São Paulo, Brazil, Dieudonné came to the United States in 1952 and taught mathematics at the University of Michigan and at Northwestern University. He returned to Paris to teach at the Institute of Advanced Scientific Studies (1959–64). He became professor of mathematics at the University of Nice in 1964, dean of the science faculty in 1965, and professor emeritus in 1970. In 1968 he was elected to the French Academy of Sciences.

Dieudonné's publications include *La Géométrie des groupes classiques* (1955), *Fondations de Modern Analysis* (1960), *Algèbre linéaire et géométrie élémentaire* (1964; "Linear Algebra and Elementary Geometry"), and *Éléments d'analyse*, 9 vol. (1968–82).

Dieulafoy, Marcel-Auguste (b. Aug. 3, 1844, Toulouse, France—d. Feb. 25, 1920, Paris), French archaeologist and civil engineer who excavated the palaces of the ancient Persian kings Darius I the Great and Artaxerxes II at Susa (modern Shūsh, Iran) in 1885 and gathered a large collection of archaeological fragments, which were placed in the Louvre.

Dieulafoy's published works include *L'Art antique de la Perse*, 5 vol. (1884–89; "The Ancient Art of Persia"), and *L'Acropole de Suse* (1890–92; "The Acropolis of Susa"). His wife, Jeanne Magre Dieulafoy (1851–1916), who accompanied him on the expedition, published *À Suse, journal des fouilles* (1888; "At Susa, Journal of Excavations"). She also discovered the ruins of the famed 12th-century mosque at Hasan, Morocco, in 1912.

Dievs, also called DEBESTĒVS (Latvian), Lithuanian DIEVAS, Old Prussian DEIVAS, in Baltic religion, the sky god. Dievs and Laima, the goddess of human fate, determine human destiny and world order. Dievs is a wooer of Saule, the sun. As pictured by the pre-Christian Balts, he is an Iron Age Baltic king who lives on a farmstead in the sky. Wearing a silver gown, pendants, and a sword, he occasionally rides down to earth, on horseback or in a horse-drawn chariot, to watch over farmers and their crops.

Dievs has two sons (Dieva dēli in Latvian; Dievo sūneliai in Lithuanian), who are known as the Heavenly Twins and the morning and evening stars. Like their Greek (Dioscuri) and Vedic (Aśvins, or Nāsatyas) counterparts, Dieva dēli are skilled horsemen. They associate with Saules meita, the daughter of the sun, and when she is sinking into the sea with only her crown still visible, Dieva dēli come to her rescue.

In name, *Dievs* is cognate with the Vedic *Dyaus-Pitṛ*, the Latin *Dies-piter* (*Jupiter*), and the Greek *Zeus*, denoting originally the bright, daylight sky.

Diez, Friedrich Christian (b. March 15, 1794, Giessen, Hesse-Darmstadt [Germany]—d. May 29, 1876, Bonn, Ger.), German-born language scholar who made the first major analysis of the Romance languages and thus founded an important branch of comparative linguistics.

As a student Diez acquired a deep interest in Italian poetry, but a visit to the great German poet J.W. von Goethe in 1818 directed his attention to exploring Provençal literature. As *Privatdozent*, or student-paid lecturer, at the University of Bonn from 1822, he published two important early works, one on Provençal troubadour poetry (1826) and the other on the lives and works of the troubadours (1829). After becoming professor of modern litera-

ture at Bonn in 1830, he turned increasingly to more general considerations of the Romance languages. Thus he came to produce his two great works, *Grammatik der romanischen Sprachen*, 3 vol. (1836–44; "Grammar of the Romance Languages"), and *Etymologisches Wörterbuch der romanischen Sprachen*, 2 vol. (1853; "Etymological Dictionary of the Romance Languages"). His work in the area of the Romance languages has been compared with the great achievement of Jacob Grimm in the field of Germanic languages.

Difaqane (African refugees): *see* Mfecane.

difference equation, mathematical equality involving the differences between successive values of a function of a discrete variable. A discrete variable is one that is defined or of interest only for values that differ by some finite amount, usually a constant and often 1; for example, the discrete variable x may have the values $x_0 = a$, $x_1 = a + 1$, $x_2 = a + 2$, . . . , $x_n = a + n$. The function y has the corresponding values $y_0, y_1, y_2, \dots, y_n$, from which the differences can be found:

$$\begin{aligned}\Delta y_0 &= y_1 - y_0 \\ \Delta y_1 &= y_2 - y_1 \\ &\dots \\ \Delta y_n &= y_{n+1} - y_n.\end{aligned}$$

Any equation that relates the values of Δy_i to each other or to x_i is a difference equation. In general, such an equation takes the form

$$y_i - a_i y_{i-1} = b_i.$$

Systematic methods have been developed for the solution of these equations and for those in which, for example, second-order differences are involved. A second-order difference is defined as

$$\begin{aligned}\Delta^2 y_i &= \Delta(\Delta y_i) = \Delta y_{i+1} - \Delta y_i \\ &= (y_{i+2} - y_{i+1}) - (y_{i+1} - y_i) \\ &= y_{i+2} - 2y_{i+1} + y_i.\end{aligned}$$

differential, in mathematics, an expression based on the derivative (*q.v.*) of a function, useful for approximating certain values of the function. The derivative of a function at the point x_0 , written as $f'(x_0)$, is defined as the limit as Δx approaches 0 of the quotient $\Delta y/\Delta x$, in which Δy is $f(x_0 + \Delta x) - f(x_0)$. Because the derivative is defined as the limit, the closer Δx is to 0, the closer will be the quotient to the derivative. Therefore, if Δx is small, then $\Delta y \approx f'(x_0)\Delta x$ (the wavy lines mean "is approximately equal to"). For example, to calculate $\sqrt{17}$, the function involved is $f(x) = \sqrt{x}$, which has a derivative equal to $1/2x^{-1/2}$. If x_0 is 16, then $f'(x_0)$ is $1/8$ and Δx is 1, giving an approximate value of $1/8$ for Δy . Because $f(16)$ is 4, it follows that $f(17)$, or $\sqrt{17}$, is approximately 4.125, the actual value being 4.123 to three decimals.

differential analyzer, computing device for solving differential equations. Its principal components perform the mathematical operation of integration (*see also* integrator).

The American electrical engineer Vannevar Bush and others at the Massachusetts Institute of Technology invented the first continuous integrator, later called a differential analyzer, during the early 1930s. Its integrators consisted of replaceable shafts, gears, wheels, and disks and required much manual setting up. The analog computer (*q.v.*) operates electronically and faster (although not always as accurately) and accomplishes the same operations with components that take up less space. The inherent lack of precision has been rectified in some cases by use of digital counting devices, giving rise to a subclass of these machines known as digital differential analyzers.

differential equation, mathematical statement containing one or more derivatives, that is, terms representing the relationships between the rates of change of continuously

varying quantities. Differential equations are very common in science and engineering, other fields of quantitative study. The solution of a differential equation is, in general, an algebraic equation expressing the functional dependence of one variable upon one or more others; it ordinarily contains constant terms that are not present in the original differential equation.

A brief treatment of differential equations follows. For full treatment, *see* MACROPAEDIA: Analysis (in Mathematics).

Differential equations are classified into several broad categories, and these are in turn further divided into many subcategories. The most important categories are those of the so-called ordinary differential equations and the so-called partial differential equations. When the function involved in the equation depends upon only a single variable, its derivatives are ordinary derivatives and the differential equation is classed as an ordinary differential equation. If, on the other hand, the function depends upon several independent variables, so that its derivatives are partial derivatives, then the differential equation is classed as a partial differential equation. The following are examples of ordinary differential equations:

$$\frac{dy}{dt} = -ky,$$

$$m \frac{d^2y}{dt^2} = -k^2y,$$

$$\left[1 + \left(\frac{dy}{dx} \right)^2 \right] \frac{d^3y}{dx^3} - 3 \frac{dy}{dx} \left(\frac{d^2y}{dx^2} \right)^2 = 0.$$

In these, y stands for the function, and either t or x is the independent variable. The symbols k and m are used here to stand for specific constants.

Whichever the type may be, a differential equation is said to be of the n th order if it involves a derivative of the n th order but no derivative of an order higher than this. The equation

$$\frac{\partial u}{\partial t} = k^2 \left[\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} \right]$$

is an example of a partial differential equation of the second order. The theories of ordinary and partial differential equations are markedly different, and for this reason the two categories are treated separately.

Instead of a single differential equation, the object of study may be a simultaneous system of such equations. The formulation of the laws of dynamics frequently leads to such systems. In many cases, a single differential equation of the n th order is advantageously replaceable by a system of n simultaneous equations each of which is of the first order.

An ordinary differential equation in which, for example, the function and the independent variable are denoted by y and x is in effect an implicit summary of the essential characteristics of y as a function of x . These characteristics would presumably be more accessible to analysis if an explicit formula for y could be produced. Such a formula, or at least an equation in x and y (involving no derivatives) that is deducible from the differential equation, is called a solution of the differential equation. The process of deducing a solution from the equation by the applications of algebra and the calculus is called that of solving or integrating the equation. It should be noted, however, that the differential equations that can be integrated form but a small minority. The chances are large, in the instance of a differential equation selected at random, that the equation is itself the simplest mode of summarizing the characteristics of the function and that even theoretically no solving formula in the usual sense exists. In such instances, the function must be studied by indirect methods. Even its existence must

be proved when there is no possibility of producing it for inspection.

differential equation, partial: *see* partial differential equation.

differential gear, in automotive mechanics, gear arrangement that permits power from the engine to be transmitted to a pair of driving wheels, dividing the force equally between them but permitting them to follow paths of different lengths, as when turning a corner or traversing an uneven road. On a straight road the wheels rotate at the same speed; when turning a corner the outside wheel has farther to go and will turn faster than the inner wheel if unrestrained.

The conventional automobile differential was invented in 1827 by a Frenchman, Onésiphore Pecqueur. It was used first on steam-driven vehicles and was a well-known device when internal-combustion engines appeared at the end of the 19th century.

The elements of the Pecqueur differential are shown in the Figure. The power from the transmission is delivered to the bevel ring gear by the drive-shaft pinion, both of which are held in bearings (not shown) in the rear-axle housing. The case is an open boxlike structure that is bolted to the ring gear and contains bearings to support one or two pairs of diametrically opposite differential bevel pinions. Each wheel axle is attached to a differential side gear, which meshes with the differential pinions. On a straight road the wheels and the side gears rotate at the same speed, there is no relative motion between the differential side gears and pinions, and they all rotate as a unit with the case and ring gear. If the vehicle turns to the left, the right-hand wheel will be forced to rotate faster than the left-hand wheel, and the side gears and the pinions will rotate relative to one another. The ring gear rotates at a speed that is equal to the mean speed of the left and right wheels. If the wheels are jacked up with the transmission in neutral and one of the wheels is turned, the opposite wheel will turn in the opposite direction at the same speed.

The torque (turning moment) transmitted to the two wheels with the Pecqueur differential is the same. Consequently, if one wheel slips, as in ice or mud, the torque to the other wheel is reduced. This disadvantage can be over-

Automobile differential

come somewhat by the use of a limited-slip differential. In one version a clutch connects one of the axles and the ring gear. When one wheel encounters low traction, its tendency to spin is resisted by the clutch, thus providing greater torque for the other wheel.

differential geometry, field of mathematics in which the calculus is applied to geometry. The type of this geometry called "local" deals mainly with properties in a limited domain around a point. It was thoroughly investigated in the 19th century after it was initiated in the 18th century by the European mathematicians Leonhard Euler and Gaspard Monge. With it are connected the names of Carl Friedrich Gauss, Pierre-Ossian Bonnet, Jean-Frédéric Frenet, and Eugenio Beltrami. Considerations of finite parts of surfaces, or surfaces (and curves) as a whole, are the concern of integral geometry, or global geometry, which has been further developed in the 20th century by Wilhelm Blaschke and others. This specialty includes, for example, theorems on closed geodesic lines on surfaces, especially ovaloids (egglike surfaces).

A brief treatment of differential geometry follows. For full treatment, *see* MACROPAEDIA: Geometry.

A simple example of the techniques of differential geometry is the determination of the tangent to a plane curve at some chosen point on the curve. The procedure is equivalent to selecting—from all the lines passing through the chosen point—that line which has the same slope as the curve at that point. The methods of analytic geometry make it possible to write algebraic equations for the curve and for a line passing through the desired point and any nearby point on the curve; the methods of the calculus identify the line that has the required slope.

Similar operations may be extended to the calculation of the curvature and length of arc of curves and of analogous properties of surfaces in spaces of any number of dimensions.

differential psychology, branch of psychology that deals with individual and group differences in behaviour. Charles Darwin's studies of the survival capabilities of different species and Sir Francis Galton's researches on individual visual and auditory skills, as well as more recent experiments, have shown that both individual and group differences are quantitative rather than qualitative. Persons do not fall into sharply separated types, such as bright and dull, maladjusted and normal, introvert and extrovert. On the contrary, in all psychological characteristics, individuals vary by degree along a continuous scale. For most traits, the distribution approximates the bell-shaped normal probability curve, with the greatest clustering of cases near the centre of the range and a gradual decrease in numbers as the extremes are approached. Individual differences in behavioral characteristics are not limited to the human species; they occur throughout the animal scale. Investigations of animal behaviour, from unicellular organisms to anthropoid apes, reveal wide individual differences in learning, motivation, emotionality, and other traits. So large are these differences that the distributions overlap even when widely separated species are compared.

differential thermal analysis (DTA), in analytical chemistry, a technique for identifying and quantitatively analyzing the chemical composition of substances by observing the thermal behaviour of a sample as it is heated. The technique is based on the fact that as a substance is heated, it undergoes reactions and phase changes that involve absorption or emission of heat. In DTA the temperature of the test material is measured relative to that of an adjacent inert material. A thermocouple

imbedded in the test piece and another in the inert material are connected so that any differential temperatures generated during the heating cycle are graphically recorded as a series of peaks on a moving chart. The amount of heat involved and temperature at which these changes take place are characteristic of individual elements or compounds; identification of a substance, therefore, is accomplished by comparing DTA curves obtained from the unknown with those of known elements or compounds. Moreover, the amount of a substance present in a composite sample will be related to the area under the peaks in the graph, and this amount can be determined by comparing the area of a characteristic peak with areas from a series of standard samples analyzed under identical conditions. The DTA technique is widely used for identifying minerals and mineral mixtures.

differentiation, in mathematics, process of finding the derivative (*q.v.*), or rate of change, of a function. In contrast to the abstract nature of the theory behind it, the practical technique of differentiation can be carried out by purely algebraic manipulations, using three basic derivatives, four rules of operation, and a knowledge of how to manipulate functions.

The three basic derivatives are: (1) for algebraic functions, $D(x^n) = nx^{n-1}$, in which n is any real number; (2) for trigonometric functions, $D(\sin x) = \cos x$; and (3) for exponential functions, $D(e^x) = e^x$.

For functions built up of combinations of these classes of functions, the theory provides the following basic rules for differentiating the sum, product, or quotient of any two functions $f(x)$ and $g(x)$ the derivatives of which are known: $D(af + bg) = aDf + bDg$ (sums); $D(fg) = fDg + gDf$ (products); and $D(f/g) = (gDf - fDg)/g^2$ (quotients).

The other basic rule, called the chain rule, provides a way to differentiate a composite function. If $f(x)$ and $g(x)$ are two functions, the composite function $f(g(x))$ is calculated for a value of x by first evaluating $g(x)$ and then evaluating the function f at this value of $g(x)$; for instance, if $f(x) = \sin x$ and $g(x) = x^2$, then $f(g(x)) = \sin x^2$, while $g(f(x)) = (\sin x)^2$. The chain rule states that the derivative of a composite function is given by a product, as $D(f(g(x))) = Df(g(x)) \cdot Dg(x)$. In words, the first factor on the right, $Df(g(x))$, indicates that the derivative of $Df(x)$ is first found as usual, and then x , wherever it occurs, is replaced by the function $g(x)$. In the example of $\sin x^2$, the rule gives the result $D(\sin x^2) = D(\sin x^2) \cdot D(x^2) = (\cos x^2) \cdot 2x$.

differentiator, a device or set of components for performing the mathematical operation of differentiation—*i.e.*, supplying an output proportional to the derivative of the input with respect to one or more variables. The many common examples of mechanical differentiators in which a displacement is differentiated with respect to time include speedometers and generators. In such devices, the derivative is frequently measured by deflections of spring-loaded elements.

There are also electronic differentiators, or electrical differentiating circuits. The Figure shows a differentiator based on an electrical analog. For a time-varying input, if the ca-

pacitive reactance X_C shown in the schematic diagram is very large compared with the resistance R , the current, and hence output voltage E_{OUT} appearing across R , will lead the phase of the input voltage E_{IN} by almost 90° . Thus the output voltage E_{OUT} is the time derivative of the input voltage E_{IN} , $E_{OUT} = dE_{IN}/dt$.

diffraction, the spreading of waves around obstacles. Diffraction takes place with sound; with electromagnetic radiation, such as light, X-rays, and gamma rays; and with very small moving particles such as atoms, neutrons, and electrons, which show wavelike properties. One consequence of diffraction is that sharp shadows are not produced. The phenomenon is the result of interference (*i.e.*, when waves are superimposed, they may reinforce or cancel each other out) and is most pronounced when the wavelength of the radiation is comparable to the linear dimensions of the obstacle. When sound of various wavelengths or frequencies is emitted from a loudspeaker, the loudspeaker itself acts as an obstacle and casts a shadow to its rear so that only the longer bass notes are diffracted there. When a beam of light falls on the edge of an object, it will not continue in a straight line but will be slightly bent by the contact, causing a blur at the edge of the shadow of the object; the amount of bending will be proportional to the wavelength. When a stream of fast particles impinges on the atoms of a crystal, their paths are bent into a regular pattern, which can be recorded by directing the diffracted beam onto a photographic film.

diffraction grating, component of optical devices consisting of a surface ruled with close, equidistant, and parallel lines for the purpose of resolving light into spectra. A grating is said to be a transmission or reflection grating according to whether it is transparent or mirrored—that is, whether it is ruled on glass or on a thin metal film deposited on a glass blank. Reflection gratings are further classified as plane or concave, the latter being a spherical surface ruled with lines that are the projection of equidistant and parallel lines on an imaginary plane surface. The advantage of a concave grating over a plane grating is its ability to produce sharp spectral lines without the aid of lenses or additional mirrors. This makes it useful in the infrared and ultraviolet regions in which these radiations would otherwise be absorbed upon passage through a lens.

The lines on gratings are made by an extremely precise machine called a ruling engine, which uses a diamond-tipped tool to press thousands of very fine, shallow lines onto a highly polished surface. Newer techniques rule the lines photographically, using laser interferometry.

A diffraction grating is able to disperse a beam of various wavelengths into a spectrum of associated lines because of the principle of diffraction: in any particular direction, only those waves of a given wavelength will be conserved, all the rest being destroyed because of interference with one another. Gratings give exceptionally high resolutions of spectral lines. The resolving power (R) of an optical instrument represents the ability to separate closely spaced lines in a spectrum and is equal to the wavelength λ divided by the smallest difference ($\Delta\lambda$) in two wavelengths that can be detected; *i.e.*, $R = \lambda/\Delta\lambda$. Thus, for a grating 10 centimetres wide and ruled with 10,000 lines per centimetre, the resolution in the first diffraction order would be 100,000. For a wavelength emission in the ultraviolet, say $\lambda = 300$ nanometres (3×10^{-7} metre), a wavelength difference of $\Delta\lambda = 3 \times 10^{-12}$ metre (about $1/100$ the diameter of an atom) should be theoretically possible.

diffusion, process resulting from random motion of molecules by which there is a net flow

of matter from a region of high concentration to a region of low concentration. A familiar example is the perfume of a flower that quickly permeates the still air of a room.

Heat conduction in fluids involves thermal energy transported, or diffused, from higher to lower temperature. Operation of a nuclear reactor involves the diffusion of neutrons through a medium that causes frequent scattering but only rare absorption of neutrons.

The rate of flow of the diffusing substance is found to be proportional to the concentration gradient. If j is the amount of substance passing through a reference surface of unit area per unit time, if the coordinate x is perpendicular to this reference area, if c is the concentration of the substance, and if the constant of proportionality is D , then $j = -D(dc/dx)$; dc/dx is the rate of change of concentration in the direction x , and the minus sign indicates the flow is from higher to lower concentration. D is called the diffusivity and governs the rate of diffusion.

diffusion chamber, simple form of cloud chamber, a device used for radiation detection (*see* cloud chamber).

Digambara (Sanskrit: "Sky-clad"), in Jainism, one of the two principal sects, whose ascetics, shunning all property, wear no clothes. The ascetics of the other sect, the Śvetāmbara (*q.v.*; "White-robed"), wear only simple white loin cloths or robes.

The schism that gave rise to the two sects is traditionally said to have taken place following a migration of Jaina monks southward from the Ganges River or from Ujjain to Karnaṭaka during a serious famine in the reign of Candragupta Maurya. Bhadrabāhu, the leader of the emigrants, insisted on the observance of nudity, thus following the example set by Mahāvira, the last of the Jaina saviours. Śhūlabhadra, the leader of the monks who remained behind in the north, allowed the wearing of white garments, possibly as a concession to the hardships and confusion caused by the famine.

The philosophical doctrines of the two groups never significantly differed, and their members have continued to intermarry. Since the northern and southern branches lived at a distance from one another, however, variations in their ritual, mythology, and literature did arise. The most serious issue, the question of whether it was possible for a monk who owned property (*e.g.*, wore clothes) to achieve moksha (spiritual release), led to the division into two sects in AD 80 (according to the Śvetāmbaras, AD 83).

Other points of difference held by the Digambara are (1) the belief that the perfect saint (*kevalin*) needs no food to stay alive; (2) the belief that Mahāvira never married; (3) the view that no woman can reach moksha without being reborn as a man; and (4) the representation in their images of every Tirthāṅkara (Jain saviour) as always naked, without ornaments, and with downcast eyes. Also, the Digambara do not recognize the Śvetāmbara canon of religious texts but maintain that the early literature was gradually forgotten and lost completely by the 2nd century AD.

The Digambara influence in southern India during the European Middle Ages was considerable, but it diminished in importance in that area as Hindu devotional Śaivism and Vaiṣṇavism grew. The sect continues mainly in southern Mahārāshtra and Karnaṭaka states.

Digby, town, seat of Digby county, western Nova Scotia, Canada. It is situated on the isthmus of Digby Neck Peninsula, at the southern end of Annapolis Basin, an inlet of the Bay of Fundy.

The original settlement in 1766 by New

Englanders was destroyed by pirates, but in 1783 British admiral Robert Digby convoyed a group of United Empire Loyalists to resettle the site. Digby is now a popular summer resort and fishing port; it has a large scallop fishing fleet. Industries include lumbering, woodworking, and fish processing, especially of herring, known as "Digby chickens," and scallops. The town is also the southern terminus of a car ferry from Saint John, N.B., 45 miles (72 km) to the north-northwest. Inc. 1890. Pop. (1991) 2,311.

Digby, George: see Bristol, George Digby, 2nd Earl of.

Digby, John: see Bristol, John Digby, 1st Earl of.

Digby, Sir Kenelm (b. July 11, 1603, Gayhurst, Buckinghamshire, Eng.—d. June 11, 1665, London), English courtier, philosopher, diplomat, and scientist of the reign of Charles I.

Digby was the son of Sir Everard Digby, who was executed in 1606 for his part in the Gunpowder Plot (a conspiracy of a few Roman Catholics to destroy James I and the members of Parliament), and was brought up by his mother as a Roman Catholic. He left the University of Oxford in 1620 without taking a degree and was induced to go abroad by his mother, who opposed his love for Venetia, daughter of Sir Edward Stanley; she had been a childhood playmate and had become a woman of beauty and intellectual attainment. In 1623 in Madrid, Digby was appointed to the household of Prince Charles, who had just arrived there. Returning to England the same year, he was knighted by James I and appointed gentleman of the privy chamber to Charles. In 1625 he married Venetia Stanley.

In an attempt to win favour at court by some large action, Digby embarked as a privateer in December 1627 to attack for booty French ships that were anchored in the Venetian harbour of Scanderon (now Iskenderun, Turkey). He returned to England in February 1628, in triumph, though the government felt called upon to disavow his actions because of threats of reprisals against English merchants. Lady Digby died in 1633, and he retired to Gresham College, where he occupied himself with chemical experiments for two years.

After 1635 Digby associated himself with the entourage of Henrietta Maria, Charles I's Catholic queen, and supported Charles's expedition against the Presbyterian Scots in 1639–40; for this, Digby was summoned by Parliament as a Catholic recusant and appeared before the bar of the House of Commons in 1641. He then went to France, where in a duel he killed a French lord for insulting Charles I. Returning to England, he was imprisoned by the Commons (1642–43). On his release he went to Paris, where he published his chief philosophical works, *Of the Nature of Bodies* and *Of the Nature of Mans Soule* (both 1644).

Digby again returned to England, and Henrietta Maria appointed him her chancellor; he was sent on two abortive missions to Pope Innocent X in Rome for aid in the Royalist cause in the English Civil Wars. Digby promised the conversion of King Charles and his chief aides. After banishment from England by a suspicious Parliament in 1649, he was allowed to return in 1654 and tried to obtain full toleration for Catholics from Oliver Cromwell. At the restoration of the monarchy, on May 8, 1660, he was confirmed as Henrietta's chancellor and was on the council of the Royal Society when its charter was granted in 1663. In January 1664 he was banished from court on grounds that he had interfered on behalf of a nobleman who had fallen into royal disfavour. Digby spent the remainder of his life in literary and scientific pursuits.

Digenis Akritas, also called DIGENIS AKRITAS BASILEIOS, Byzantine epic hero celebrated in folk ballads (Akritic ballads) and in an epic

relating his parentage, boyhood adventures, manhood, and death. Based on a historical character who died about 788, the epic, a blend of Greek, Byzantine, and Oriental motifs, originated in the 10th century and was popularized by itinerant folksingers; it was recorded in several versions from the 12th to the 17th century, the oldest being a linguistic mixture of popular and literary language.

Digenis Akritas, the ideal medieval Greek hero, is a bold warrior of the Euphrates frontier, the son of a Saracen emir converted to Christianity by the daughter of a Byzantine general; he was a proficient warrior by the age of three and spent the rest of his life defending the Byzantine Empire from frontier invaders. The feeling for nature and strong family affections that permeate the epic anticipate the great Cretan national romance, *Erôtókritios* (mid-17th century) by Vitzéntzos Kornáros, and much modern Greek popular poetry.

Digest (in Roman law): see Pandects.

digestion, process by which food is dissolved and chemically converted so that it can be absorbed by the cells of an organism and used to maintain vital body functions. In vertebrates, the main organs of the digestive tract are the mouth, the stomach, and the small and large intestines. Also important are the liver and pancreas, which produce enzymes that contribute to the breakdown of food in the digestive tract. For a depiction of some of the structures that make up the human digestive system, see the colour Trans-Vision in the PROPAEDIA: Part Four, Section 421.

A brief treatment of digestion and digestive systems follows. For full treatment, see MACROPAEDIA: Digestion and Digestive Systems.

Complex carbohydrates (polysaccharides and starches), fats, and proteins must be converted into simpler compounds before they can be assimilated into cells. During digestion, these organic compounds are reduced by hydrolytic enzymes, which split the long molecular chains by adding water molecules.

Vacuolar digestive systems, found mostly in unicellular organisms, are the simplest forms of digestion. Food is ingested and passed through a cell in bubblelike chambers called vacuoles. Enzyme-containing organelles, or lysosomes, fuse with the vacuoles, and the enzymes convert the food into simpler compounds that can be assimilated into cellular material. After a vacuole has crossed the cell, it is expelled along with any undigested matter.

One of the simplest groups of multicellular animals—the sponges—have slightly more elaborate digestive processes called channel-network systems. In these cases, whiplike structures called flagella direct water and food along channels lined with cells that capture food particles and engulf them in vacuoles in which digestion occurs. In all other multicellular animals, special cells digest food for the entire organism. The bodies of hydra, for example, are composed of two cell layers: an outer layer (epithelium), which performs protective and sensory functions, and an inner layer (gastrodermis), responsible for digestion. The prey of a hydra is partly digested in a central cavity and is completely broken down within the vacuoles of the gastrodermal cells. Such systems are called saccular (*i.e.*, the digestive cavity is a sac with a single opening that serves as both a mouth and anus).

The human digestive tract. Most higher animals, including all vertebrates, have digestive tracts, or alimentary canals, through which food passes. Human digestion begins in the mouth. There the food is chewed and mixed with saliva, which adds moisture and contains the enzyme amylase that begins to break down starches. The tongue kneads the food into a smooth ball (bolus), which is then swallowed. The bolus passes through the pharynx and esophagus into the stomach, propelled by peri-

staltic muscular contractions. In the stomach the food is mixed by peristaltic contractions (about three per minute) with highly acidic gastric juices secreted into the stomach. The hormone gastrin stimulates the secretion of these juices, which contain water, inorganic salts, hydrochloric acid, mucin, and several enzymes, the most abundant of which is pepsin. Pepsin breaks protein molecules into smaller molecules called polypeptides.

The food, now in a semiliquid state called chyme, passes from the stomach into the duodenum, the first section of the small intestine, where the greatest part of digestion takes place. The chyme is subjected to the actions of a large number of enzymes, some secreted by the pancreas (which is connected to the duodenum by a duct) and some produced by glands in the intestinal wall. Each enzyme acts on specific food molecules. For example, amylase, maltase, lactase, and sucrose complete the digestion of carbohydrates; trypsin, chymotrypsin, carboxypeptidase, aminopeptidase, and dipeptidase break down proteins; and lipase hydrolyzes fat molecules. Bile, which is produced by the liver, also empties into the duodenum; it contains salts that break up (emulsify) fat globules, thereby exposing fat molecules to the enzymatic action of lipase. By the time this process has been completed, the carbohydrates have been broken down into simple sugars (monosaccharides), the proteins into amino acids, and the fats into glycerol and fatty acids. These simple molecules are then absorbed into the circulatory system through countless microscopic projections of the intestinal wall called villi as the material moves through the jejunum and ileum (the remaining sections of the small intestine).

Substances that cannot be digested, such as cellulose (plant fibre), pass into the colon, or large intestine. There, water and ions such as sodium and chloride are reabsorbed, and the remaining solid material (feces) is held until it is expelled through the anus. Common diseases of the human digestive tract include infections, inflammations, ulcers, and cancers.

The enteric nervous system. Movements in the gastrointestinal tract are controlled by a network of nerve fibres collectively called the enteric nervous system. The nervous system's regulation of digestive functions is complex and not completely understood. Two major nerve centres are involved: the myenteric plexus (Auerbach's plexus) and the submucosal plexus (Meissner's plexus). The myenteric plexus is situated between the circular muscle layer and the longitudinal muscle layer in the lower esophagus, stomach, and intestines. The submucosal plexus, as its name implies, is located in the submucosal tissue, which connects the surface mucous membrane lining to the deeper muscle layers in the stomach and intestines.

The myenteric plexus receives input from the vagus nerve and stimulates the muscles to contract in peristaltic waves, thereby pushing food through the digestive tract. The myenteric plexus also is thought to preserve muscle tone throughout the intestine walls, promote secretions of intestinal juices, and allow muscular constrictions (sphincters) to open, thus permitting food to pass from one part of the digestive system to another.

The function of the submucosal plexus is not as clearly defined. In the stomach its role may be partly inhibitory, working against the myenteric plexus to control the muscular contractions more finely. In the intestines it is generally believed to work in accord with the myenteric plexus in producing peristaltic waves and increasing digestive secretions. It also is thought to regulate the local blood flow and to affect the transport of water and electrolytes.

Digger, any of a group of agrarian communists who flourished in England in 1649–50 and were led by Gerrard Winstanley (*q.v.*) and William Everard. In April 1649 about 20 poor men assembled at St. George's Hill, Surrey, and began to cultivate the common land. These Diggers held that the English Civil Wars had been fought against the king and the great landowners; now that Charles I had been executed, land should be made available for the very poor to cultivate. (Food prices had reached record heights in the late 1640s.) The numbers of the Diggers more than doubled during 1649. Their activities alarmed the Commonwealth government and roused the hostility of local landowners, who were rival claimants to the common lands. The Diggers were harassed by legal actions and mob violence, and by the end of March 1650 their colony was dispersed. The Diggers themselves abjured the use of force. The Diggers also called themselves True Levelers, but their communism was denounced by the leaders of the Levelers.

Dighenis: *see* Grivas, Georgios.

digit, in anatomy, finger or toe of land vertebrates, the skeleton of which consists of small bones called phalanges. The tips of the digits are usually protected by keratinous structures, such as claws, nails, or hoofs, which may also be used for defense or manipulation. Digits are numbered one through five, beginning with the inside digit (thumb) when the palm (paw) is face downward.

In many species the number of digits has been reduced during the course of evolution. Amphibians and birds typically have four digits on each foot, amphibians having lost digit one (thumb) and birds digit five. Reptiles usually have five digits. Many phalanges have been lost from the bird's wing; the remainder are often elongated for support in flight. The number of digits in mammals varies greatly. In those with five digits (*e.g.*, primates, raccoons), the thumb has two phalanges; all other digits have three. In the horse only the third digit remains, covered at the tip by a single hoof. In cattle and other split-hoofed animals, digits three and four remain.

The number of phalanges may be multiplied in the fins of sea mammals. In bats the phalanges of digits two to five, and other arm bones, are elongated and support a fleshy wing; the thumb is short and free and carries a claw.

Primates have five digits, and most have developed fingernails and toenails in the place of claws and hoofs. These digits tend to be capable of much independent, manipulative action. The human foot is specialized for bipedal locomotion—the toes are shortened, relatively immovable, and nonmanipulative.

digit malformation, in human physiology, any of the isolated anomalies of the digits (fingers or toes) in an otherwise normal individual or as one symptom of a more generalized genetic abnormality. In polydactyly, having more than the normal number of digits, the extra digit is smaller than normal and usually at the outside of the hand or foot; it may be removed surgically. Polydactyly sometimes also occurs in various genetic syndromes, including the Ellis-van Creveld syndrome and chromosomal trisomy 13 (D_1 -trisomy). In syndactyly the digits are fused or webbed, and it also is treated surgically. Syndactyly is a common finding in many genetic disorders. Brachydactyly, or abnormally short digits, may result from underdevelopment or absence of some of the phalanges or metacarpals and metatarsals.

Long, spidery digits (arachnodactyly) are typical in Marfan's syndrome.

digital computer, any of a class of devices capable of solving problems by processing information in discrete form. It operates on data, including magnitudes, letters, and symbols, that are expressed in binary form—*i.e.*, using only the two digits 0 and 1. By counting, comparing, and manipulating these digits or their combinations according to a set of instructions held in its memory, a digital computer can perform such tasks as to control industrial processes and regulate the operations of machines; analyze and organize vast amounts of business data; and simulate the behaviour of dynamic systems (*e.g.*, global weather patterns and chemical reactions) in scientific research.

A brief treatment of digital computers follows. For full treatment, *see* MACROPAEDIA: Computers.

Functional elements. A typical digital computer system has four basic functional elements: (1) input-output equipment, (2) main memory, (3) control unit, and (4) arithmetic-logic unit. Any of a number of devices is used to enter data and program instructions into a computer and to gain access to the results of the processing operation. Common input devices include keyboards and optical scanners; output devices include printers and cathode-ray tube and liquid-crystal display monitors. The information received by a computer from its input unit is stored in the main memory or, if not for immediate use, in an auxiliary storage device. The control unit selects and calls up instructions from the memory in appropriate sequence and relays the proper commands to the appropriate unit. It also synchronizes the varied operating speeds of the input and output devices to that of the arithmetic-logic unit (ALU) so as to ensure the proper movement of data through the entire computer system. The ALU performs the arithmetic and logic algorithms selected to process the incoming data at extremely high speeds—in many cases in nanoseconds (billionths of a second). The main memory, control unit, and ALU together make up the central processing unit (CPU) of most digital computer systems, while the input-output devices and auxiliary storage units constitute peripheral equipment.

Development of the digital computer. Blaise Pascal of France and Gottfried Wilhelm Leibniz of Germany invented mechanical digital calculating machines during the 17th century. The English inventor Charles Babbage, however, is generally credited with having conceived the first automatic digital computer. During the 1830s Babbage devised his so-called Analytical Engine, a mechanical device designed to combine basic arithmetic operations with decisions based on its own computations. Babbage's plans embodied most of the fundamental elements of the modern digital computer. For example, they called for sequential control—*i.e.*, program control that included branching, looping, and both arithmetic and storage units with automatic print-out. Babbage's device, however, was never completed and was forgotten until his writings were rediscovered over a century later.

Of great importance in the evolution of the digital computer was the work of the English mathematician and logician George Boole. In various essays written during the mid-1800s, Boole discussed the analogy between the symbols of algebra and those of logic as used to represent logical forms and syllogisms. His formalism, operating on only 0 and 1, became the basis of what is now called Boolean algebra (*q.v.*), on which computer switching theory and procedures are grounded.

John V. Atanasoff, an American mathematician and physicist, is credited with building the first electronic digital computer, which he constructed from 1939 to 1942 with the

assistance of his graduate student Clifford E. Berry. Konrad Zuse, a German engineer acting in virtual isolation from developments elsewhere, completed construction in 1941 of the first operational program-controlled calculating machine (Z3). In 1944 Howard Aiken and a group of engineers at International Business Machines Corporation completed work on the Harvard Mark I, a machine whose data-processing operations were controlled primarily by electric relays (switching devices).

Since the development of the Harvard Mark I, the digital computer has evolved at a rapid pace. The succession of advances in computer equipment, principally in logic circuitry, is often divided into generations, with each generation comprising a group of machines that share a common technology.

In 1946 J. Presper Eckert and John W. Mauchly, both of the University of Pennsylvania, constructed ENIAC (an acronym for *electronic numerical integrator and computer*), a digital machine and the first general-purpose, electronic computer. Its computing features were derived from Atanasoff's machine; both computers included vacuum tubes instead of relays as their active logic elements, a feature that resulted in a significant increase in operating speed. The concept of a stored-program computer was introduced in the mid-1940s, and the idea of storing instruction codes as well as data in an electrically alterable memory was implemented in EDVAC (*electronic discrete variable automatic computer*).

The second computer generation began in the late 1950s, when digital machines utilizing transistors became commercially available. Although this type of semiconductor device had been invented in 1948, more than 10 years of developmental work was needed to render it a viable alternative to the vacuum tube. The small size of the transistor, its greater reliability, and its relatively low power consumption made it vastly superior to the tube. Its use in computer circuitry permitted the manufacture of digital systems that were considerably more efficient, smaller, and faster than their first-generation ancestors.

The late 1960s and '70s witnessed further dramatic advances in computer hardware. The first was the fabrication of the integrated circuit, a solid-state device containing hundreds of transistors, diodes, and resistors on a tiny silicon chip. This microcircuit made possible the production of mainframe (large-scale) computers of higher operating speeds, capacity, and reliability at significantly lower cost. Another type of third-generation computer that developed as a result of microelectronics was the minicomputer, a machine appreciably smaller than the standard mainframe but powerful enough to control the instruments of an entire scientific laboratory.

The development of large-scale integration (LSI) enabled hardware manufacturers to pack thousands of transistors and other related components on a single silicon chip about the size of a baby's fingernail. Such microcircuitry yielded two devices that revolutionized computer technology. The first of these was the microprocessor, which is an integrated circuit that contains all the arithmetic, logic, and control circuitry of a central processing unit. Its production resulted in the development of microcomputers, systems no larger than portable television sets yet with substantial computing power. The other important device to emerge from LSI circuitry was the semiconductor memory. Consisting of only a few chips, this compact storage device is well-suited for use in minicomputers and microcomputers. Moreover, it has found use in an increasing number of mainframes, particularly those designed for high-speed applications, because of its fast-access speed and large storage capacity.

By the beginning of the 1980s integrated circuitry had advanced to very large-scale in-

tegration (VLSI). This design and manufacturing technology greatly increased the circuit density of microprocessor, memory, and support chips—*i.e.*, those that serve to interface microprocessors with input-output devices. By the 1990s some VLSI circuits contained more than 3 million transistors on a silicon chip less than 0.3 square inch (2 square cm) in area.

The digital computers of the 1980s and '90s employing LSI and VLSI technologies are frequently referred to as fourth-generation systems. Many of the microcomputers produced during the 1980s were equipped with a single chip on which circuits for processor, memory, and interface functions were integrated. *See also* supercomputer.

digital sound recording, method of preserving sound in which audio signals are transformed into a series of pulses that correspond to patterns of binary digits (*i.e.*, 0's and 1's) and are recorded as such on the surface of a magnetic tape or optical disc. A digital system samples a sound's wave form, or value, several thousand times a second and assigns numerical values in the form of binary digits to its amplitude at any given instant. A typical digital recording system is equipped with an analog-to-digital converter that transforms two channels of continuous audio signals into digital information, which is then recorded by a high-speed tape or disc machine. The system uses a digital-to-analog converter that reads the encoded information from the recording medium and changes it back into audio signals that can be used by the amplifier of a conventional stereo sound system.

Digital recording provides higher-fidelity sound reproduction than do ordinary recording methods, largely because audio signals converted into simple pulse patterns are virtually immune to the residual noise and distortion that are characteristic of analog communication channels and sound recording media. In addition, many digital recording systems are designed to detect and eliminate interfering signals. In the 1980s digital compact disc recordings became available that were played by using a laser beam to optically scan digital information encoded on the disc's surface. In the late 1980s digital audio tape (DAT) recorders using magnetic tape cassettes became available for audio reproduction and recording. The DAT recorder converts audio signals into digital data on a magnetic tape by means of a microprocessor and converts the data back into analog audio signals that can be used by the amplifier of a conventional stereo sound system. The early 1990s saw the introduction of digital compact cassette (DCC) recorders, which were similar to DAT recorders but could play the older analog tape cassettes in addition to similarly shaped digital cassettes. *See also* sound recording.

digitalis, substance obtained from the dried leaves of the common foxglove (*Digitalis purpurea*) and used as a drug that strengthens contractions of the heart muscle. It is most commonly used to restore adequate circulation in patients suffering from congestive heart failure, particularly as caused by arteriosclerosis or hypertension. The drug is also used to slow the rate of ventricular contraction in patients with atrial fibrillation or flutter. Digitalis directly increases the contractile power of the heart muscle, enabling a disease-weakened heart to keep up with the body's demand for heart action when the organ would otherwise be unable to. The drug's other effects include a slowing of the rate of the heartbeat, an increase in the heart's output, and a decrease in the size of the heart.

The first physician to prescribe digitalis was the English physician and botanist William Withering (1741–99), who used it in the treatment of edema (dropsy). In *An Account of the Foxglove, and Some of Its Medical Uses* (1785), he summarized the results of his ex-

tensive clinical trials of the drug and described the symptoms of digitalis toxicity. The active principles in digitalis belong to a group of steroids called the cardiac glycosides. Their dosage must be determined with exceptional care because the lethal dose may be only three times the effective dose. Digitoxin and digoxin are among the most commonly prescribed forms of digitalis.

diglossia, the coexistence of two forms of the same language in a speech community. Often, one form is the literary or prestige dialect, and the other is a common dialect spoken by most of the population. Such a situation exists in many speech communities throughout the world—*e.g.*, in Greece, where Katharevousa, heavily influenced by Classical Greek, is the prestige dialect and Demotic is the popular spoken language, and in Egypt, where there are two dialects of Arabic. Sociolinguists may also use the term diglossia to denote bilingualism, the speaking of two or more languages by the members of the same community, as, for example, in New York City, where many members of the Hispanic community speak both Spanish and English, switching from one to the other according to the social situation or the needs of the moment.

Digne-les-Bains, town, capital of Alpes-de-Haute-Provence *département*, Provence-Alpes-Côtes-d'Azur *région*, southeastern France. It lies 83 miles (134 km) northwest of Cannes by road. Situated on the scenic Route Napoléon, along which Napoleon traveled over the Alps on his return from Elba in 1815, it is a centre for tourism. It lies on the east (left) bank of the Bléone River, a tributary of the Durance. Digne-les-Bains has been an episcopal see since at least the 6th century. Local cultivation of lavender and fruits for preserving has made the town known all over France. Pop. (1990) 17,425.

Digul River, Dutch DIGOEL RIVIER, river rising on the southern slopes of the Sterren Mountains in east-central Irian Jaya, Indonesia, on the island of New Guinea. The river flows 326 miles (525 km) south and west across a low region of extensive swamps (in the rainy season) to empty into the Arafura Sea immediately north of Dolak (Frederik Hendrik) Island. The river is navigable as far as Tanahmerah.

Dijon, city, capital of Côte d'Or *département* and of Bourgogne (Burgundy) *région*, east-central France. The city is 203 miles (326 km) southeast of Paris by road and lies at the confluence of the Ouche and Suzon rivers. Situated at the foot of the Côte d'Or hills to its west and near a plain of fertile vineyards, the city has many outstanding old buildings, some dating back to the 15th century. It has always been a regional transportation hub and was known in the 9th century as *Castrum Divionense*. In 1015 Robert I, Duke of Burgundy, chose it as the capital for his newly founded duchy, but only with the second ducal dynasty—that of Valois (1364–1477)—did the city flourish. Musicians, artists, and architects were attracted there by the patronage of the ducal court. The city retained its importance as a provincial capital after the duchy of Burgundy had been annexed by Louis XI of France in 1477, and the Burgundy Parliament sat there regularly. Dijon was most prosperous in the 18th century, when it was also an intellectual centre of France. The city declined after the French Revolution, when its provincial institutions were suppressed, but the coming of the railways in 1851 brought it new wealth and population growth.

Dijon is still a major communications centre as well as a market and tourist town. A large number of industries, including foundries, automobile plants, and mechanical and electrical works have developed in the area. Celebrated Dijon food products are mustard, vinegar, and

gingerbread; chocolate and liqueurs are also made. The University of Dijon was founded in 1722. The city has been a diocese since 1731.

The buildings of the palace of the dukes of Burgundy are located in the centre of the old city. The original medieval palace was largely rebuilt and extended in the 17th and 18th centuries. Only two towers—the guardroom and the kitchens—survive from the original 14th- and 15th-century building. The palace is now the *hôtel de ville* (town hall) and contains the Musée des Beaux Arts. The magnificent tombs of Philip the Bold (1342–1404) and John the Fearless (1371–1419), dukes of Burgundy, are found there. A psychiatric hospital now stands on the site of the Chartreuse de Champmol, a Carthusian monastery founded by Philip the Bold in 1383, but the doorway of the chapel and other fine vestiges survive from the original building. In the west of the old city stands the Cathedral of Saint-Bénigne, an example of pure Burgundian Gothic built in the early 14th century. The Church of Saint-Philibert, close by, now deconsecrated, has a 12th-century nave. The Gothic Church of Notre-Dame (early 13th century) has an original facade with magnificent carvings around its triple doorway. The later Renaissance facade (1661) of the Church of Saint-Michel (1529) also has a fine sculptured doorway. Pop. (1990) 151,636.

dik-dik (genus *Madoqua*), any of several small, delicate African antelopes, family Bovidae (order Artiodactyla), named for the sound it makes when alarmed. The dik-dik stands 30–40 cm (12–16 inches) at the shoulder and weighs 3–5 kg (7–11 pounds). It has an elongated snout and a soft coat that is gray or

Dik-dik (*Madoqua*)
Jack Cannon—Ostman Agency

brownish above, white below. The hair on the crown forms an upright tuft and may partially conceal the short, ringed horns of the male. The four species of dik-diks inhabit dry areas of dense brush in southern and eastern Africa. They feed chiefly on acacias and other shrubs.

dika nut, edible nut of the dika tree, which is also called the dika bread, or Gabon chocolate, tree (species *Irvingia barteri*), and is native to western Africa. The nut is used principally for food and oil.

The fruit of the dika is a large edible drupe with thick, fibrous flesh. The kernels are taken from the stones and roasted like coffee beans, then pounded and poured into a mold before being added to boiling meat and vegetables. The kernels are also used to adulterate chocolate and ground to make flour. The fat is

extracted from the seeds for soap and candle-making. A relish made from the dika nut is customarily eaten with plantain.

dike, in geology, tabular or sheetlike igneous body that is often oriented vertically or steeply inclined to the bedding of preexisting intruded rocks; similar bodies oriented parallel to the bedding of the enclosing rocks are called sills. A dike set is composed of several parallel dikes; when the number of dikes is large, the term dike swarm is used. Although dikes may range in size from a fraction of an inch to dozens of feet in width, they average between 1 and 20 feet wide. The length of a dike usually depends upon how far it can be traced across the surface; dikes can be up to hundreds of miles long. Dikes have a wide range of rock compositions. They commonly have a porphyritic texture, *i.e.*, larger crystals within a finer grained groundmass, indicating two periods of crystallization.

Dikelocephalus, genus of trilobites (extinct arthropods) that is a useful guide fossil for the Late Cambrian rocks (523 to 505 million years ago) of Europe and North America. *Dikelocephalus* is distinguished by its broad head, its large and relatively well-developed tail, and its pair of short spines at the end of the tail. The eyes of *Dikelocephalus* are large and crescentic in shape.

Dikran II THE GREAT: *see* Tigranes II the Great.

dikṣā, rite of consecration that preceded the Vedic sacrifice in ancient India; in later and modern Hinduism, the initiation of a layman by his guru (spiritual guide) into a sect.

In the soma sacrifices of the Vedic period, the lay sacrificer, after bathing, kept a daylong (in some cases up to a yearlong) silent vigil inside a special hut in front of a fire. He was dressed in garments of black antelope skin, which he also used to sit on, and at nightfall drank only cooked milk. The *tapas* (a mystical condition that was a basis of all Indian ascetic practices) produced was considered to be a sign, and a means, of passing from the realm of the profane to that of the sacred. Like similar rites observed throughout the world, *dikṣā* also carried with it the meaning of a "rebirth," and the scriptures describing the ceremony made use of explicit symbolism, such as the "womb" of the hut.

At the end of the soma ritual, the sacrificer went through a reverse ceremony, the *avabhṛtha* ("concluding bath"), in which he again bathed, and his sacred garments, the ritual utensils, and the pressed shoots of the soma plant were all cast into the water.

In modern Hinduism, rites of consecration and initiation show many regional and sectarian variations. They are generally preceded by preparatory fasting, bathing, and dressing in new clothes and include in the act of initiation the placing of special marks on the body or forehead, taking on a new name, receiving from the preceptor a selected mantra (prayer formula), and worship.

Dikwa, also called DIKOA, town and traditional emirate, Borno state, Nigeria. The town lies near the Yedseram River, which flows into Lake Chad, and has road connections to Maiduguri, Bama, Ngala, and Kukawa. Precisely when the town was founded and when its walls (30 feet [9 m] thick) were built is unknown; but it had certainly become a major centre of the Borno kingdom (*see* Kanem-Bornu) of the Kanuri people by the 1850s.

In 1893, after the Sudanese warrior Rābiḥ az-Zubayr (Rabah Zubayr) conquered almost all of Borno, Dikwa was selected by Rābiḥ to be the new Borno capital and seat of the *shehu* (sheikh). Although Rābiḥ was killed by the French in 1900, and the immediate region

came under French control, Dikwa remained the *shehu's* seat until 1902. Dikwa was occupied by the British during World War I, and in 1922 Dikwa emirate became part of the League of Nations mandate of British Cameroons. In 1942 the emirate headquarters was moved from Dikwa town to Bama, 40 miles (64 km) south-southwest.

Although administered by Nigeria's Borno province during British rule, the emirate became part of the United Nations trust territory of Northern Cameroons in 1946. After rejecting union with Nigeria in 1959, its peoples, mostly Kanuri and Shuwa Arab peoples, voted to join a new (later Saradauna) province in Northern Nigeria in the 1961 plebiscite. A year later, however, they were able to secede from Saradauna and unite with their kinsmen in Borno province. Dikwa was part of North-Eastern state from 1967 to 1976.

Most of the area's population is engaged in herding (especially cattle) and in farming (chiefly cotton, peanuts [groundnuts], millet, sorghum, corn [maize], and indigo). Fishing is important, both along the shores of Lake Chad and the Yedseram. Cotton weaving and dyeing are significant local activities, as is the tanning of leather. The Shuwa also use their cattle—a practice unusual in Nigeria—to transport goods and people.

Dikwa town has a government health office and a dispensary; but Bama, besides being the seat of the emirate, is larger, has more medical and educational facilities, and is a trade centre. Pop. (latest est.) town, 10,860.

Dilas, Milovan: *see* Djilas, Milovan.

dilator muscle, any of the muscles that widen a body part—*e.g.*, in humans, the dilator pupillae, fibres that extend radially through the iris of the eye and contract as available light decreases, thus dilating the pupil. There is also a dilator naris, which aids in widening the nostrils. *Compare* sphincter muscle.

dilemma, in syllogistic, or traditional, logic, any one of several forms of inference in which there are two major premises of hypothetical form and a disjunctive ("either . . . or") minor premise. For example:

If we increase the price, sales will slump.

If we decrease the quality, sales will slump.

Either we increase the price or

we decrease the quality.

Therefore, sales will slump.

In logic \supset signifies "if . . . then"; \vee signifies "either . . . or". Symbolically, therefore, a dilemma is an argument of the form $A \supset C$, $B \supset C$, $A \vee B$, therefore C .

It is not necessary that a dilemma should have an unwelcome conclusion; but from its use in rhetoric the word has come to mean a situation in which each of the alternative courses of action (presented as the only ones open) leads to some unsatisfactory consequence. To take a familiar example, a person who is asked, "Have you stopped beating your wife?" is presented with a rhetorical dilemma. In this more complicated version of the dilemma, however, two unwelcome results are presented instead of one (C , above). Thus, the conclusion itself becomes a disjunction:

Either you have been beating your wife or you are continuing to beat her.

dilemma tale, also called JUDGMENT TALE, typically African form of short story whose ending is either open to conjecture or is morally ambiguous, thus allowing the audience to comment or speculate upon the correct solution to the problem posed in the tale. Typical issues raised involve conflicts of loyalty, the necessity to choose a just response to a difficult situation, and the question of where to lay the blame when several parties seem equally guilty. An example is the story of a young boy who in a time of crisis must choose between loyalty to his own father, who is a cruel and

unjust man, and loyalty to the kindly foster-father who brought him up.

Another tale deals with a man who died while hunting an ox to feed his three wives. The first wife learns through a dream what has happened to him, the second leads her fellow wives to the place where he died, and the third restores him to life. Which of the three most deserves his praise?

A third tale has a tortoise as central character. Tortoise wishes to be thought of as equal in power and authority to Hippopotamus and Elephant. When his boasts reach their ears, however, they snub him by saying he is only a small being of no account. So Tortoise challenges both of them to a tug of war and through a trick pits them against each other, thus winning from each the grudging consent that he is their equal. The audience must decide exactly how equal the three of them are.

A final example is the tale of three brothers, all married to the same girl, who journey together to a strange land. One night the girl is murdered by a robber, and the eldest brother, with whom she is sleeping, is condemned to death on suspicion. He begs leave to visit his father before he dies. When he is late in returning, the second brother offers to die in his place, but, as he is about to be executed, the third brother steps forward and "confesses" that he is the murderer. At that moment the eldest brother rides in, just in time to embrace his fate. Which of the brothers, the listeners are asked, is the most noble? As these four examples show, dilemma tales function both as instruction and entertainment, and they help to establish social norms for the audience.

Dili, also spelled DILLY, or DILLI, city and administrative centre of East Timor territory. It lies on Ombai Strait on the northern coast of Timor island, the easternmost of the Lesser Sunda Islands. Dili is the chief port and commercial centre for East Timor; it also has an airport. The population is mostly Timorese and Atonese with minorities of Portuguese, Eurasians, and Arab Muslims.

Dili was settled about 1520 by the Portuguese, who made it an administrative centre; Spanish, Dutch, and British forces also vied for control of the colony. During World War II it was occupied by the Japanese. In 1975 East Timor achieved independence from Portugal, but Indonesian forces invaded and, in 1976, designated Dili the capital of East Timor (Timor Timur) *propinsi* (province). However, a brutal guerrilla war ensued between Indonesian and pro-independence forces, during which thousands of civilians were killed. In 1999 the territory was placed under UN supervision. Pop. (1999 est.) 65,000.

diligence, large, four-wheeled, closed French stagecoach employed for long journeys. It was also used in England and was popular in both countries in the 18th and 19th centuries.

Diligences, some of which held up to 16 people, were divided into two or three compartments. The driver rode on a seat directly above the front wheels, on the same level as, but unattached to, the coach body, on a seat

Model of a diligence; in the Carnavalet Museum, Paris
J.E. Bulloz

on the body, or postilion. A famous diligence line operated between Paris and Lyon.

Dilke, Sir Charles Wentworth, 2ND BARONET (b. Sept. 4, 1843, London, Eng.—d. Jan. 26, 1911, London), British statesman and Radical member of Parliament who became a member of the Cabinet in William E. Gladstone's second administration but was ruined at the height of his career when he was cited as correspondent in a divorce suit.

After leaving the University of Cambridge and making a world tour, Dilke was elected to Parliament in 1868 and took an extreme left-wing position, delivering a series of speeches strongly critical of the monarchy. From 1874 on, however, with the Liberals in opposition, he moved closer to his official leaders. In Gladstone's second Liberal government, Dilke was finally promoted to the Cabinet as president of the Local Government Board in 1882.

Apart from his departmental activities, Dilke was eager, with Joseph Chamberlain, to press the general Radical point of view within the Cabinet. This eagerness led him to submit frequent resignations to Gladstone. It also led him to a position of great political promise. By the end of the government, in June 1885, Benjamin Disraeli's prophecy of 1879 that Dilke would be prime minister looked plausible.

The issue was never put to the test, for, a month later, Dilke was cited as correspondent in a sensational divorce suit. Virginia Crawford, the 22-year-old wife of a Scottish Liberal lawyer, told her husband that she had been Dilke's mistress since 1882. Dilke strenuously denied the story, and, when the case was heard, in February 1886, there was adjudged to be no evidence against him, although Crawford got his divorce. A press campaign, in which the *Pall Mall Gazette* took the lead, made this an inadequate victory for Dilke. To try to clear his name he got the queen's proctor to reopen the case, and a second hearing took place in July 1886. This went heavily against Dilke. One of his public difficulties was that, although he rebutted Mrs. Crawford's allegations, he was forced to admit to having been her mother's lover.

Six years later, Dilke returned to the House of Commons and held the seat until his death. He was active in the Commons as a military expert and as an exponent of advanced labour legislation. Much of his energy, however, was devoted to gathering evidence that might clear his name. The accumulated evidence showed decisively that much of Mrs. Crawford's story was a fabrication; whether there was a substratum of truth remains uncertain.

dill (species *Anethum graveolens*), fennel-like annual or biennial herb of the parsley family (Apiaceae, or Umbelliferae) or its dried, ripe fruit, or seeds, and leafy tops; these are used to season foods, particularly in eastern Europe and Scandinavia. Native to Mediterranean countries and southeastern Europe, dill is now widely cultivated in Europe, India, and North America. The entire plant is aromatic, and the small stems and immature umbels are used for flavouring soups, salads, sauces, fish,

sandwich fillings, and particularly pickles. Dill has a warm, slightly sharp flavour somewhat reminiscent of caraway. The whole seeds and the seed oil have carminative properties and have been used in treating flatulent colic.

The fruit, or seed, is broadly oval in shape, about 0.14 inch (3.5 mm) long, with three longitudinal dorsal ridges and two winking lateral ridges. It is light brown in colour. The essential oil content is about 3 percent; its principal component is carvone.

Dill, Sir John Greer (b. Dec. 25, 1881, Lurgan, County Armagh, Ire.—d. Nov. 4, 1944, Washington, D.C., U.S.), British field marshal who became the British chief of staff during the early part of World War II and, from 1941 to 1944, headed the British joint staff mission to the United States.

After serving in the South African War (1899–1902) and in World War I, Dill advanced steadily, becoming director of military operations and intelligence at the War Office in 1934; he was knighted in 1937. Recognized

Dill
Camera Press

as Britain's foremost strategist, he was head of a corps in France at the beginning of World War II, becoming chief of the imperial general staff in May 1940. He was largely responsible for the decision to reinforce Egypt with 150 tanks in August in spite of the shortage at home and backed Britain's intervention in Greece (March 1941). His greatest service to the Allied war effort, however, was as chief British military representative to Washington, D.C. (1941–44), where he helped coordinate the military policies of the two major western Allies. His friendship with the U.S. chief of staff, George C. Marshall, did much to cement Anglo-U.S. solidarity.

Dilleniaceae, order of dicotyledonous flowering plants comprising two families (Dilleniaceae and Paeniaceae), with 11 genera, most of which are trees, shrubs, or woody vines of the tropics and subtropics. The plants are characterized by radially symmetrical, usually bisexual flowers with three to many (but usually five) overlapping sepals; usually five overlapping petals; numerous stamens (the male pollen-producing structures); and several separate, ovule-bearing structures (pistils), each containing an indefinitely large number of ovules that develop into seeds with a fleshy appendage (aril) attached. Each pistil is topped by a slender pollen-receptive structure (the style). The flower has a characteristic appearance from the spreading of the styles.

The order is botanically significant as an evolutionary link between the more primitive magnolia order (Magnoliales) and several more advanced orders, the most immediately related of which are the tea or camellia order (Theales) and the violet order (Violales).

The Dilleniaceae has a few tree species that

are useful for their timber (e.g., *Dillenia indica*, *D. parviflora*, and *D. pentagyna*) and as a source of tannin. Several species of *Hibbertia* are grown as ornamentals, especially *H. scandens*, a woody vine with yellow, ill-smelling flowers, which is grown only in warm areas such as southern California or in greenhouses. *Dillenia indica* is also a greenhouse plant in temperate areas, where it is grown for its fragrant white flowers. It is a tree in its native area (Southeast Asia to Australia and Fiji), however, where it is valued for its lemon-flavoured fruits used in jellies and curries.

The largest genera of the family Dilleniaceae are *Hibbertia* (100 species), *Dillenia* (60 species), *Tetracera* (40 species), *Doliocarpus* (40 species), and *Davilla* (38 species).

The family Paeniaceae contains only the genus *Paonia*, which has 30 species of small-leaved perennial herbs or shrubs of temperate Europe and Asia, with one or two species in the western United States.

Dilleniidae, subclass of woody or herbaceous dicotyledonous flowering plants.

A brief treatment of the Dilleniidae follows. For full treatment, see MACROPAEDIA: Angiosperms.

The flowers of plants belonging to the Dilleniidae usually contain numerous petals, stamens, and staminodes. The carpels of the gynoecium are united in a compound ovary, which often rises above the floral envelope. The subclass Dilleniidae consists of 13 orders, of which the majority of species are contained in the orders Violales, Capparales, Ericales, Theales, Malvales, Primulales, and Ebenales. The remaining six orders within the Dilleniidae, together constituting less than one-fourth of the species in it, are Nepenthales, Lecythidales, Salicales, Batales, Diapensiales, and Dilleniaceae.

Dillenius, Johann Jakob (b. 1687, Darmstadt, Hesse-Darmstadt [Germany]—d. April 2, 1747, Oxford, Oxfordshire, Eng.), botanist who wrote several descriptive works on plants.

His *Catalogus Plantarum circa Gissam sponte nascentium* (1718; "Catalog of Plants Originating Naturally Around Giessen") treated 980 species of higher plants, 200 mosses and related forms, and 160 fungi found near Giessen, where he attended the university. In August 1721 he went to England, where in 1728 he became the first professor of botany at Oxford University. There he produced his most notable works, *Hortus Elthamensis*, 2 vol. (1732), which contains descriptions and 417 drawings of plants in the Sherard Garden at Eltham, and *Historia Muscorum* (1741), which contains descriptions and illustrations of more than 600 species of "mosses," an assemblage of true mosses, liverworts, lycophytes, algae, lichens, and other lower plants. The Swedish naturalist Linnaeus, who visited Dillenius in 1735, dedicated his own *Critica*

Dillenius, detail from an engraving by James Heath after an original portrait by an unknown artist

Dill (*Anethum graveolens*)
Ingmar Holmsten

Botanica to him and later named the flowering-plant genus *Dillenia* in his honour.

Dilli (Indonesia): see Dili.

Dillinger, John (Herbert) (b. June 28, 1902, or June 22, 1903, Indianapolis, Ind., U.S.—d. July 22, 1934, Chicago), most famous of all U.S. bank robbers, whose short career of robberies and escapes from June 1933 to July 1934 won media headlines.

Born in Indianapolis but spending his adolescence on a farm in nearby Mooresville, Dillinger joined the Navy in 1923, serving on the USS "Utah" but deserting after only a few months. In September 1924, caught in the foiled holdup of a Mooresville grocer, he served the next several years (1924–33) in Indiana state prisons. While in prison, he learned the craft of bank robbery from tough professionals and, upon parole on May 22, 1933, turned his knowledge to profit, taking (with one to four confederates) five Indiana and Ohio banks in four months and gaining his first notoriety as a daring, leaping, sharply dressed gunman.

Captured and jailed in Ohio in September, he was rescued by five former convict pals whose own escape from Indiana State Prison he had earlier financed and plotted. Dillinger and his gang next robbed banks in Indiana and Wisconsin and fled south to Florida and then to Tucson, Ariz., where they were discovered and arrested by local police. Dillinger was extradited to Indiana and lodged in the Crown Point, Ind., jail, where on March 3, 1934, he executed his most celebrated escape. With a razor and a piece of wood, he carved a fake pistol, blackened it with bootblack, and used it to force his way past a dozen guards to freedom, singing as he left, "I'm heading for the last roundup."

There followed more bank robberies with new confederates; Dillinger twice barely escaped FBI entrapments and shootouts in Minnesota and Wisconsin. His end came through a trap set up by the FBI, Indiana police, and one Anna Sage, a friend and brothel madam. This well-publicized "lady in red" drew Dillinger to the Biograph Theatre in Chicago, where, on emerging, he was shot to death.

Some researchers have claimed that another man, not Dillinger, was killed outside the Biograph and that Dillinger's allies accomplished a hoax on the FBI, leaving him free to disappear.

Dillon (eastern South Island, New Zealand): see Waiiau River.

Dillon, city, seat of Beaverhead county, southwestern Montana, U.S., on the Beaverhead River (part of the Jefferson River system). It was founded as Terminus in 1880 with the arrival of the Utah and Northern Railroad and was renamed (1881) for Sidney Dillon, president of the Union Pacific, who directed completion of the line to Butte, 55 mi (89 km) north. The community (incorporated in 1885) developed as a wool-shipping point, and the founding there in 1893 of Montana's first normal school (later Western Montana College) sustained its growth. The city lies between divisions of the Beaverhead National Forest, for which it is headquarters, in an area of old mining camps (reflected in the Beaverhead County Museum). Nearby Bannack, now a ghost town and site of Montana's first major gold strike (1862), was once a bustling community of 8,000 and the first territorial capital. Dillon's economy now depends on ranching and farming (livestock, hay, and seed potatoes), mining, and tourism. Dude ranches dot the surrounding countryside. The Maverick Ski Area is to the northwest and, Clark Canyon Reservoir State Recreation Area is 20 mi south. Pop. (1990) 3,991.

Dillon, John (b. Sept. 4, 1851, Blackrock, County Dublin, Ire.—d. Aug. 4, 1927, London), a leader of the Irish Nationalist Party in the struggle to secure Home Rule by parliamentary means. Through the 1880s he was perhaps the most important ally of the greatest 19th-century Irish Nationalist, Charles Stewart Parnell; but after Parnell's involvement in a divorce case, Dillon repudiated him for reasons of political prudence.

John Dillon, 1890
By courtesy of Myles Dillon

The son of the Irish patriot John Blake Dillon (1816–66), John Dillon was a member of the British House of Commons, 1880–83 and 1885–1918. For his vigorous work in the Irish Land League, which sought fixed tenure, fair rents, and free sale of Irish land, he was imprisoned twice between May 1881 and May 1882 and was Parnell's fellow inmate of Kilmainham jail, Dublin, from October 1881. For six months in 1888 he was imprisoned for aiding William O'Brien, author of the "plan of campaign" against high rent charges by English absentee landlords in Irish farming districts.

When Parnell was named co-respondent in Capt. William Henry O'Shea's divorce suit in 1890, Dillon and O'Brien at first affirmed their support of him, but they finally decided that he would thenceforth be a liability as party leader. The party then split, the anti-Parnellite majority forming the Irish Nationalist Federation, of which Dillon served as chairman from 1896. In 1900, however, he agreed to join a reunited party under the Parnellite John Redmond.

During the prime ministry (1902–05) of Arthur James Balfour, Dillon came to believe that the British Conservative government intended to grant Irish reforms without independence, thereby "killing Home Rule by kindness." In 1905 he advised Irishmen to vote for Liberal Party candidates for Parliament, and, after the Liberals had taken office that year, he supported their reform program. Throughout World War I he vehemently opposed the extension of British military conscription to Ireland, both because that measure would strengthen the agitation by the more extreme nationalist Sinn Féin (We Ourselves) Party and because he never accepted the view that British imperial interests necessarily coincided with those of Ireland. After the Easter Rising in Dublin in 1916, Dillon protested against the harsh measures that ensued and, in the House of Commons, made a passionate speech in defense of the Irish rebels.

On Redmond's death (March 6, 1918), Dillon, who had broken with him over the Irish war effort, succeeded him as Nationalist Party leader. By that time, however, the party had been discredited, and in the election of December 1918 Sinn Féin won easily. On losing his House of Commons seat to Eamon De Valera (afterward president of the Republic of Ireland), Dillon retired from politics.

Dilly (Indonesia): see Dili.

Dilmun, Sumerian name of an ancient independent kingdom that flourished c. 2000 BC,

plausibly identified with the island in the Persian Gulf now called al-Bahrain. Dilmun is mentioned as a commercial centre in Sumerian economic texts of the 3rd millennium BC, when it was a transshipment point for goods between Sumer and the Indus Valley. Copper and a variety of other goods, including stone beads, precious stones, pearls, dates, and vegetables, were shipped to Sumer and Babylonia in return for agricultural products.

Bārbār, the remains of an ancient temple (largely built of limestone) situated on al-Bahrain, and many thousands of burial mounds attest to the island's prominence. Qala'at (fort) al-Bahrain, a large low tell covering about 45 ac (18 ha) on the northern coast of the island, is the largest site and consists of a city dating from about 2800 BC that had seven major building phases including, in its second phase (2300–1800 BC), city walls; other artifacts found dating to this phase are chert weights of the Indus Valley type, distinctive round steatite stamp seals, and quantities of copper. Related archaeological sites have been found on the northern coast of the Arabian Peninsula and on other offshore islands in the Persian Gulf.

Dilthey, Wilhelm (b. Nov. 19, 1833, Biebrich, near Wiesbaden, Nassau—d. Oct.

Dilthey, detail of an oil painting by R. Lepsius, c. 1904; in a private collection
Archiv für Kunst und Geschichte, West Berlin

1, 1911, Seis am Schlern, near Bozen, South Tirol, Austria-Hungary). German philosopher who made important contributions to a methodology of the humanities and other human sciences. He objected to the pervasive influence of the natural sciences and developed a philosophy of life that perceived man in his historical contingency and changeability. Dilthey established a comprehensive treatment of history from the cultural viewpoint that has been of great consequence, particularly to the study of literature.

Dilthey was the son of a Reformed Church theologian. After he finished grammar school in Wiesbaden, he began to study theology, first at Heidelberg, then at Berlin, where he soon transferred to philosophy. After completing exams in theology and philosophy, he taught for some time at secondary schools in Berlin but soon abandoned this to dedicate himself fully to scholarly endeavours.

During these years he was bursting with energy, and his investigations led him into diverse directions. In addition to extensive studies on the history of early Christianity and on the history of philosophy and literature, he had a strong interest in music, and he was eager to absorb everything that was being discovered in the unfolding empirical sciences of man: sociology and ethnology, psychology and physiology. Hundreds of reviews and essays testify to an almost inexhaustible productivity.

In 1864 he took his doctorate at Berlin and obtained the right to lecture. He was appointed to a chair at the University of Basel in 1866; appointments to Kiel, in 1868, and Breslau, in 1871, followed. In 1882 he succeeded R.H.

Lotze at the University of Berlin, where he spent the remainder of his life.

During these years Dilthey led the quiet life of a scholar. He searched for the philosophical foundation of what he first and rather vaguely summarized as the "sciences of man, of society, and the state," which he later called *Geisteswissenschaften* ("human sciences")—a term that eventually gained general recognition to collectively denote the fields of history, philosophy, religion, psychology, art, literature, law, politics, and economics. In 1883, as a result of these studies, the first volume of his *Einleitung in die Geisteswissenschaften* ("Introduction to Human Sciences") appeared. The second volume, on which he worked continually, never did appear. This introductory work yielded a series of important essays; one of these—his "Ideen über eine beschreibende und zergliedernde Psychologie" (1894; "Ideas Concerning a Descriptive and Analytical Psychology")—instigated the formation of a cognitive (*Verstehen*), or structural, psychology. During the last years of his life, Dilthey resumed this work on a new level in his treatise *Der Aufbau der geschichtlichen Welt in den Geisteswissenschaften* (1910; "The Structure of the Historical World in the Human Sciences"), which was also left unfinished.

Opposed to the trend in the historical and social sciences to approximate the methodological ideal of the natural sciences, Dilthey tried to establish the humanities as interpretative sciences in their own right. In the course of this work he broke new philosophical ground by his study of the relations between personal experience, its realization in creative expression, and the reflective understanding of this experience; the interdependence of self-knowledge and knowledge of other persons; and, finally, the logical development from these to the understanding of social groups and historical processes. The subject matter of the historical and social sciences is the human mind, not as it is enjoyed in immediate experience nor as it is analyzed in psychological theory, but as it manifests or "objectifies" itself in languages and literatures, actions, and institutions. Dilthey emphasized that the essence of human beings cannot be grasped by introspection but only from a knowledge of all of history; this understanding, however, can never be final because history itself never is: "The prototype 'man' disintegrates during the process of history." For this reason, his philosophical works were closely connected to his historical studies. From these works later arose the encompassing scheme of his *Studien zur Geschichte des deutschen Geistes* ("Studies Concerning the History of the German Mind"); the notes for this work make up a complete coherent manuscript, but only parts have been published.

Dilthey held that historical consciousness—i.e., the consciousness of the historical relativity of all ideas, attitudes, and institutions—is the most characteristic and challenging fact in the intellectual life of the modern world. It shakes all belief in absolute principles, but it thereby sets people free to understand and appreciate all the diverse possibilities of human experience. Dilthey did not have the ability for definitive formulation; he was suspicious of rationally constructed systems and preferred to leave questions unsettled, realizing that they involved complexity. For a long time, therefore, he was regarded primarily as a sensitive cultural historian who lacked the power of systematic thought. Only posthumously, through the editorial and interpretative work of his disciples, did the significance of the methodology of his historical philosophy of life emerge.

(O.F.B./Ed.)

BIBLIOGRAPHY. Dilthey's works are collected in *Gesammelte Schriften* (1914–). Works on Dilthey in English include H.A. Hodges, *Wilhelm Dilthey: An Introduction* (1944, reissued 1969), with translations of selected excerpts; Rudolf A. Makkreel,

Dilthey: Philosopher of the Human Studies (1975, reissued 1992); Michael Ermarth, *Wilhelm Dilthey: The Critique of Historical Reason* (1978); H.P. Rickman, *Wilhelm Dilthey: Pioneer of the Human Studies* (1979), and *Dilthey Today: A Critical Appraisal of the Contemporary Relevance of His Work* (1988); and Theodore Plantinga, *Historical Understanding in the Thought of Wilhelm Dilthey* (1980, reissued 1992).

DiMaggio, Joe, byname of JOSEPH PAUL DIMAGGIO, also called JOLTIN' JOE or the YANKEE CLIPPER (b. Nov. 25, 1914, Martinez, Calif., U.S.—d. March 8, 1999, Hollywood, Fla.), American professional baseball player who was an outstanding hitter and fielder and one of the best all-round players in the history of the game.

DiMaggio
EB Inc

DiMaggio was the son of Italian immigrants who made their living by fishing. He quit school at 14 and at 17 began playing baseball with the minor league San Francisco Seals. DiMaggio's contract with San Francisco was purchased by the New York Yankees, and he was brought up to the major leagues in 1936. In his rookie season with the Yankees he batted .323 during the regular season and .346 against the N.Y. Giants in the World Series.

In 1937 DiMaggio led the American League in home runs and runs scored, and in 1939 and 1940 he led the American League in batting, with averages of .381 and .352. DiMaggio's consistency as a hitter led to his setting one of the most remarkable records of major league baseball—hitting safely in 56 consecutive games (May 15–July 16, 1941). In addition to his fine hitting ability, DiMaggio had outstanding skill as a fielder, tying the American League fielding record in 1947 with only one error in 141 games.

Between 1936 and 1951 DiMaggio helped the Yankees to nine World Series titles—in 1936, 1937, 1938, 1939, 1941, 1947, 1949, 1950, and 1951. During the same period the Yankees won 10 American League championships (the Yankees won the pennant but not the World Series in 1942). DiMaggio missed three seasons (1943 through 1945) serving in the military during World War II.

DiMaggio received the Most Valuable Player Award for the American League in 1939, 1941, and 1947. He retired at the end of the 1951 season. He was elected to the Baseball Hall of Fame in 1955.

In 1954 DiMaggio married film star Marilyn Monroe—this only added to his iconic status in American culture. Though this marriage lasted less than a year, the couple remained close until her death in 1962. In his retirement he acted as a spokesman for commercial concerns and worked for charitable causes.

Dimbleby, Richard, in full RICHARD FREDERICK DIMBLEBY (b. May 25, 1913, Richmond, Surrey, Eng.—d. Dec. 22, 1965, London), pioneer radio news reporter and the first of Britain's great broadcast journalists. He was the first war correspondent for the British Broadcasting Corporation (BBC); his voice became familiar to most Britons via radio, and

early in the television era his imposing visual presence became equally well known.

Dimbleby was the son of an editor and statesman, Frederick J.G. Dimbleby. Richard worked on the newspaper owned by his family, the *Richmond and Twickenham Times*, after graduating from secondary school. Five years later, after working for several other newspapers, he persuaded the BBC to engage him in its Topical Talks Department (1936). He was a self-assured, articulate young man, and he soon found his way into an assignment that only later acquired a name: radio news reporter. He was, in fact, one of the inventors of broadcast journalism, and as he felt his way in that new craft, he created traditions that would guide the future course of radio and, later, television reporting.

The BBC did not have a foreign correspondent until it sent Dimbleby to Spain to cover the Civil War. It created the title "war correspondent" for him at the outbreak of World War II, and he covered the war on the ground in Europe, Africa, and the Middle East, and in the air with the Royal Air Force over Germany.

During his coverage of World War II Dimbleby wrote several books; throughout his television heyday he contributed frequently to radio programs; and he never ceased a drumfire of correspondence in newspapers and journals—all the while maintaining an active involvement in the management of the family newspaper where his career had begun.

Two of Dimbleby's children, David and Jonathan, also became television journalists of distinction. Richard Dimbleby's memory is perpetuated by the Dimbleby Awards for distinguished contributions by broadcast journalists to their profession.

Dimbokro, town, south-central Côte d'Ivoire (Ivory Coast). It lies along the Nzi River, which is a tributary of the Bandama River. A local trade centre (yams, bananas, and palm oil and kernels) among the Baule (Baoule) people, it has been a major entrepôt for cocoa, coffee, yams, kola nuts, and kapok since the completion of the central railway from Abidjan, 103 miles (166 km) south-southeast, in 1910. A textile factory was established in the town in the 1970s. Pop. (1988) 38,183.

dimension, in geometry, a magnitude measured in a specific direction, as, for example, along a diameter or a principal axis or an edge. A point is said to be without dimension; a line has the one dimension of length, a surface has the two dimensions of length and breadth, while a solid has the three dimensions of length, breadth, and thickness. Since the lengths of lines, the areas of surfaces, and the volumes of solids are represented respectively by linear, quadratic, and cubic algebraic expressions, the term dimension has been carried over into algebra. Thus quadratic, cubic, and biquadratic algebraic expressions (e.g., x^2 , x^3 , x^4) or equations are said to be respectively of two, three, and four dimensions (or degree or order). Similarly, the term dimension is used in mechanics with reference to the units of time, length, and mass and various derived units, and it occurs in many other parts of physics, notably in the theory of electricity and magnetism.

dimensional analysis, technique used in the physical sciences and engineering to reduce physical properties such as acceleration, viscosity, energy, and others to their fundamental dimensions of length (L), mass (M), and time (T). This technique facilitates the study of interrelationships of systems (or models of systems) and their properties and avoids the nuisance of incompatible units. Acceleration, for example, is expressed as L/T^2 in dimensional analysis because it is a distance (L,

length) per unit of time (T) squared; whether the actual units of length are expressed in the English or metric system is immaterial. Dimensional analysis is often the basis of mathematical models of real situations. If model results are to be translatable in terms of the system being modeled, then the model must be dimensionally faithful to the original. *See also* mathematical model.

dimercaprol, also called BRITISH ANTI-LEWISITE (BAL), drug that was originally developed to combat the effects of the blister gas lewisite, which was used in chemical warfare. By the end of World War II, dimercaprol had also been found useful as an antidote against poisoning by several metals and semimetals—including arsenic, gold, lead, and mercury—that act by combining with cellular sulfhydryl groups. Dimercaprol is more effective if its use is begun within two hours after ingestion of the toxic metal. Because of its instability in water, it is administered by intramuscular injection of a solution of it in peanut oil.

dimethoate, any systemic insecticide that acts by inhibiting cholinesterases, enzymes involved in transmitting nerve impulses. Chemically, it is an organophosphate. Like all organophosphates it is related to the nerve gases and is among the most toxic of all pesticides to vertebrates, including humans. As a systemic, dimethoate is taken up into the roots of plants and translocated to aboveground parts, where it is toxic to any sucking insect feeding on the plant juices (e.g., aphids, leafhoppers, and thrips). Caterpillars and other chewing pests are not killed by dimethoate because not enough juice-containing tissue is ingested to be effective.

dimethyl sulfoxide, simplest member of the sulfoxide family of organic compounds; *see* sulfoxide.

dimethylaminoethylbenzamide: *see* phenbenzamine.

dimethyltryptamine (hallucinogenic drug): *see* DMT.

Dimetrodon, genus of extinct primitive predatory reptiles found as fossils in Permian deposits of North America (the Permian Period occurred from 286 to 245 million years ago). *Dimetrodon*, which grew to be more than 3.5 m (11 feet) long, had a large dorsal sail formed by elongated dorsal vertebral spines connected by a membrane containing many blood vessels. The sail probably functioned as a temperature-regulating device. The skull was high and narrow; the region in front of the eyes was long. The many teeth were differentiated into types suited to grasping and holding, to piercing, and to dividing food material into smaller pieces. The body was slim, with a long tail and sprawling limbs not as awkwardly set as in other primitive reptiles; *Dimetrodon* probably could move more effi-

ciently than could its contemporaries, obviously an advantage to a predator. It is probable that the therapsids, the mammallike reptiles that eventually gave rise to the mammals, were descended from *Dimetrodon* or a similar ancestor.

diminished responsibility, legal doctrine that absolves an accused person of part of the liability for his criminal act if he suffers from such abnormality of mind as to substantially impair his responsibility in committing or being a party to an alleged violation. The doctrine of diminished responsibility provides a mitigating defense in cases in which the mental disease or defect is not of such magnitude as to exclude criminal responsibility altogether.

It is most frequently asserted in connection with murder cases requiring proof of a particular mental state on the part of the accused. If a judge or jury concludes that the accused is incapable of premeditation yet has the capacity to appreciate the wrongfulness of his conduct or to conform his behaviour to the requirements of the law, the court can bring a less serious penalty to bear. Generally, the defendant who successfully establishes his abnormal mental condition is found guilty of manslaughter instead of murder.

Few jurisdictions subscribe to the doctrine of diminished responsibility. Although long a part of Scottish homicide law, England and Wales did not adopt the defense until 1957. Most other countries recognize only mental disease or defect of sufficient degree to sustain a defense of insanity. *See also* insanity.

diminishing returns, law of, also called PRINCIPLE OF DIMINISHING MARGINAL PRODUCTIVITY, economic law stating that if one input in the production of a commodity is increased while all other inputs are held fixed, a point will eventually be reached at which additions of the input yield progressively smaller, or diminishing, increases in output.

In the classic example of the law, a farmer who owns a given acreage of land will find that a certain number of labourers will yield the maximum output per worker. If he should hire more workers, the combination of land and labour would be less efficient because the proportional increase in the overall output would be less than the expansion of the labour force. The output per worker would therefore fall. This rule holds in any process of production unless the technique of production also changes.

Early economists, neglecting the possibility of scientific and technical progress that would improve the means of production, used the law of diminishing returns to predict that as population expanded in the world, output per head would fall, to the point where the level of misery would keep the population from increasing further. In stagnant economies, where techniques of production have not changed for long periods, this effect is clearly seen. In progressive economies, on the other hand, technical advances have succeeded in more than offsetting this factor and in raising the standard of living in spite of rising populations.

Dimitrijević, Dragutin, byname APIS ("Holy Bull") (b. Aug. 17, 1876, Belgrade, Serbia [now in Yugoslavia]—d. June 27, 1917, Thessaloniki, Greece), Serbian army officer and conspirator, leader of the terrorist secret society Crna Ruka ("Black Hand").

A young army officer and already a member of the Serbian general staff, Dimitrijević in 1901 initiated an officers' conspiracy to assassinate the unpopular king Alexander Obrenović. The plan was finally carried out in June 1903. Soon thereafter the conspirators succeeded in bringing the army under their control. As a professor of tactics at the military academy, Dimitrijević exerted con-

siderable influence over his students, and he fostered Serbian nationalistic activity abroad. More significantly, he was also a founding member (1911) and inspirational leader of the nationalistic secret society Ujedinjenje ili Smrt ("Union or Death"), better known as the Black Hand, which sought to create a Greater Serbia through the use of violence. Dimitrijević is considered to have played an important role in plotting the assassination of the Austrian archduke Francis Ferdinand at Sarajevo (June 28, 1914), which touched off World War I.

In 1913 Dimitrijević had been appointed chief of general staff intelligence in the Serbian army, and in 1916 he won promotion to colonel. Soon afterward, however, the Black Hand society was marked for elimination by the Serbian premier Nikola Pašić, and in May 1917 Dimitrijević was sentenced to death with six other officers and was executed. He was exonerated of all charges at a staged retrial at Belgrade in 1953.

Dimitrios, also spelled DEMETRIOS, original name DIMITRIOS PAPAPOPOULOS (b. 1914, Constantinople, Ottoman Empire [now Istanbul, Tur.]—d. Oct. 2, 1991, Istanbul), 269th ecumenical patriarch of the Eastern Orthodox church.

After studying at the French *lycée* in the Galata district of Istanbul, Dimitrios Papadopoulos entered the Holy Trinity School of Theology on the island of Heybeli in the Sea of Marmara. He was ordained a priest in 1942, served for a few years as a parish administrator in northern Greece, and was later appointed chaplain to the small Greek community in Tehrān. He was consecrated bishop in 1964 and on Feb. 15, 1972, was appointed metropolitan of Imroz Adasi and Bozca Ada, two Turkish islands in the Aegean Sea that were formerly Greek and that have Greek populations. On July 16, 1972, in Istanbul, the Holy Synod of the Eastern Orthodox church elected Metropolitan Dimitrios patriarch of Constantinople (*i.e.*, ecumenical patriarch), succeeding Athenagoras.

Dimitrov, Georgi Mikhailovich (b. June 18, 1882, Kovachevtsi, Bulg.—d. July 2, 1949, near Moscow, Russia, U.S.S.R.), Bulgarian communist leader who became the post-World War II prime minister of Bulgaria. He also won worldwide fame for his defense against Nazi accusations during the German Reichstag Fire trial of 1933.

A printer and trade union leader, Dimitrov led the Bulgarian socialist parliamentary opposition to the voting of national war credits in 1915, and he played a major role in the formation of the Bulgarian Communist Party in 1919. Briefly imprisoned for sedition in 1918, he later journeyed to the Soviet Union, where he was elected to the executive committee of the Comintern (Communist International) in 1921. In 1923 he led a communist uprising in Bulgaria that provoked ferocious government reprisals. Under sentence of death, he was forced to live abroad, from 1929 in Berlin as head of the central European section of the Comintern. After the Reichstag fire of Feb. 27, 1933, which provided Adolf Hitler, the newly appointed German chancellor, with an excuse for a decree outlawing his communist opponents, Dimitrov was accused with other communist leaders of plotting the fire.

At his trial Dimitrov thoroughly bested the Nazi prosecution and won acquittal. He settled in Moscow and, as secretary-general of the Comintern's executive committee (1935-43), encouraged the formation of popular-front movements against the Nazi menace, except when his patron, Joseph Stalin, and Hitler were cooperating. During 1944 he directed the resistance to Bulgaria's Axis satellite government, and in 1945 he returned to Bulgaria, where he was immediately appointed prime minister of a communist-dominated Fatherland Front

Dimetrodon, restored skeleton

government. Assuming dictatorial control of political affairs, he effected the communist consolidation of power that culminated in the formation of a Bulgarian People's Republic in 1946.

Dimitrovgrad, town, south-central Bulgaria, in the fertile lowlands of the Maritsa River valley; it is a rail junction on the Belgrade-Sofia-Istanbul rail line. The new town, built in 1947 by Bulgarian youth, incorporated three existing villages—Rakovski, Mariino, and Chernokonovo—and is named after the Bulgarian communist leader Georgi Dimitrov. Industries include the manufacture of chemicals, cement, and asbestos; and food canning. The local farms have a high yield of hothouse vegetables. The surrounding lignite-mining area, the Marbas coalfield, supplies the three Maritsa thermal-electric stations. Pop. (2001 est.) 47,100.

Dimitrovgrad, formerly (until 1972) MELEKES, city, Simbirsk *oblast* (province), western Russia at the confluence of the Melekes and Bolshoy (Great) Cheremshan rivers. Founded in 1714, it became a town in 1919 and is an agricultural processing centre, with sawmilling and metalworking industries. It also has an atomic research centre. A teacher-training college is located in the city. Pop. (2000 est.) 124,000.

Dimitrovo (Bulgaria): see Pernik.

Dimitry (personal name): see under Dmitry, or Demetrius.

dimity (from Greek *dimitos*, "of double thread"), lightweight, sheer cotton fabric with two or more warp threads thrown into relief, forming fine cords. Originally dimity was made of silk or wool, but since the 18th century it has been woven almost exclusively of cotton.

The name was applied to two types of corded cottons: a heavy material used for bedcovers, drapery, and the like, and a lightweight, almost sheer fabric either corded or made in check effects. Dimity now refers primarily to the latter.

Dimona, town of the Negev, southern Israel, on the main highway from Beersheba (Be'er Sheva') to Sedom (Sodom). It is named for the biblical city of Dimonah, mentioned (Joshua 15:21–22) as "belonging to . . . Judah in the extreme South."

Modern Dimona was established in 1955 as a residential centre for the workers of the Dead Sea Works at Sedom, 29 miles (47 km) east by road. The site was picked largely because of its elevation (about 1,968 feet [600 m] above sea level and almost 3,281 feet above the Dead Sea) and consequent cool nights. By the 1970s the population of Dimona had greatly exceeded the planned figure of about 5,000. In addition to the employees of the Dead Sea Works, many of whom later moved to 'Arad, several miles closer to Sedom, it houses the workers of the phosphate mines at Oron, 14 miles (23 km) south. Dimona has textile mills, and porcelain articles are also manufactured. Nearby is the Negev Nuclear Research Center, with a 26-megawatt reactor. Dimona is connected to the national railway grid by a line from Beersheba. Inc. 1969. Pop. (1997 est.) 32,828.

Dimorphodon, genus of extinct flying reptiles found as fossils in European deposits from the Early Jurassic Period (occurring 208 to 187 million years ago). *Dimorphodon*, among the most primitive of the known pterosaurs (flying reptiles), was about 1 m (3 feet) long. The head was very large and deep, and the skull had several large openings. Two types of teeth are found in the jaws: several large pointed ones in the front and many smaller teeth in the back. The limbs were well developed; it is unclear whether the animal habitually walked

on two legs. The wings consisted of thin membranes of skin that stretched from the enormously elongated fourth finger of each hand to the hind limbs. On the ground, the animal probably folded its wings, much as do modern bats. The three remaining fingers of each forelimb were well developed and probably able to support the animal on the ground; these fingers also were used for grasping and were clawed. The eyes were large.

Dimorphodon certainly was not as efficient a flier as the modern birds; it lacked the large keel to which the powerful flight muscles of birds are attached; gliding rather than wing beating was probably the normal mode of flight for the animal.

Dimyat (Egypt): see Damietta.

Din-i Ilāhī (Persian: "Divine Faith"), an elite eclectic religious movement, which never numbered more than 19 adherents, formulated by the Mughal emperor Akbar in the late 16th century AD.

The Din-i Ilāhī was essentially an ethical system, prohibiting such sins as lust, sensuality, slander, and pride and enjoining the virtues of piety, prudence, abstinence, and kindness. The soul was encouraged to purify itself through yearning for God (a tenet of Sūfism, Islāmic mysticism), celibacy was condoned (as in Catholicism), and the slaughter of animals was forbidden (as in Jainism). There were no sacred scriptures or a priestly hierarchy in the Din-i Ilāhī. In its ritual, it borrowed heavily from Zoroastrianism, making light (Sun and fire) an object of divine worship and reciting, as in Hinduism, the 1,000 Sanskrit names of the Sun.

In practice, however, the Din-i Ilāhī functioned as a personality cult contrived by Akbar around his own person. Members of the religion were handpicked by Akbar according to their devotion to him. Because the emperor styled himself a reformer of Islām, arriving on Earth almost 1,000 years after the Prophet Muḥammad, there was some suggestion that he wished to be acknowledged as a prophet also. The ambiguous use of formula prayers (common among the Sūfis) such as *Allāhu akbar*, "God is most great," or perhaps "God is Akbar," hinted at a divine association as well.

Akbar is recorded by various conflicting sources as having affirmed allegiance to Islām and as having broken with Islām. His religion was generally regarded by his contemporaries as a Muslim innovation or a heretical doctrine; only two sources from his own time—both hostile—accuse him of trying to found a new religion. The influence and appeal of the Din-i Ilāhī were limited and did not survive Akbar, but they did trigger a strong orthodox reaction in Indian Islām.

Dinah, also spelled DINA, in the Old Testament (Genesis 30:21; 34; 46:15), daughter of Jacob by Leah; Dinah was abducted and raped near the city of Shechem, by Shechem, son of Hamor the Hivite (the Hivites were a Canaanitish people). Because Shechem then wished to marry Dinah, Hamor suggested to Jacob that their two peoples initiate a policy of commercial and social intercourse. Dinah's brothers Simeon and Levi pretended to agree to the marriage and the covenant if Shechem and all the other males of the city of Shechem were circumcised. After the operations, while the men were still weakened, Simeon and Levi attacked the city, killed all the males, including Shechem and Hamor, and freed Dinah. They then joined in plundering the city. Jacob rebuked Simeon and Levi for arousing the enmity of neighbouring tribes and, on his deathbed, gave his blessing to their younger brother Judah, reproving Simeon and Levi for their cruelty.

Dinājpur, town, northwestern Bangladesh, just east of the Punarbhāba River. The old

city and the former residence of the maharaja of Dinājpur are located in the northeastern quarter of the town. Dinājpur contains jute and rice mills, jute-seed farms, and a thermal power station. It houses several government colleges affiliated with the University of Rājshāhi.

The area in which Dinājpur is located is a flat alluvial plain intersected by rivers and broken by the slightly elevated Bāring tract. It is an important rice, wheat, jute, and sugarcane growing area. Pāla remains (9th century AD) are scattered throughout the area. Pop. (1991) city, 138,000.

Dinan, town, northwestern France, in Côtes-d'Armor *département*, Bretagne *région*, dominating the upper Rance Estuary. It stands on a height above the left bank of the river 14 miles (22 km) south of the coast at Dinard. It has preserved many medieval timbered houses, as

Section of the old walls of Dinan, Fr., with one of the 15 towers
J Allan Cash Ltd

well as its fine 18th-century granite buildings, its Gothic bridge, and its 15th-century belfry, the Tour de l'Horloge. The walls of the town, dating from the 11th century, survived two 14th-century attacks by the English. An imposing granite castle, known as the Château de la Duchesse Anne, was built by the dukes of Brittany in the 14th and 15th centuries. Dinan is a market town and a tourist centre; textiles are also manufactured. Pop. (1999) 10,967.

Dinan, SAINT: see Ninian, Saint.

dinanderie, type of late medieval brass ware made in and around Dinant, Belg.

Brass does not appear to have been used extensively in Europe until the 11th or 12th century, when a considerable industry was established in the Low Countries in the district near the Meuse (Maas) River. By the 15th century its centre, Dinant, had become a prosperous town the name of which was synonymous with excellent brass ware. Included in the production were such domestic articles as ewers, fire irons, candlesticks, dishes, and basins and such ecclesiastical objects as censers, aquamaniles, fonts, and lecterns.

When the town was sacked in 1466 by Charles the Bold, son of Philippe III le Bon,

duke of Burgundy, the craftsmen dispersed, and the industry spread to other towns along the Meuse and to Brussels, Bruges, and Tournai, eventually establishing a new production centre in Aachen. Some of the fleeing "brass-

Dinanderie plate, brass, from Dinant or Malines, Belg., c. 1480; in the Irwin Untermyer Collection
By courtesy of Irwin Untermyer

beaters" may have gone as far as Nürnberg, which was already becoming famous for its metalworking and was soon to achieve the prominence of the old centres. In the late 15th and 16th centuries the "basin-beaters" of Nürnberg produced numerous embossed dishes and basins of a characteristic type, which were exported to most parts of Europe. These objects have also come to be known as dinanderie.

The earliest type of dinanderie, Gothic in feeling and outline, is generally small and deep and made of a golden-coloured brass. Pieces from the 16th century and later are flatter, larger, and of a darker colour. The embossed decoration, executed with large stamps, falls into two major categories: religious and allegorical subjects and stylized decorative patterns. Additional ornament was provided by punched bands of simple motifs repeated around the rim and encircling the main subject in the centre of the bowl. Many have a raised central boss in the form of an open rose with radiating petals, and some bear inscriptions in Gothic lettering or pseudo-Gothic-Islamic script. They are quite often found in churches, where they have been used as alms dishes.

Dinant, municipality, Namur province, southern Belgium, on the Meuse River below steep limestone cliffs, south of Namur. Inhabited in Roman times, Dinant's name probably derives from Diana, Roman goddess of the hunt. A fortified burgh in Merovingian and Carolingian times, it was a dependency of the

Dinant, Belg., on the Meuse River, showing the citadel atop the cliff and the Church of Notre Dame (right)

Thomas Friedmann—Photo Researchers

bishop of Tongres in the 7th century and a fief of the bishops of Liège from 1070 to the French Revolution. It was famous for artistic metalwork (dinanderie) from the 13th century until it was sacked by Charles the Bold (1466). Dinant was occupied by the French for nearly 30 years after 1675 and again during the Napoleonic Wars. It was nearly destroyed by the Germans in 1914 and was damaged again during World War II.

A rail junction and tourist centre, it manufactures wool and textiles in addition to the traditional copper and brass ware and *couques de Dinant* (decorated biscuits). Landmarks include the 11th-century citadel 300 ft (90 m) above the river on top of a cliff; the Montfort Tower and the Church of Notre Dame (with its bulbous clock tower), both 13th century; and Rocher Bayard, the sentinel rock, 130 ft high. Prehistoric caverns and stalactite grottoes along the river and many ruined castles and châteaux attract tourists.

Near Dinant, at Hastière, is an 11th-century church in the Roman style with a Gothic choir. Also nearby is Fierfooz National Park containing Roman baths, reconstructed on original foundations, and other archaeological remains. Pop. (1990 est.) mun., 12,208.

Dinarchus, also spelled **DEINARCHUS** (b. c. 360 BC—d. after 292), professional speech writer at Athens whose work is generally thought to reflect the incipient decline of Attic oratory.

Dinarchus came to prominence in the scandal that followed the flight to Athens in 324 BC of Alexander the Great's treasurer, Harpalus, who brought with him considerable wealth derived from the spoils of Alexander's conquest of Asia. Dinarchus wrote the prosecution speeches against Demosthenes and other well-known politicians accused of misappropriating some of this money, and the three extant works generally ascribed to him are all concerned with these trials. The works are "Against Demosthenes," "Against Aristogiton," and "Against Philocles." Dionysius of Halicarnassus records the titles of 87 speeches ascribed to Dinarchus, 60 of which he considered genuine. Dionysius' low opinion of the orator is supported, in the extant speeches, by the lack of creative skill, use of violent abuse in place of reasoned judgment, and plagiarism from other orators.

Dinaric Alps, Serbo-Croatian **DINARSKO GORJE**, or **DINARA PLANINA**, southeastern division of the Eastern Alps, running parallel to the Dalmatian (Adriatic) coast from Trieste and Slovenia south to Albania. Bounded by the Soča (Italian Isonzo) and Sava rivers (north), the Drina River (south), the Kolubara, Ibar, and Sitnica rivers (east), and the Adriatic Sea (west), the Alps rise to 8,274 ft (2,522 m) in Bobotov Kuk of Durmitor. The coast is indented with numerous natural harbours, but the limestone ranges prohibit any natural access to the agricultural hinterland. Interior basins of the range, though isolated, have both fertile soils and dense population.

Dinawarī, ad-, in full **ABŪ ḤANĪFAH AḤMAD IBN DĀ'ŪD AL-DĪNAWARĪ** (b. c. 815—d. c. 895/902), Persian astronomer, botanist, and historian, whose interest in Hellenism and the Arabic humanities has been compared with that of the Iraqi scholar al-Jāhiz.

Ad-Dinawarī studied philology in the Iraqi cities of Basra and Kūfah. The systematic approach to learning that he acquired there is reflected in the preserved fragments of his *Kitāb an-nabāt* ("Book of Plants"), one of the most famous early Muslim works on botany. Of lexicographical character, it includes oral and written Arabic botanical traditions as well as much Persian material. Written in beautiful prose, it was the standard work in the field for generations. None of ad-Dinawarī's

works on mathematics or the Qur'ān have been preserved. There are, however, fragments of his observations on astronomy, *Kitāb al-anwā'*. The only work that has survived in full is *al-akhbār at-tiwāl* ("The Long Narratives"), a history of Persia written from the Persian, rather than the Arabic, viewpoint.

Dinbych (Wales): see Denbigh.

Dinder National Park, park, eastern Sudan. The park lies in the clayish flood plain of the Nahr (river) ad-Dindar and Nahr ar-Rahad, at an elevation of 2,300 to 2,600 ft (700 to 800 m). Established in 1935, it covers an area of 2,750 sq mi (7,123 sq km). Vegetation in the park consists of thornbush savannah in the north and woodland in the south; along the riverbanks there are palm or gallery forests and swampy areas. Wildlife includes giraffe, hartebeest, reedbuck, roan antelope, bushbuck, oribi, waterbuck, greater kudu, gazelle, dik-dik, buffalo, lion, and ostrich. Black rhinoceros, leopard, cheetah, elephant, hyena, and jackal are also occasionally found. The park can be reached by road from Khartoum, a distance of 290 mi (470 km). Its headquarters are at Khartoum.

Dinder River, ARABIC NAHR AD-DINDAR, tributary of the Blue Nile, rising in the Ethiopian highlands west of Lake Tana. It flows northwest past Dongur, descends into the Sudanese plain, and runs in numerous meanders to join the Blue Nile below Sannār, The Sudan. The river, 300 mi (480 km) long, is navigable for the lower one-third of its course during the flood season (June–September). Its middle course in The Sudan flows through Dinder National Park.

Dindigul, city, Tamil Nādu state, southeastern India. Situated between the Palni and Sirumalai hills, it is a road transport hub. Its name, derived from the words *tinṭu kal* ("pillow rock"), refers to the bare hill dominating the city. The fortress, built on the hill during the Vijayanagar era (1336–1565), was used in Hindu, Muslim, and British wars from the 17th to the 19th centuries. The contemporary city contains large-scale cotton spinning and weaving mills, as well as such handicraft industries as silk weaving and the manufacture of jewelry and cigars. Dindigul houses two liberal arts colleges, affiliated to Madurai-Kamaraaj University. Pop. (1991 prelim.) 182,293.

d'Indy, (Paul-Marie-Théodore-)Vincent: see Indy, (Paul-Marie-Théodore-)Vincent d'.

Dine, Jim, byname of **JAMES DINE** (b. June 16, 1935, Cincinnati, Ohio, U.S.), American painter, graphic artist, sculptor, and poet who

Dine, photograph by Hans Namuth, 1964
Hans Namuth

emerged during the Pop Art period as an innovative creator of works that combine the painted canvas with ordinary objects of daily life.

Dine studied at the Boston Museum of Fine Arts School and at Ohio University. His early work consists primarily of images on canvas.

to which three-dimensional objects (e.g., articles of clothing, garden tools) are attached. His "Shoes Walking on My Brain" (1960), for example, is a childlike painting of a face with a pair of leather shoes fixed to the forehead. His reputation was secured during the 1960s by his wittily incongruous painted images of tools, clothes, and other utilitarian and household objects. Dine's work of the 1970s pursued the same subject matter but showed a growing preoccupation with graphic media. His exploitation of nuances of line and texture is especially evident in his images of flowers and portraits of his wife done in the late 1970s. Dine also illustrated or coauthored several books.

Isak Dinesen, 1959
AP/Wide World

Dinefwr, district, Dyfed county, southern Wales. Created in the administrative reorganization of 1974, it covers an area of 375 square miles (971 square km) and rises from an elevation of just over 100 feet (30 m) in the Tywi valley in central Dinefwr to heights of more than 2,000 feet (600 m) in the Black Mountains to the south. Dinefwr district is bordered by the districts of Ceredigion to the north, Brecknock to the east, Lliw Valley and Llanelli to the south, and Carmarthen to the west. The district's town of Llandovery was of strategic importance in Roman times, and the Church of Llanfair (restored 1915) nearby was built within the ramparts of a Roman fort. The ruins of the 13th-century Dynevor Castle are located just west of Llandeilo. Originally built in AD 876 by the Welsh nobleman Rhodri Mawr, the castle was taken by the English in the 13th century and rebuilt; the Welsh leader Owen Glendower tried to retake it in 1408 but failed.

Dinefwr is a rural district in which dairy farming is the main agricultural activity. Both Llandovery and Llandeilo are agricultural market towns, and Llandeilo is also the administrative seat for the district. Dinefwr's limited industry is located in Ammanford, a mining centre situated on an anthracite coalfield surrounded by scenic countryside. Many tourists visit the district as most of its eastern half lies within Brecon Beacons National Park. The County Agricultural College is in Llandeilo. A highway and a railway extend south from Llandovery through Llandeilo and Ammansford. Pop. (1986 est.) 37,200.

Dines, William Henry (b. Aug. 5, 1855, London, Eng.—d. Dec. 24, 1927, Benson, Oxfordshire), British meteorologist who invented instruments to measure atmospheric properties.

The son of a meteorologist, Dines was graduated from Corpus Christi College, Cambridge, with honours. He became interested in wind speed and invented a pressure-tube anemometer, the first device to measure both the velocity and direction of wind. Dines pioneered in the use of kites and balloons for upper-air measurement and designed a remarkable meteorograph for upper-air soundings weighing only about 2 ounces (60 g). This became for years the standard British instrument for upper-atmosphere soundings and provided many data on pressure, temperature, and humidity in heights well into the stratosphere. His analysis of these data revealed striking correlations between properties of the upper air and yielded valuable insights into the dynamics of cyclones and anticyclones. He also added to knowledge of terrestrial and solar radiation. Dines's collected scientific papers with a full bibliography were published in 1931 by the Royal Meteorological Society, of which he was president in 1901–02. In 1905 he was elected a fellow of the Royal Society.

Dinesen, Isak, pseudonym of KAREN CHRISTENSE DINESEN, BARONESS BLIXEN-FINECKE (b. April 17, 1885, Rungsted, Den.—d. Sept. 7, 1962, Rungsted), Danish writer whose finely crafted stories, set in the past and pervaded

with an aura of supernaturalism, incorporate the themes of eros and dreams.

Educated privately and at the Academy of Fine Arts, Copenhagen, Dinesen married her cousin, Baron Bror Blixen-Finecke, in 1914, and went with him to Africa. There they owned and directed a coffee plantation in Kenya and became big-game hunters. After her divorce in 1921 she continued to operate the plantation for 10 years until mismanagement, drought, and the falling price of coffee forced her return to Denmark.

Her years in Kenya are recorded in a nonfiction book, *Out of Africa* (1937; *Den afrikanske farm*). These highly regarded memoirs of her years in Kenya reveal an almost mystical love of Africa and its people. The book is a poetic reminiscence of her triumphs and her sorrows on the loss of her farm, the death of her companion, the English hunter Denys Finch Hatton, and the disappearance of the simple African way of life she admired. In 1944 she produced her only novel *Gengældelsens veje* (*The Angelic Avengers*) under the pseudonym Pierre Andrézel. It is a melodramatic tale of innocents who defeat their apparently benevolent but actually evil captor, but Danish readers saw in it a clever satire of Nazi-occupied Denmark.

She initially wrote first in English and then rewrote her books in Danish, but her later books usually appeared simultaneously in both languages. Dinesen's characteristic writings were in the form of tales—highly polished narratives in the Romantic tradition. Collections include *Seven Gothic Tales* (1934; *Syv fantastiske fortællinger*), *Winter's Tales* (1942; *Vinter-eventyr*), and *Last Tales* (1957; *Sidste fortællinger*). *Carnival: Entertainments and Posthumous Tales* (1977) includes uncollected or hitherto unpublished stories. Her other posthumously published works include *Daguerreotypes, and Other Essays* (1979) and *Letters from Africa, 1914–31* (1981).

BIBLIOGRAPHY. Judith Thurman, *Isak Dinesen* (1982), is a fine biography utilizing Dinesen's private papers and letters.

ding (Chinese vessel): see ting.

Ding Ling, Wade-Giles romanization TING LING, pseudonym of CHIANG WEI-CHIH (b. 1904, Changde, Hunan province, China—d. March 4, 1986, Peking), one of China's most popular 20th-century authors. In her early career Ding Ling initially wrote highly successful short stories centring on young, unconventional Chinese women, and she began writing proletarian works in 1931.

Born into a declining gentry family, Ding Ling was supported by her mother after her father's death in 1911. After formal education in Hunan provincial schools, she journeyed in 1921 to Shanghai and then to Nanking, more to observe the intellectual life there than to study. In that period she developed an interest in anarchism. After a stint at Shanghai University, she went to Peking, where she met and fell in love with the leftist would-be poet Hu Yeh-p'in (1925). With him she moved to the Western Hills outside Peking.

Influenced by Flaubert's *Madame Bovary* and other European novels, Ding Ling began writing, partly autobiographic short stories in which she developed a new kind of Chinese heroine—daring, independent, and passionate, yet perplexed and emotionally unfulfilled in her search for the meaning of life. Ding Ling's chronicles of the aspirations and disappointments of modern Chinese women were an immediate success, but because Hu Yeh-p'in was making little progress in his literary career, the couple moved to Shanghai in 1928 to start a literary magazine as a vehicle to publish his work. The venture failed, and Hu Yeh-p'in turned his attention to politics, joining the League of Left-wing Writers. Ding Ling, however, devoted herself to writing, and by 1930 she had completed three collections of short stories and a novelette. Later that year she gave birth to a son. Hu Yeh-p'in joined the Chinese Communist Party and became even more involved in politics, only to be arrested by Nationalist authorities and executed in 1931. Ding Ling joined the Communist Party that same year and edited journals of the League of Left-wing Writers.

Ding Ling's conversion to Marxism channelled her writing into a new and initially fruitful direction. Her proletarian-oriented *Shui* (1931; "Flood") was acclaimed as a model of Socialist Realist fiction in China. She was abducted by agents of the Nationalist Party in 1933 and imprisoned until 1936, when, disguised as a soldier, she escaped and joined the Communists at Yanan. There she became friendly with Mao Zedong and was linked romantically with the general Peng Dehuai. She was not completely uncritical of the Communist movement, expressing her dissatisfactions openly through her stories and in journal articles, for which she was censured by Mao.

Ding Ling's officially successful proletarian novel *T'ai-yang chao tsai Sang-kan-ho shang* (1948; "The Sun Shines over the Sang-kan River") was the first Chinese novel to win the Soviet Union's Stalin Prize (1951). Yet despite her triumphs, she remained in political trouble for her open criticisms of the party, especially in regard to women's rights. She was officially censured and expelled from the party as a rightist in 1957 and was imprisoned for five years during the Cultural Revolution. In 1975 she was freed, and her membership in the Communist Party was restored in 1979. Her later publications include several critical essays, short stories, and longer fictional prose.

Dingane, also spelled DINGAAN (d. 1843), Zulu king of Natal (1828–40) who assumed power after taking part in the murder of his half brother Shaka in 1828. In November 1837 Dingane promised the Boer leader Piet Retief almost all of Natal in return for the recovery of a stolen herd of cattle. Despite their success, Retief and about 600 Boer immigrants were massacred by the Zulu in February 1838. These deaths were avenged by Andries Pretorius on Dec. 16, 1838 (Battle of Blood River), when 3,000 Zulu warriors were killed in battle. Dingane was finally overthrown by his brother Mpande in January 1840 and fled to Swaziland, where he was murdered in 1843.

Dingelstedt, Franz Ferdinand, Freiherr von (count of) (b. June 30, 1814, Halsdorf, Hesse-Kassel [Germany]—d. May 15, 1881, Vienna, Austria), German poet, playwright, and theatrical producer known for his biting political satires.

A member of the liberal Young Germany movement, Dingelstedt became a teacher. He also wrote political satires against the German princes, *Lieder eines Kosmopolitischen Nachtwächters* (1841; "Songs of a Cosmopolitan Nightwatchman"), one of which, *Die Neuen Argonauten* ("The New Argonauts"),

led to his dismissal. Between 1841 and 1843 he was a correspondent in Paris and London and underwent a political conversion that marked the beginning of his career as a state official. He was appointed manager of the court theatres at Munich and Weimar and, later, director of the opera and Hofburgtheater at Vienna, and he was ennobled by the king of Bavaria. He was responsible for splendid new productions of the German classics and of plays by William Shakespeare. He was also

Dingelstedt, engraving by A. Weger after a photograph
Bavaria-Verlag

the founder of the German Shakespeare Society, and he translated many of Shakespeare's plays. Dingelstedt also wrote novels and an autobiographical sketch, *Münchener Bilderbogen* (1879; "Picture Sheet of Munich").

Dingiswayo (d. 1817), chieftain, from 1807, of the Mtetwa clan of the North (Natal) Nguni division of the Bantu people.

Dingiswayo became the paramount chief of about 30 peoples in Zululand (now northeastern Natal province, Republic of South Africa). His policy of conquering nearby Nguni peoples and absorbing them into a rudimentary centralized state was carried on by Shaka, the Zulu whom he chose as his successor. Dingiswayo initiated trade with the Portuguese in Mozambique. He was assassinated by Zwide, chief of the Ndwandwe clan, who rebelled against Dingiswayo's rule in Zululand.

Dingle, peninsula and bay in County Kerry, on the southwestern coast of Ireland. The peninsula begins south of Tralee as the Slieve Mish range, with elevations of more than 2,000 feet (600 m); but in the west it becomes a mixture of hills and lowlands, with a north-trending line of hills near the town of Dingle. This ridge includes Brandon Mountain (3,127 feet [953 m]) and ends in some spectacular cliffs. The mountains are penetrated by heavily glaciated valleys. The extreme west of the peninsula comprises mainly lowlands, particularly around the harbours at Dingle, Ventry, and Smerwick. The peninsula terminates in the Blasket Islands. Dingle Bay separates the Dingle peninsula from the Iveragh peninsula to the south.

dingo (species *Canis dingo*), also called **WAR-RIGAL**, Australian wild dog (family Canidae), one of the few nonmarsupial mammals in Australia. Some authorities regard the dingo as a subspecies of the domestic dog, hence *C. familiaris dingo*. The dingo was apparently introduced from Asia during the later immigrations of Aborigines in post-Pleistocene times (perhaps 5,000 to 8,000 years ago). Similar to the domestic dog in structure and habits, the dingo is stout with short, soft fur, a bushy tail, and erect, pointed ears. It is about 1.2 m (4 feet) long, including the 30-centimetre (12-inch) tail, and stands about 60 cm at the shoulder. Its colour varies between yellowish and reddish brown, often with white underparts, feet, and tail tip.

Dingo (*Canis dingo*)
G.R. Roberts

Dingos hunt alone or in small groups; they formerly preyed on kangaroos but now feed principally on rabbits and sometimes on livestock. Through competition they contributed to the extermination of the native Tasmanian wolf and Tasmanian devil (both marsupials) on the Australian mainland. With the European settlement of Australia, they preyed on sheep and poultry and were consequently eliminated in most areas. Wild dingoes, although bold and suspicious, can be tamed, and those raised from puppies may become affectionate pets. The Aborigines sometimes capture and tame them. Dingoes normally only yelp and howl, but when domesticated they can also imitate the bark of dogs. They usually bear litters of four to five pups; the gestation period is about 63 days.

Dinguiraye, town, north-central Guinea. It lies at the eastern edge of the Fouta Djallon plateau. The town was once the seat of the imamate (region ruled by a Muslim religious leader) of Umar Tal, whose jihad (holy war) led to the creation of the Tukolor empire (1850–93) in the Niger River valley. Dinguiraye is now connected by road with the towns of Sigui and Dabola. It is the chief trading centre for rice, millet, peanuts (groundnuts), and cattle produced in the surrounding area by the Tukolor, Fulani, and Dialonke (Djallonke) peoples. Alluvial gold is extracted from the upper reaches of the Tinkisso River (a tributary of the Niger) east of the town. Pop. (1983 prelim.) 32,065.

Dinh Bo Linh, reign title **DINH TIEN HOANG** (b. Hoa Lu, northern Vietnam—d. 979, northern Vietnam), emperor and founder of the second Vietnamese dynasty, who, after a decade of anarchy, reunified his country, winning official recognition of Vietnam as a state independent from China.

According to Vietnamese annals, Dinh Bo Linh, of peasant ancestry, was the adopted son of a feudal lord, the prefect of Hoa Lu. He was one of 12 chieftains among whom was divided Nam Viet, which consisted of northern Vietnam and three central Vietnamese provinces. Dinh Bo Linh defeated each of the other 11 lords and by 968 had gained control of all Nam Viet. Proclaiming himself emperor, he called the reunited country Dai Co Viet.

Dinh Tien Hoang eliminated the social and political anarchy that had characterized the divided kingdom. He filled administrative positions with Buddhist and Taoist monks, who were subordinate to government and imperial control, and he organized his state in a form adapted from the Chinese model that was familiar to the Viets, which stressed loyalty and individual performance of duties.

Dinh Tien Hoang sought peaceful relations with China. Exploiting the weakness of the newly installed Sung dynasty, he affirmed the subordinate status of his kingdom and agreed to pay tribute to the Chinese emperor in return for recognition of the sovereignty of

Dai Co Viet and its ruler. He thus achieved permanent independence from China for the Vietnamese kingdom, although China sought unsuccessfully to reclaim the territory in centuries to come.

Dinh Tien Hoang was known as a courageous warrior and an able administrator and diplomat, but his authoritarian regime and his fondness for courtly pleasures made him many enemies, even within his family and his court. He and the crown prince were assassinated in 979 by a mystic seer who envisioned himself as the true emperor of Dai Co Viet. Because the emperor's heirs were too young to assert their position, the Dinh dynasty fell within a year of his death.

Dinichthys, also called **DUNKLEOSTEUS**, extinct genus of arthrodires, *i.e.*, primitive, armoured, fishlike animals that dominated ancient seas. *Dinichthys* lived during the Late Devonian Period (374 to 360 million years ago) and is found fossilized in rocks of that age in Europe, northern Asia, and North America. *Dinichthys* grew to a length of about 9 m (30

Dinichthys terrelli, reconstructed head
By courtesy of the Cleveland Museum of Natural History

feet), more than 3 m of which consisted of an armoured head shield that was hinged in the neck region, permitting the upper jaw to be raised in relation to the lower. *Dinichthys* was clearly the dominant marine predator of its time.

Dinis, also spelled **DINIZ**, English **DENIS** (b. Oct. 9, 1261—d. Jan. 7, 1325), sixth king of Portugal (1279–1325), who strengthened the kingdom by improving the economy and reducing the power of the nobility and the church.

The son of Afonso III, Dinis was educated at a court subject to both French and Castilian cultural influences and became a competent poet. He founded the first university in Portugal—in Lisbon—in 1290. A skilled negotiator, Dinis was able to establish with Castile a definitive frontier for Portugal. At home, he made the authority of the crown supreme, intervening in local government, reducing the power of the nobility, and combating the supremacy of the clergy, particularly in regard to their territorial wealth (laws of disinheritance in 1286, 1291, and 1309). Concordats with the papacy (1289 and 1290) ended the struggle with the church.

Dinis took a special interest in the land, encouraging forestry plantation and the fuller development of the country's agricultural resources. He also showed great concern for shipbuilding and for the extension and protection of commerce. The last years of the reign were disturbed by a rebellion of his son, the future Afonso IV, who succeeded to the throne on his father's death. Dinis' wife would become Saint Elizabeth (Isabel) of Portugal.

Dinis, Júlio, pseudonym of **JOAQUIM GUILHERME GOMES COELHO** (b. Nov. 14, 1839, Porto, Port.—d. Sept. 12, 1871, Porto), poet, playwright, and novelist, the first great novelist of modern Portuguese middle-class society. His novels, extremely popular in his lifetime and still widely read in Portugal today, are

Dinis, detail of a watercolour by Alfredo Roque Gameiro, 19th century

By courtesy of the Secretana de Estado da Informaçao e Turismo, Lisbon

written in a simple and direct style accessible to a large public.

His first attacks of tuberculosis forced him to resign as deputy professor at the medical school of Porto. He had already published several tales of country life in the *Jornal do Porto*. Retiring to the coastal town of Ovar for his health, he wrote the novel for which he is best-known, *As Pupilas do Senhor Reitor* (1867; "The Pupils of the Dean"), depicting country life and scenery in a simple and appealing style. It was based on his own family situation and described the influence of the English on Portuguese culture. (His mother was English.) Encouraged by its immediate success, he published *Uma Família Inglesa* (1868; "An English Family"), a novel describing English society in Porto.

Dinis' poems and plays were published posthumously, but he is best-remembered for his novels. *As Pupilas do Senhor Reitor* had gone through 14 editions by 1900.

Dinka, also called **JIENG**, people who live in the savanna country surrounding the central swamps of the Nile basin in the south of The Sudan. Numbering about 2,960,000 in the late 20th century, the Dinka speak an Eastern Sudanic language of the Chari-Nile branch of the Nilo-Saharan family and are closely related to the Nuer. They form many independent

Dinka village on the Nile River in the southern Sudan
Henriette Grindat

groups of between 1,000 and 30,000 persons. These are grouped on a regional, linguistic, and cultural basis into clusters, of which the best-known are the Agar, Aliab, Bor, Rek, and Malual. The Dinka are primarily transhumant pastoralists, moving their herds of cattle to riverine pastures during the dry season (December to April) and back to permanent settlements in savanna forest during the rains, when their food crops, principally millet, are grown. Each group is internally segmented into smaller political units with a high degree of autonomy. Because of the vast geographical area they occupy, the Dinka exhibit great diversity of dialect, although they value intra-group unity in the face of enemies.

By tradition certain of their patrilineal clans

provide priest-chiefs ("masters of the fishing spear"), whose position is validated by elaborate myths. Spiritual leadership and intervention are important to the Dinka, who are intensely religious and for whom God (Nhial) and many ancestral spirits play a central and intimate part in everyday life. Anything from a lie to a murder may be an occasion for sacrificial propitiation of the divine.

Proud, independent, and warlike, the Dinka ritualize the passage from boyhood to manhood through age-old ceremonies during which a number of boys of similar age undergo hardship together before abandoning forever the activity of milking cows, which had marked their status as children and servers of men.

Dinkelsbühl, city, Bavaria *Land* (state), southern Germany. It lies along the Wörnitz River, about 20 miles (32 km) southwest of Ansbach. Mentioned in 928, it was fortified in the 10th century and became a free imperial city in 1273. It flourished in the 14th and 15th centuries and successfully withstood eight sieges in the Thirty Years' War (events commemorated annually in a July festival) before it fell to Gustavus Adolphus of Sweden in 1632. The 10th-century walls, with a moat and 12th-century towers, still surround the city, thus preserving its medieval character. Notable landmarks include the late Gothic Church of St. George (1448–99; one of Germany's finest single-naved churches, with a Romanesque tower), the old castle of the Teutonic Order (rebuilt 1761–64), the fortified town mill (c. 1390), and the Deutsche Haus (a 14th–15th-century mansion, with a Renaissance facade). Gingerbread, furniture, textiles, clothing and leather, and beer are produced in the city. Pop. (1989 est.) 10,668.

Dinnsheanchas (Gaelic: "Histories of Places"), studies in prose and verse of the etymology and history of place-names in Ireland—e.g., of streams, raths (strongholds of ancient Irish chiefs), mounds, and rocks. These studies were preserved in variant forms in monastic manuscripts dating from as early as the 12th century. The *Dinnsheanchas* contain much pre-Christian mythology, especially stories of gods and fairies. The most famous study is the *Dinnsheanchas*; it describes more than 200 locations and is ascribed to Amergin mac Amhalgaidh, a poet to King Diarmaid in the 6th century. It was an important source for Irish poets, who were expected to be familiar with the lore of each area.

Dinocrates, also spelled **DEINOCRATES** (fl. 4th century BC), Greek architect who prospered under Alexander the Great. He tried to captivate the ambitious fancy of that king with a design for carving Mount Athos into a gigantic seated statue. The plan was not carried out, but Dinocrates designed for Alexander the plan of the new city of Alexandria (c. 330 BC) and constructed the vast funeral pyre of Hephaestion. Alexandria was, like Piraeus and

Rhodes, built on a regular plan in contrast to the narrow and irregular streets of most earlier towns.

dinoflagellate, any of numerous one-celled, aquatic organisms bearing two dissimilar flagellae and having characteristics of both plants and animals. Most are microscopic and marine. Botanists place them in the algal class Dinophyceae of the division Pyrrophyta, and zoologists claim them as members of the protozoan order Dinoflagellida. Dinoflagellates range in size from about 5 to 2,000 micrometres (0.0002 to 0.08 inch). Nutrition among dinoflagellates is plantlike, animal-like, or mixed; many species are parasitic or commensal. The group is an important component of phytoplankton in all but the colder seas and is

Dinoflagellate *Noctiluca scintillans* (magnified)

Douglas P. Wilson

an important link in the food chain. Dinoflagellates also produce part of the luminescence sometimes seen in the sea.

The dinoflagellate cell is banded by a median or coiled groove, the annulus, which contains a flagellum. A longitudinal groove, the sulcus, extends from the annulus posteriorly to the point at which a second flagellum is attached. Armoured dinoflagellates are covered with heavy, cellulose plates, which may have long, spiny extensions; some species lacking armour have a thin pellicle (protective layer). Dinoflagellates have yellowish or brownish plastids (pigment-containing bodies) and may store food in the form of starches, starchlike compounds, or oils.

Although sexual processes have been demonstrated in one genus, reproduction is largely by binary or multiple fission. Under favourable conditions dinoflagellate populations may reach 60,000,000 organisms per litre of water. Such rapid growths, called blooms, result in the red tides that discolour the sea and poison fish and other marine animals.

For additional information on specific dinoflagellate genera, see *Ceratium*; *Gymnodinium*. See also red tide.

Dinohyus, extinct genus of giant piglike mammals found as fossils in deposits of early

Miocene age in North America (the Miocene Epoch occurred 23.7 to 5.3 million years ago). *Dinohyus* is the last and largest of a group of mammals called entelodonts, an early offshoot of the primitive swine stock. As large as a bison, it stood at least 2 m (6 feet) tall at the shoulder; the skull alone was about 1 m (more than 3 feet) long and had many bony flanges and protuberances. The braincase was extremely small. The teeth were very distinctive: the incisors were blunt, while the canines were stout and must have been effective weapons. The neck was short and thick, and the spines in the anterior elements of the backbone were very long and formed a pronounced hump at the shoulders of the animal. *Dinohyus* was probably a root eater.

Dinornis, genus of extinct giant flightless birds that are popularly known as moas. *See* moa.

dinosaur, any member of a great series of reptiles that were the dominant land animals during most of the Mesozoic Era (from 245 to 66.4 million years ago) but became extinct at its close.

A brief treatment of dinosaurs follows. For full treatment, *see* MACROPAEDIA: Dinosaurs. The term, derived from the Greek, meaning "terrible lizard," refers to the gigantic proportions of some of these beasts. Dinosaurs belonged to two distinct but related orders—the Saurischia and the Ornithischia—that were distinguished from each other chiefly by differences in the structure of their pelvic girdles. The dinosaurs belonged to the Archosauromorpha infraclass of reptiles. Among the other archosaurs (Greek: "ruling reptiles") were the early crocodylians and extinct flying reptiles. A considerable number of dinosaurs were flesh eaters, but many others abandoned this primitive reptilian mode of life for a plant diet. The early dinosaurs may have descended from archosaurs that were bipeds; many dinosaurs remained bipedal throughout the group's history. In both dinosaur orders, however, many of the herbivore types developed a four-footed mode of locomotion.

It is believed that the saurischian dinosaurs evolved from small, bipedal archosaurs called thecodonts. Of the three known suborders of saurischians that evolved, the two main types were the theropods and the sauropods. The coelurosaurs, carnososaurs, and other theropods were all flesh eaters that walked upright on two legs. The slender-limbed, lightly built, fast-running coelurosaurs probably preyed upon smaller reptiles. They ranged from 2 to 8 feet (0.7 to 2.4 m) in length and had bird-like feet. The carnososaurs tended to reach a larger size. Among the best-known types was *Tyrannosaurus*, which had a huge skull with many sharp teeth that were highly effective biting and tearing instruments. It reached a height of about 16 to 18 feet (5 m) and a length of about 50 feet (15 m). Such an animal was powerful enough to attack any of its dinosaur contemporaries. The prosauropods evolved into the largest of all dinosaurs, the sauropods. Among these huge, four-footed plant eaters were *Diplodocus*, which reached a length of 87 feet (26 m), and the heavier *Brachiosaurus*, which weighed as much as 80 tons. Sauropods had massive bodies, powerful limbs (to support their great weight), a long tail, a long neck, and a small head.

The ornithischian dinosaurs, like the saurischians, evolved from thecodonts. The ornithischians did not grow as large as some of the saurischians but were notable for their armour and other strange adaptations. They comprised two main groups. One group, the cerapods, included the ornithopods, pachycephalosaurs, and ceratopsians. The ornithopods included the hadrosaurs and the

iguanodonts. These bipeds had ducklike mouths and several hundred teeth that they used to grind hard vegetable matter. The pachycephalosaurs were bipeds with dome-shaped skulls, while the four-footed ceratopsians, such as *Triceratops*, had a broad frill of bone protecting the head and neck and some type of long horn or horns projecting from the skull. The other main ornithischian group, the thyreophorans, included the stegosaurs and the ankylosaurs. The stegosaurs had high-arched bodies and a row of large vertical bony plates running along their backs. The ankylosaurs were heavily armoured dinosaurs with extra bone plating over most of their bodies for defensive purposes.

Most dinosaurs had long tails, but they held these tails straight out and off the ground for help in maintaining their balance, rather than dragging them along the ground as had been previously thought. Dinosaurs' means of regulating their body temperature is a continuing point of controversy. They were long thought to be ectothermic, or cold-blooded—*i.e.*, dependent on the uptake of heat from the external environment to maintain their body temperature. But recent consideration of their postures, rates of predation, and certain anatomical details has led many paleontologists to conclude that at least some dinosaurs were endothermic, or warm-blooded—*i.e.*, capable of regulating their body temperature by internal means. Contrary to the traditional image of dinosaurs as sluggish, slow-moving beasts, many of them were swift-moving creatures with relatively high metabolic rates. Most dinosaurs probably relied on a combination of endothermic and ectothermic mechanisms for thermoregulation.

Most types of dinosaurs continued to flourish until the very latest phases of the Cretaceous Period. Then, within the next million years, they disappeared completely from the geologic record, and succeeding rock strata show not the slightest trace of a dinosaur. The cause of this sudden demise is not at all clear. One widely accepted explanation for their mass extinction has been that a major geologic cycle of mountain building at the end of the Cretaceous Period reduced the lowland areas in which dinosaurs flourished and also changed the world's climate, thus stimulating evolutionary changes in the plant life upon which dinosaurs fed. A more recent theory postulates an astronomical catastrophe as the cause: a collision between an asteroid and the Earth generated a huge dust cloud that caused a period of darkness lasting as long as three years. This blockage of sunlight made photosynthesis virtually impossible, and the resulting collapse of the food chain led to the worldwide extinction of the dinosaurs and many other life forms. Although this hypothesis has been partially substantiated by geologic evidence, the apparent survival of some types of dinosaurs for as long as 1 million years after the presumed asteroid impact raises doubts that this catastrophe was the primary cause of the dinosaurs' eventual disappearance. It is possible that both climatic change and an asteroid impact played a part in the extinction of dinosaurs.

Dinosaur National Monument, area in northwestern Colorado and northeastern Utah, U.S., set aside in 1915 to preserve rich fossil beds that include dinosaur remains. The monument was enlarged from 80 acres (32 hectares) to about 328 square miles (850 square km) in 1938 and to 330 square miles (855 square km) in 1978 to protect the scenic canyons of the Green and Yampa rivers. These two rivers cut through some 20 tilted and highly coloured geologic formations of the Uinta Plateau, representing 20,000 feet (6,000 m) of strata that are exposed in deeply incised meanders. The rivers join near Steamboat Rock and flow westward as the Green.

Echo Park and Steamboat Rock, Dinosaur National Monument, Colorado

Wildlife in the area includes deer, beaver, bighorn sheep, antelope, eagles, hawks, and owls. The canyons contain evidence of prehistoric Indian life. The fossil quarry, visitor centre, a museum, nature trails, and campsites are provided for tourists.

Dinslaken, city, North Rhine-Westphalia Land (state), western Germany. It lies in the Ruhr region, about 22 miles (35 km) north of Düsseldorf. First mentioned in 1163 and chartered in 1273 by the count of Cleves (Kleve), it developed around a castle, the ruins of which now form a wing of the city's open-air theatre. Dinslaken sustained heavy damage during World War II but has been reconstructed as a modern residential city. Its varied industries include coal mining, sawmilling, and the manufacture of steel-rolling equipment, pipes, electrical equipment, nails, wire, and clothing and shoes. Pop. (1993 est.) 67,036.

Dinwiddie, Robert (b. 1693, Germiston, near Glasgow, Scot.—d. July 27, 1770, Clifton, Bristol, Eng.), British colonial administrator who as lieutenant governor of Virginia helped precipitate the French and Indian War.

After working as a merchant, Dinwiddie entered British government service in 1727 as collector of the customs for Bermuda. In 1739 he was appointed surveyor general (of revenues) for the southern part of America. In 1741 he became a member of the Governor's Council of Virginia.

Dinwiddie was appointed lieutenant governor of Virginia (in fact acting as governor, since the office of governor was a sinecure) and shortly thereafter became embroiled in a controversy with the House of Burgesses over his right to institute "pistole" fees, or taxes on land patents without the owners' consent. The Board of Trade decided the issue in favour of Virginia's lower house.

A more serious issue arose in 1753, when Dinwiddie, supporting land claims of the Ohio Company, sent George Washington to western Pennsylvania to advise the French to leave the Ohio country. Washington's mission led to a skirmish with the French the next year that, in turn, marked the onset of the French and Indian War.

In 1755 the disastrous defeat of General Edward Braddock near Fort Duquesne in Pennsylvania left Dinwiddie with the difficult task of protecting Virginia's exposed frontier settlements. He raised ranger companies and a regiment under Washington and tried continuously and vigorously to obtain intercolonial cooperation for the war effort by corresponding with various colonial officials. In 1757 Dinwiddie requested leave to return to England. He departed from Virginia on Jan. 12, 1758, to spend his last years in virtual retirement in England.

Dio (India): *see* Diu.

Dio CHRYSOSTOMUS, also called DIO COCCEIANUS, or DIO PRUSAEUS (Greek rhetorician and philosopher): *see* Dion Chrysostom.

Dio Cassius, also spelled **DION CASSIUS**, in full **CASSIUS DIO COCCEIANUS** (b. c. 150, Nicaea, Bithynia [now İznik, Tur.]—d. 235), Roman administrator and historian, the author of *Romaiika*, a history of Rome, written in Greek, that is a most important authority for the last years of the republic and the early empire.

The son of Cassius Apronianus, governor of Dalmatia and Cilicia under Marcus Aurelius, and grandson of Dio Chrysostom, Dio Cassius went to Rome (180) after his father's death and became a member of the Senate. By Macrinus he was entrusted with the administration of Pergamum and Smyrna, and on his return to Rome he was made consul. After this he obtained the proconsulship of Africa and again on his return was sent as legate successively to Dalmatia and Pannonia. He was granted a second consulship by Alexander Severus, in 229, shortly before retirement. His history of Rome consisted of 80 books, beginning with the landing of Aeneas in Italy and ending in the reign of Alexander Severus (222–235). Much of this work is preserved in later histories by Constantine VII Porphyrogenitus, John VIII Xiphilinus, and John Zonaras. Dio's industry was great, and the various offices he held gave him opportunities for historical investigation. His narratives show the hand of the practiced soldier and politician; the language is correct and free from affectation. Although, his work is far more than a mere compilation, it is not remarkable for impartiality, vigour of judgment, or critical historical faculty.

diocese, in some Christian churches, a territorial area administered by a bishop. The word originally referred to a governmental area in the Roman Empire, governed by an imperial vicar. The secular diocese was subdivided into provinces, each with its own governor; but, in the ecclesiastical adaptation of the system, the province became the larger territorial unit, administered by a metropolitan bishop and subdivided into dioceses.

The original unit of ecclesiastical administration was the parish, which in the Eastern Orthodox church still remains the designation of the area administered by the bishop, whereas the diocese is the larger area administered by the patriarch. The use of these terms was still fluid in the West in the 9th century; but, by the 13th century, diocese meant the territory administered by a bishop.

In the Roman Catholic church only the pope can divide or merge dioceses or create new ones. All dioceses are divided into parishes, each with its own church; dioceses are also sometimes divided into rural deaneries, which contain several parishes.

In the Church of England, during the 16th, 19th, and 20th centuries, new dioceses were created by statute by dividing existing ones. Each diocese is subdivided into parishes, which are grouped under rural deaneries and archdeaconries.

dioc (bird): *see* quelea.

Diocles (b. Carystus, Euboea, Greece; fl. 4th century BC), philosopher and pioneer in medicine, among Greek physicians second only to Hippocrates in reputation and ability, according to tradition.

A resident of Athens, Diocles was the first to write medical treatises in Attic Greek rather than in the Ionic Greek customarily used for such writings; only fragments of his writings survive. Usually regarded as the chief representative of the dogmatic school, he wrote on animal anatomy, dietetics, physiology, embryology, and medical botany, among other subjects. His work on animal anatomy, prepared with the aid of his work in dissection, was the first systematic textbook on the subject.

Though it was once supposed that Diocles was a contemporary of Plato (428–348/47 BC), it has been shown that he must have been

a contemporary of Aristotle (384–322 BC). His most probable dates are 375–300 BC. In doctrine, he shows a synthetic tendency, combining the influence of Hippocratic medicine and that of the Sicilian school, and his terminology and methodology suggest Aristotelian influences. Evidence exists that he had at his disposal a collection of Hippocratic writings, possibly one assembled by him. Diocles was, however, considerably more than a compiler and systematizer. Although his work in reorganizing medicine on the theoretical level was important, on the level of practical medicine he set out on original lines.

Diocletian, Latin in full **GAIUS AURELIUS VALERIUS DIOCLETIANUS**, original name **DIOCLES** (b. AD 245, Saloniae?, Dalmatia [now Solin, Croatia]—d. 316, Saloniae), Roman emperor (284–305), who restored efficient government to the empire after the near anarchy of the 3rd century. His reorganization of the fiscal, administrative, and military machinery of the empire laid the foundation for the Byzantine Empire in the East and temporarily reigned up the decaying empire in the West. His reign is

Diocletian, detail of a bust in the Capitoline Museum, Rome

Alinari—Art Resource

also noted for the last great persecution of the Christians.

Life. Diocletian's biography has been obscured by legends, rhetoric, the dubiousness of documents, and the hostility of his adversaries. Little is known of his origins. His father was a scribe or the emancipated slave of a senator called Anullinus. Diocletian's complete name, found in official inscriptions, is given as Gaius Aurelius Valerius Diocletianus. He received the name Diocles first, then the name Valerius, after the name of his daughter, Valeria, who married Galerius in 293. The gens name Aurelius did not appear until March 1, 286—that is, until after his accession. Nothing is known of his wife, Prisca, other than what the contemporary Latin Christian writer Lactantius Firmianus says in his *De mortibus persecutorum*, which is of debatable veracity. Diocles, having adopted the name Diocletianus, entered history like so many of those emperors who emerged from the shadows through force of arms, brought to power by the army. What is known of his appearance is based on coin effigies and on sculptures. From these it appears that he was tall and thin, with a large forehead, a short, strong nose, a hard mouth, and a determined chin.

Rise to power. Up to the time of his accession, Diocletian had lived most of his life in military camps. These may have been either in Gaul, as reported in the *Historia Augusta*, or in Moesia. Or he may have been a member of the Roman emperor Carinus' bodyguard. The only definite fact known about Diocletian during this period is that he was among those army chiefs whom Carinus gathered, together with the Illyrians, to fight against the Persians. In 284, during that campaign, Nu-

merian, Carinus' brother and coemperor, was found dead in his litter, and his adoptive father, the praetorian prefect Aper, was accused of having killed him in order to seize power. When Diocletian, acclaimed as emperor by his soldiers, appeared for the first time in public dressed in the imperial purple, he declared himself innocent of Numerian's murder. He designated Aper as the criminal and killed him personally. Here again, rhetoric has obscured the real events. Aper's guilt was accepted by contemporaries, but it was also true that a prediction had been made to Diocletian previously, telling him that he would become emperor on the day he killed a boar (Latin: *aper*). And it was true, too, that he did not wish to wait much longer for the boar to come. In reality, Numerian had died either a natural death or from a stroke of lightning. By eliminating Aper, however, Diocletian rid himself of an eventual competitor and, retroactively, provided his act with sacred meaning.

Acclaimed emperor on Nov. 17, 284, Diocletian possessed real power only in those countries that were dominated by his army (*i.e.*, in Asia Minor and possibly Syria). The rest of the empire was obedient to Numerian's brother Carinus. After having put down a revolt by Julianus, a troop commander in Pannonia, whom he attacked and killed near Verona, Carinus proceeded to attack Diocletian. An indecisive battle near the confluence of the Margus (modern Morava) and Danube rivers, not far from present-day Belgrade, would have been a defeat for Diocletian had Carinus not been assassinated by a group of soldiers. Thus, in midsummer of 285, Diocletian became master of the empire.

Reorganization of the empire. At the beginning of 286, Diocletian was in Nicomedia. In the interim, he and his lieutenants had calmed the stirrings of revolt among Roman troops stationed on the frontiers. From that point on, he dedicated himself to restoring civil order to the empire by removing the army from politics.

Although he came from the army's ranks, Diocletian was not, properly speaking, a soldier. He had scarcely come to power when he made an unexpected decision—to share the throne with a colleague of his choice. The empire was too great for one man to administer; nearly every week, either in Africa, or somewhere on the frontier that extended from Britain to the Persian Gulf, along the Rhine, the Danube, the Pontus Euxinus (Black Sea), and the Euphrates, he was forced to suppress a revolt or stop an invasion. Diocletian, who was more attracted to administration, required a man who was both a soldier and a faithful companion to take responsibility for military defense. In 286 he chose Maximian, an Illyrian, the son of a peasant from the area around Sirmium. A little later, though still keeping Rome as the official capital, he chose two other residences. Maximian, who was responsible for the West, was installed at Milan in northern Italy, in order to prevent German invasions. Diocletian established himself at Nicomedia, in western Anatolia and close to the Persian frontier, in order to keep watch on the East. Six years later, in 293, having taken the title of "Augustus" and given it to Maximian as well, he added two more colleagues: Galerius, a former herdsman, and Constantius I Chlorus, a Dardanian nobleman according to the legend of his house, but a rather rude countryman also. These additional collaborators were each given the title "Caesar" and attached to an Augustus, Constantius to Maximian (with a residence in Trier), and Galerius to Diocletian himself (with a residence in Sirmium).

Thus, while the empire remained a *patrimonium indivisum* (undivided inheritance), it was

nevertheless divided administratively: Diocletian, residing in Nicomedia, watched over Thrace, Asia, and Egypt; Galerius, residing in Sirmium, watched over Illyria, the Danubian provinces, and Achaëa; Maximian, residing in Milan, over Italy, Sicily, and Africa; and Constantius I Chlorus, residing in Trier, over Gaul, Spain, and Britain. In order to strengthen the union of the colleagues, each Augustus adopted his Caesar. The relationships were further cemented when Galerius married Valeria, Diocletian's daughter, and Constantius I Chlorus repudiated his wife Helena, mother of the future emperor Constantine, in order to marry Theodora, Maximian's stepdaughter. The empire now had four masters, celebrated by the authors of the *Historia Augusta* (a collection of biographies of Roman emperors and caesars, published in the 17th century) as the *quattuor principes mundi* ("four princes of the world"), and Diocletian consecrated this human unity by forming a religious bond. Because he believed that he had come to power through divine will, as revealed by the "fateful" boar, he regarded himself and Maximian as "sons of gods and creators of gods." After 287, he called himself Jovius (Jove) and Maximian was named Herculeus (Hercules), signifying that they had been chosen by the gods and predestined as participants in the divine nature. Thus, they were charged with distributing the benefits of Providence, Diocletian through divine wisdom, and Maximian through heroic energy. Later designated as *dominus et deus* on coins and inscriptions, Diocletian surrounded himself with pomp and ceremony and regularly manifested his autocratic will. Under Diocletian, the empire took on the aspects of a theocracy.

Diocletian's reforms were successful; they put an end to domestic anarchy, and elsewhere they allowed Maximian to defeat the revolt in Gaul of the Bagaudae, bands of peasants who found the tribute oppressive. Then, with peace scarcely restored after a campaign against the Germans, Maximian had to battle Carausius, who, having fought for the empire in Britain against the Frankish and Saxon pirates, revolted and named himself emperor in Britain in 287. Carausius reigned in Britain for nearly 10 years until Constantius I Chlorus succeeded in returning Britain to the empire in 296. Scarcely had troubles in Mauretania and in the Danubian regions been settled when Egypt declared itself independent under the usurper Achilleus. Diocletian reconquered the country in 296. Finally, in 297, he had to fight Narses, king of Persia, who had invaded Syria. Since he was still occupied in Egypt, he assigned this operation to Galerius, who, after a protracted campaign, finally won victory for the Romans. Tiridates, the king of Armenia and a protégé of the Romans, was able to return to his throne; the Tigris became the eastern border of the empire; and peace reigned in that part of the world until the reign of Constantine I (306–337).

Domestic reforms. Perhaps more important for the maintenance of the empire was Diocletian's program of domestic reform. He was not a complete innovator in this area, for his predecessors had made some tentative attempts in the same direction; the emperor Gallienus had excluded senators from the army and separated military from civil careers. The Senate had progressively been deprived of its privileges. Diocletian, however, systematized these arrangements in such a way that all his reforms led toward a kind of centralized and absolute monarchy that put effective means of action at his disposal. Thus, Diocletian designated the consuls; the senators no longer collaborated in the making of laws; the imperial counsellors (*consilia sacra*) were distributed

among specialized offices, and their functions were strictly defined so that the power of the praetorian prefects (personal bodyguards to the emperor) was limited; the specialization of administrative work grew; and the number of bureaucrats increased. This was the beginning of the bureaucracy and technocracy that was eventually to overrun modern societies.

Such organization made it possible for administration to rely less on individual human beings and more on the application of legal texts. In fact, it was during Diocletian's reign that the Gregorian and Hermogenian codes, of which only fragments remain, were rewritten. But 1,200 extant rescripts show another aspect of the Emperor's personality. A conservative, Diocletian was concerned with the preservation of the ancient virtues: the obligation of children to feed their parents in old age; of parents to treat their children justly; of spouses to respect the laws of marriage; of sons not to bear witness against their fathers, or slaves against their masters; and of private property, creditor's rights, and contract clauses to be protected. He forbade the use of torture if truth could be discovered otherwise and encouraged governors to be as autonomous as possible.

The army was also reorganized and brought back to the old discipline. Sedentary troops (local troops) were sent to the frontiers, and the ready army (main movable army) was made domestic. Troop strength was increased by a fourth, not multiplied by four as Lactantius claims. Here again, Diocletian's reforms were infused with a sense of human realities; he exempted soldiers from duty after 20 years of service, and, if he limited the price of commodities so as to reduce the cost of living, it was mainly to make life easier for the troops. If one is to believe Lactantius, Diocletian divided the provinces "so as to make himself more feared," but in fact it was to bring the governors closer to those they administered and, by fragmenting their power, to diminish their territorial strength. He undertook to facilitate economic development through a recovery of agriculture and a program of building.

Such policies were expensive, as were wars and the legacy of an unstable financial situation. Diocletian's fiscal solutions are still debated; they constitute a very difficult problem. Two new taxes were instituted, the *jugum* and the *capitatio*, the former being the tax on a unit of cultivable land, the latter, a tax on individuals. Taxes were levied on a proportional basis, the amount of the contribution being determined by the productivity and type of cultivation. As a rule, it was a sort of socioeconomic taxation based on the linkage between man and land in terms of either ownership or productivity. Assessments were made every five years; later, the system was consolidated into a cycle of 15 years called an *indictio*. This census of taxable adults gave rise to violent criticisms but had the theoretical advantage of replacing the arbitrary levies of the previous era. To be sure, the financial system was subject to excesses; but Diocletian's purpose was to obtain funds, and he did not even spare Italy, which had until then been free of land taxation.

This reform was accompanied by a monetary reform, including restoration of a sound gold and silver coinage of fixed design, creation of a new bronze coin, circulation of small coins to facilitate daily financial exchange, decentralization of minting, and an increase in the number of mints from 8 to 15.

All of these measures tended to stave off financial crises. The renowned Edictum de Maximis Pretiis was issued in AD 301, fixing wages and establishing maximum prices, so as to prevent inflation, abusive profits, and the exploitation of buyers. About 1,000 articles were enumerated, and violation was punish-

able by death; severe penalties were exacted of black marketeers. But even so, this regulation of prices and wages was not enforceable, and the edict was later revoked.

Persecution of Christians. The end of the reign was darkened by the last major persecution of the Christians. The reasons for this persecution are uncertain, but various explanations have been advanced: the possible influence of Galerius, a fanatic follower of the traditional Roman religion; the desire to restore complete unity, without tolerance of a foreign cult that was seen as separatist and of men who were forming a kind of state within the state; the influence of anti-Christian philosophers such as Porphyry and governors such as Hierocles on the scholarly class and on the imperial court; the fear of an alienation of rebellious armies from emperor worship; or perhaps the disturbances provoked by the Christians themselves, who were agitated by doctrinal controversies. At any rate, some or all of these factors led Diocletian to publish the four edicts of 303–304, promising all the while that he would not spill blood. His vow went unheeded, however, and the persecutions spread through the empire with an extreme violence that did not succeed in annihilating Christianity but caused the faith of the martyrs to blaze forth instead.

Assessment. Diocletian had aged prematurely through illness. Perhaps he decided that, after 20 years of reign, his abdication was also "fateful." Of his own volition he decided to entrust the affairs of the empire to younger men and returned first to Nicomedia, then to the neighbourhood of Salona, on the edge of the Adriatic, where he had a magnificent palace built (the modern town of Split, in Yugoslavia, occupies the site of its ruins). He abdicated May 1, 305, and his death occurred almost unnoticed.

Diocletian had reorganized the empire without political romanticism. His reforms had not proceeded from a premeditated plan but had imposed themselves out of historical necessity. He may be accused of several things: of having been cruel, but his harshness was not the act of deep-seated brutality; of being miserly, but this miserliness was inspired by the desire to obtain resources for the state; of cutting a slightly muddle-headed, visionary figure, but these were the traits that led him to reflect on better methods of governing an immense territory; of having paved the way to bureaucracy and technocracy, but this was done with greater efficiency in view. Personally, Diocletian was a religious man. No doubt he did not manifest any unusual piety, but he always thought that the gods of the emperors governed the world. He exercised an absolute, "divine right" monarchy, and he surrounded it with an almost Oriental majesty.

Partially he failed in his task, and one can rightly say that the state he created was not "the new house he intended to build, but rather an emergency shelter," which offered protection against storms with the help of the gods. The fact remains that he was, in his actions, his religion, and his time, *vir rei publicae necessarius*, "the man whom the State needed." (Je.C.)

Diocletian, Palace of, ancient Roman palace built between AD 295 and 305 at Split (Spalato), Croatia, by the emperor Diocletian as his place of retirement (he renounced the imperial crown in 305 and then lived at Split until his death in 316). It was both an imperial city-palace and a sea fortress, as well as a country house of vast proportions and magnificence, covering an area of 9½ acres (four hectares). The north to south wall measured 705 feet (215 metres), with the walls being 7 ft thick and 72 ft high on the Adriatic side and 60 ft on the north. There were 16 towers and four gates: Porta Aurea (north), Porta Argentea (east), Porta Ferrea (west), and Porta Aenea (south). The rectangular ground plan was like a Roman camp; *i.e.*, with four arcaded avenues 36 ft wide meeting in the middle. The imperial apartments were in the two southern quadrants, along the width of which ran a 524-ft-long and 24-ft-wide arcaded grand gallery (probably for promenades and display of art) that was open to scenic views of the sea and the Dalmatian coast. The Temple of Jupiter and Diocletian's mausoleum (a cathedral after the 7th century) were located in courts of the imperial section. Guests and household officials were accommodated in the northern quadrants.

The Avars badly damaged the palace, but when their incursion was over (639) the inhabitants of the ruined city of Salona (Salonae; Diocletian's birthplace) took refuge within what remained of the palace and built their homes, incorporating the old walls, columns, and ornamentation in their new structures (this area is now the "Old Town" of Split).

Diocletian window, window with a somewhat rounded top, or head, and bronze-framed panes of glass, named after those in the palace of the 3rd-century Roman emperor Diocletian at Spalato (Split, Croatia) and in the Baths of Diocletian, Rome (now the church of Sta. Maria degli Angeli). The window was used again in the 16th century, especially by Andrea Palladio, and in the late 18th century by Robert Adam.

Diodati, Giovanni (b. June 6, 1576, Lucca, Italy—d. Nov. 3, 1649, Geneva), Swiss Calvinist pastor known for his translation of the Bible into Italian.

Born of a refugee Protestant family from Lucca, Diodati became a pastor at Geneva in 1608 and professor of theology in 1609. A leader of the Reformers, he was an eloquent, bold, and fearless preacher and a rigid Calvinist. He conducted a mission to France in 1614 and was appointed to record the proceedings of the Synod of Dort (1618–19). His Italian translation of the Bible was first published in 1603. He was also the author of a translation into French and of biblical annotations and polemical treatises.

diode, electron tube, evacuated glass or metal envelope containing two electrodes, a cathode and an anode. It is used as a rectifier and as a detector in electronic circuits such as radio and television receivers. When a positive voltage is applied to the anode (or plate), electrons emitted from the heated cathode flow to the plate and return to the cathode through an external load. If a negative voltage is applied to the plate, electrons cannot escape from the cathode and no plate current flows. Thus a diode permits electrons to flow from the cathode to the plate, but not from plate to cathode. If an alternating voltage is applied to the plate, current flows only during the time when the plate is positive. The alternating voltage is said to be rectified, or converted to dc (direct current).

In the indirectly heated cathode type of tube shown in the illustration, the electron emitter consists of a metallic cylinder, usually nickel, coated with an electron emitter, such as a mixture of barium and strontium oxides. The

Diode

heat is provided by a coil of wire (heater) located inside the sleeve but insulated from it. In the directly heated cathode (right), the heater wire itself serves as the source of electrons and is referred to as the filament.

Solid-state rectifiers, which have largely replaced the vacuum type, are also frequently referred to as diodes.

Diodorus CRONUS (b. Iasus, Caria, Anatolia; fl. 4th century BC), philosopher of the Megarian school, remembered for his innovations in logic. His surname Cronus, of uncertain meaning, was applied both to him and to his teacher, the philosopher Apollonius of Cyrene. Through Apollonius he is linked with Eubulides of Miletus, a 4th-century Greek thinker; together the three men formed the branch of the Megarian school that was especially strong in formal logic. The 3rd-century-AD historian Diogenes Laërtius reported that, at the court of Ptolemy Soter, Diodorus could not solve a logical problem propounded by Stilpon and died of shame at his failure (c. 307). None of Diodorus' writings are extant.

Diodorus Siculus (fl. 1st century BC, Agyrium, Sicily), Greek historian, the author of a universal history, *Bibliotheca historica*.

Diodorus lived in the time of Julius Caesar and Augustus, and his own statements make it clear that he travelled in Egypt during 60–57 BC and spent several years in Rome. The latest event mentioned by him belongs to the year 21 BC. His history consisted of 40 books and was divided into three parts. The first treats of the mythic history of the non-Hellenic and Hellenic tribes to the destruction of Troy; the second ends with Alexander's death; and the third continues the history as far as the beginning of Caesar's Gallic War. The *Bibliotheca*, invaluable where no other continuous historical source has survived, supplies to some extent the loss of the works of earlier authors, from which it was compiled. Diodorus does not always quote his authorities, but in the books that have survived his most important sources for Greek history were certainly Ephorus (for 480–340 BC) and Hieronymus of Cardia (for 323–302).

Diodotus I (fl. mid-3rd century BC), satrap (governor) of the Seleucid province of Bactria,

Diodotus I, coin, 3rd century BC

By courtesy of the trustees of the British Museum, photograph, J.R. Freeman & Co. Ltd.

who, with his son of the same name, founded the Greek kingdom of Bactria.

At first subject to the Seleucid king Antiochus I and later to Antiochus II, Diodotus rebelled in about 250 and took the title of king. Little is known of his reign, but, according to some scholars, the Seleucid king Seleucus II, in order to secure Diodotus' friendship, married one of his sisters to him during a time (246) when the Seleucid Empire was in chaos. Diodotus was succeeded by his son, Diodotus II, and after his death was called by the cult-name Soter (Saviour).

Diodotus II (fl. late 3rd century BC), king of Bactria, the son and successor of Diodotus I.

Although his father's freedom from Seleucid control is uncertain, Diodotus II unquestionably ruled as an independent king and issued coinage in his own name. He further proclaimed the independence of the kingdom of Bactria by entering into an alliance with the Parthians against Seleucus II, in contrast with his father's friendly policy toward the Seleucid Kingdom. At an uncertain date (perhaps c. 235), Diodotus II was overthrown by the usurper Euthydemus.

Diogenes (b. Sinope, Paphlagonia—d. c. 320 BC, probably at Corinth, Greece), archetype of the Cynics, a Greek philosophical sect that stressed stoic self-sufficiency and the rejection of luxury. He is credited by some with originating the Cynic way of life, but he himself acknowledges an indebtedness to Antisthenes, by whose numerous writings he was probably influenced. It was by personal example rather than any coherent system of thought that Diogenes conveyed the Cynic philosophy. His followers positioned themselves as watchdogs of morality.

Diogenes is the subject of numerous apocryphal stories, one of which depicts his behaviour upon being sold into slavery. He declared that his trade was that of governing men and was appointed tutor to his master's sons. Tradition ascribes to him the famous search for an honest man conducted in broad daylight with a lighted lantern. Almost certainly forced into exile from Sinope with his father, he had probably already adopted his life of asceticism (Greek *askesis*, "training") when he reached Athens. Referred to by Aristotle as a familiar figure there, Diogenes began practicing extreme anti-conventionalism. He made it his mission to "deface the currency," perhaps meaning "to put false coin out of circulation." That is, he sought to expose the falsity of most conventional standards and beliefs and to call men back to a simple, natural life.

For Diogenes the simple life meant not only disregard of luxury but also disregard of laws and customs of organized, and therefore "conventional," communities. The family was viewed as an unnatural institution to be replaced by a natural state in which men and women would be promiscuous and children would be the common concern of all. Though Diogenes himself lived in poverty, slept in public buildings, and begged his food, he did not insist that all men should live in the same way but merely intended to show that happiness and independence were possible even under reduced circumstances.

The program for life advocated by Diogenes began with self-sufficiency, or the ability to possess within oneself all that one needs for happiness. A second principle, "shameless-

ness," signified the necessary disregard for those conventions holding that actions harmless in themselves may not be performed in every situation. To these Diogenes added "outsokenness," an uncompromising zeal for exposing vice and conceit and stirring men to reform. Finally, moral excellence is to be obtained by methodical training, or asceticism.

Among Diogenes' lost writings are dialogues, plays, and the *Republic*, which described an anarchistic utopia in which men lived "natural" lives. Diogenes' life and philosophy are studied in Ragner Höistad's *Cynic Hero and Cynic King* (1949).

Diogenes LAËRTIUS (fl. 3rd century), Greek author noted for his history of Greek philosophy, the most important existing secondary source of knowledge in the field. One of its traditional titles, *Peri biōn dogmatōn kai apophthegmatōn tōn en philosophia eudokimēsautōn* ("Lives, Teachings, and Sayings of Famous Philosophers"), indicates its great scope. The work is a compilation, the excerpts of which range from insignificant gossip to valuable biographical and bibliographical information, competent summaries of doctrines, and reproductions of significant documents such as wills. Though he quoted hundreds of authorities, he knew most of them only by second hand; his true sources have not been ascertained except in a few cases. The work itself consists of an introductory book and nine others presenting Greek philosophy as divided into an Ionian and an Italic branch (books ii-vii; viii) with "successions," or schools, within each and with "stray" philosophers appended (books ix-x). In all extant manuscripts, the oldest of which belongs to the 12th century, part of book vii is missing.

Diogenes OF APOLLONIA (fl. 5th century BC), Greek philosopher remembered for his cosmology and for his efforts to synthesize ancient views and new discoveries.

It is uncertain whether Diogenes' birthplace, from which his name is derived, was the Apollonia of Crete or that of Phrygia (in modern Turkey). He lived most of his life in Athens, where his opinions were a source of danger to his life and were derided by the playwright Aristophanes in his *Nephelai* ("The Clouds"). Among numerous fragments of his works, written in Ionic Greek, is the important book *Peri physeōs* ("On Nature"). The treatise *Against the Sophists* and the *Nature of Man* may have been part of this work. Aristotle, in his *Historia animalium* ("The History of Animals"), quotes a long passage from Diogenes on veins. Because Diogenes sought to support his metaphysical position by painstaking observations in anatomy and physiology, he is sometimes considered to be one of the early Empiricists.

Diogenes, Lamp of (monument): see choragic monument.

Diognetus, Letter to, an early Christian apologetic work probably dating from the 2nd or 3rd century AD. It is often included with the works of the Apostolic Fathers, Greek Christian writers of the late 1st and early 2nd centuries, but it more accurately is associated with the early Apologists (primarily 1st century). Both the person addressed and the author of the work are unknown, although at one time the apologist Justin Martyr was erroneously considered the author. The work survived antiquity in one 13th-14th-century manuscript, which was destroyed by fire in Strasbourg, Fr., in 1870.

The first 10 chapters of the letter discuss pagan and Jewish religions, the life of a Christian as contrasted with the life of a non-Christian, and a review of the Christian faith as the unique revelation of God. The final two chap-

ters, a sermon, were evidently written by a different author, also unknown.

Diomede Islands, Russian OSTROVA GVOZDEVA, two small islands in the Bering Strait, lying about 2½ mi (4 km) apart and separated by the U.S.-Russian boundary, which coincides with the International Date Line. The larger island, Big Diomede (Russian Ostrov Ratmanova [Ratmanov Island]), has an area of 4 sq mi (10 sq km) and is part of the Chukchi autonomous okrug, in Russia. It has no permanent population but is the site of an important Russian weather station. To the east lies Little Diomede Island, a part of Alaska, inhabited by maritime Chukchi people. The islands' first European visitor was the Danish navigator Vitus Jonassen Bering on Aug. 16 (St. Diomede's Day), 1728.

Diomedes, in Greek legend, commander of 80 Argive ships and one of the most respected leaders in the Trojan War. His famous exploits include the wounding of Aphrodite, the slaughter of Rhesus and his Thracians, and seizure of the Trojan Palladium, the sacred image of the goddess Pallas Athena that protected Troy. After the war Diomedes returned home to find that his wife had been unfaithful (Aphrodite's punishment) and that his claim to the throne of Argos was disputed. Fleeing to Italy he founded Argyripa (later Arpi) in Apulia, eventually making peace with the Trojans. He was worshipped as a hero in Argos and Metapontum. According to Roman sources, his companions were turned into birds by Aphrodite, and, hostile to all but Greeks, they lived on the Isles of Diomedes off Apulia.

Dion (b. c. 408 BC—d. 354), brother-in-law of Dionysius the Elder, tyrant of Syracuse, in Sicily, and master of Syracuse intermittently between 357 and 354.

When the younger Dionysius, who was weak and inexperienced, succeeded in 367, Dion assumed control and persuaded Plato, whose friendship he had acquired, to train the new tyrant in the practical application of his philosophical principles. The experiment failed and Dion was banished, but in 357, assembling a force of 1,500 mercenaries at Zacynthus, he sailed to Sicily and was received with demonstrations of joy. After a short period of rule he was again banished and again recalled. In 354 he was assassinated. He was included by Plutarch in his *Lives*.

Dion CHRYSOSTOM, Greek DION CHRYSOSTOMOS ("golden-mouthed"), Latin DIO CHRYSOSTOMUS; also called DIO PRUSAENSIS, or DIO COCCIANUS (b. c. AD 40, Prusa, Bithynia—d. c. 112), Greek rhetorician and philosopher who won fame in Rome and throughout the empire for his writings and speeches.

Dion was banished in AD 82 for political reasons from Bithynia and Italy. He wandered for 14 years through the lands near the Black Sea, adopting the life of poverty advocated by the Cynics. With the death of the emperor Domitian his exile ended, and he made a new career as an orator and philosopher.

A collection of 80 "orations" with fragments of others survives, but some are dialogues or moral essays, and two are spurious. Four are speeches addressed to Trajan. In *Olympicus* the sculptor Phidias explains the principles he followed in his famous statue of Zeus, one passage being supposed by some to have suggested the German dramatist Gotthold Lessing's *Laocoon*. In *On Aeschylus, Sophocles and Euripides*, Dion compares the treatment of the story of Philoctetes by each tragedian. Best known is the *Euboicus*, depicting country life on the island of Euboea, an important document for social and economic history. A patriotic Greek who accepted Roman rule, Dion typifies the revival of Greek self-confidence under the Roman Empire that marks the beginning of the new or second sophistic movement in the 2nd century AD.

Dione, in Greek mythology, a consort and, in one remote region, cult partner of Zeus, the king of the gods. Since the partner and wife of Zeus was normally the goddess Hera, it has been conjectured that Dione is an older figure than Hera. Dione was variously described. In the *Iliad* she is mentioned as the mother of the goddess Aphrodite by Zeus; in Hesiod's *Theogony*, however, she is simply identified as a daughter of Oceanus. Other writers have identified her as the mother of Dionysus.

Dione, fourth nearest of the major regular moons of Saturn. It was discovered by the Italian-born French astronomer Gian Domenico Cassini in 1684.

Dione has a diameter of 1,120 km (696 miles) and revolves around Saturn at a mean distance of 377,400 km (234,500 miles), which is within the outer part of Saturn's tenuous E ring. Two much smaller moons, Helene and Polydeuces, travel in Dione's orbit, maintaining stable mean positions 60° ahead of and behind Dione, respectively (cf. Trojan planets).

Dione rotates synchronously with its orbital motion, always leading with the same hemisphere in orbit. Its surface shows great brightness contrasts, with the trailing side generally darker than the leading one. On average, however, Dione is highly reflective, indicative of a surface largely of geologically fresh water ice. The moon's low density—1.5 times that of water—suggests a composition of about equal amounts of ice and rock. Dione is covered in places with impact craters, mostly on the leading side. Their density and size distribution suggest a geological age close to four billion years. Areas with fewer craters may have undergone melting and resurfacing. It is also possible that Dione's surface is continually coated by new ice particles from the E ring.

Dione's trailing side is broken by many bright linear features, some associated with troughs and ridges, that form a polygonal network. Wispy features seen in Voyager spacecraft images had been thought to be deposits of material that erupted from Dione's interior along linear fractures. Higher-resolution images from the Cassini spacecraft, however, show no evidence of such activity.

Dione is involved in an orbital resonance—i.e., its 66-hour trip around Saturn is twice that of the nearer moon Enceladus (*q.v.*). This relationship has been proposed as a source of the dramatic tidal heating seen in Enceladus.

Dionne QUINTUPLETS, the five daughters—Émilie, Yvonne, Cécile, Marie, and Annette—born prematurely on May 28, 1934, near Callander, Ont., Can., to Oliva and Elzire Dionne. The parents had 14 children, 9 by single births. The quintuplets became international celebrities during their early years—making three feature films for Twentieth Century Fox and providing profitable endorsements for products from cod-liver oil to typewriters and automobiles. The attending physician, Allan Roy Dafeo (d. 1941), also became a celebrity. In 1935 Ontario made the quintuplets wards of the government, and Dafeo became their primary caretaker. A hospital was built for them to live in, and "Quintland," as it was known, became a popular tourist destination. Their father regained custody in 1941; in 1998 the sisters successfully sued the government for separating them from their parents.

The "quints" were remarkable in being the first medically and genetically documented set that survived; not one member of any other quintuplet set had previously lived more than a few days. The Dionne set had a sixth member that aborted during the third month of pregnancy. Much credit for the survival of the five premature infants was owing to the Hospital for Sick Children, Toronto, which quickly made available to Dafeo quantities of mother's milk and modern incubators and other equipment.

The University of Toronto conducted biological, psychological, and dental studies of the quintuplets. The biological study established that the set originated from one fertilized egg. The Dionne quintuplets arose through repeated twinning of the early single embryo; therefore, six embryos were produced, and the five infants surviving birth inherited the same genetic material.

Three of the sisters married: Annette had three sons; Marie had two daughters; and Cécile had four sons and one daughter. Only Cécile had a multiple birth: twin sons, one of whom died at the age of 15 months.

Émilie died of an epileptic seizure on Aug. 6, 1954, at Sainte-Agathe-des-Monts, Que.; Marie died in Montreal on Feb. 27, 1970; Yvonne died on June 23, 2001, in Montreal. In their memoirs *We Were Five* (1964) and *Family Secrets: The Dionne Quintuplets* (1994), the sisters describe the exploitation they endured as children.

Dionysia (Greco-Roman religion): see Bacchalia.

Dionysian period, also called GREAT PASCHAL PERIOD, or VICTORIAN PERIOD, in calendars, a period of 532 years covering a complete cycle of New Moons (19 years between occurrences on the same date) and of dominical letters—*i.e.*, correspondences between days of the week and of the month, which recur every 28 years in the same order. The product of 19 and 28 is the interval in years (532) between recurrences of a given phase of the Moon on the same day of the week and month. This period is called Victorian for the astronomer Victorius of Aquitaine, its first calculator (c. AD 465); Dionysian for Dionysius Exiguus, who revised Victorius' figures in the 6th century; and Great Paschal because of its use in determining the date of Easter.

Dionysius BAR-SALIBI: see Bar-Salibi, Jacob.

Dionysius EXIGUUS, English DENIS THE LITTLE (fl. early 6th century AD), celebrated 6th-century canonist who is considered the inventor of the Christian calendar, the use of which spread through the employment of his new Easter tables.

The 6th-century historian Cassiodorus calls him a monk, but tradition refers to him as an abbot. He arrived in Rome about the time of the death (496) of Pope St. Gelasius I, who had summoned him to organize the pontifical archives. Thereafter, Dionysius flourished as a scholar at Rome. In 525, at the request of Pope St. John I, he prepared the chronology still current; it was a modified Alexandrian computation (95-year tables evolved by the patriarch Theophilus of Alexandria) based on Victorius of Aquitaine's 532-year cycle. He wrongly dated the birth of Christ according to the Roman system (*i.e.*, 754 years after the founding of Rome) as Dec. 25, 753.

Highly reputed as a theologian and as an accomplished mathematician and astronomer, Dionysius was well versed in the Holy Scriptures and in canon law. Credited to him are a collection of 401 ecclesiastical canons—including the apostolic canons and the decrees of the councils of Nicaea, Constantinople, Chalcedon, and Sardis—and a collection of the decretals of the popes from St. Siricius (384–399) to Anastasius II (496–498). Dionysius also translated many Greek works now lost, including a life of St. Pachomius and an instruction of St. Proclus of Constantinople.

Dionysius OF ALEXANDRIA, SAINT, also called SAINT DIONYSIUS THE GREAT (b. c. 200, Alexandria—d. c. 265, Alexandria; feast day November 17), bishop of Alexandria, then the most important Eastern see, and a chief opponent of Sabellianism (*q.v.*).

A Christian convert, Dionysius studied in Alexandria at the catechetical school headed

by Origen, whom in 231/232 he was elected to succeed. In 247/248 he became bishop of Alexandria. During the persecution (250–251) of Christians by the Roman emperor Decius, Dionysius fled to the Libyan Desert, and he was again exiled in the Valerian persecution (257–260).

On his return to Alexandria in about 260, Dionysius favoured readmitting penitent apostates to the church in opposition to those who wanted to exclude them permanently. Engaged in the bitter controversy over baptism performed by heretics, Dionysius did not insist on rebaptizing converts who had received heretical baptism, but he recognized the right of communities to rebaptize if they preferred. He denied that the Book of Revelation was written by St. John the Evangelist and denounced the Millenarians, who, basing their argument on a literal reading of Revelation, believed that after 1,000 years Jesus Christ would return and establish his kingdom on Earth.

Dionysius was especially noted for his attacks on the Sabellians, who accused him of separating the persons of the Trinity (tritheism) and other heresies. Protests were sent to Pope St. Dionysius in Rome, who condemned those who denied any distinction between the persons of the Trinity and those who acknowledged three separate persons. Dionysius of Alexandria accepted the pope's judgment and repudiated the Sabellians' charges, but he insisted that the Trinity consisted of three inseparable persons. His position has since been vindicated by the church.

Dionysius also wrote a treatise on nature against the atomism of the Greek philosopher Epicurus. Though highly esteemed and often cited by the leading Byzantine theologians, his works are known only from quotations, many of them extensive, preserved by Bishop Eusebius of Caesarea and other writers.

Dionysius OF HALICARNASSUS, Greek DIONYSIOS (fl. c. 20 BC; b. Halicarnassus, Caria, Asia Minor), Greek historian and teacher of rhetoric whose history of Rome, from its origins to the First Punic War, written from a pro-Roman standpoint but carefully researched, is, with Livy's, the most valuable source for early Roman history.

Dionysius migrated to Rome in 30 BC, and his history, which sought to justify the Romans to the Greeks, began to appear in 7 BC. Of its 20 books, only the first 10 are extant. His literary and rhetorical theories are propounded in several extant treatises: *On Imitation* (containing assessments of individual authors), *Commentaries on the Ancient Orators*, and *On the Arrangement of Words*, the only surviving ancient study of the principles of word order and euphony.

Dionysius, SAINT (b. Greece?—d. Dec. 26, 268, Rome; feast day December 6), pope from July 22, 259, to Dec. 26, 268.

While a presbyter during the pontificate of Pope Stephen I (254–257), he took part in the controversy on rebaptism of converts and received an appeal from Dionysius, bishop of Alexandria, to avoid a break between Rome and the Asian churches.

Dionysius, who succeeded Sixtus II as pope, faced the urgent task of reorganizing the church. Sixtus had been martyred in the persecution of Christians under the emperor Valerian. The see of Rome had been vacant for almost a year. One of Dionysius' first acts was to send funds to the Christians in Cappadocia (in modern Turkey) suffering from a Persian invasion (259). In response to charges of tritheism—*i.e.*, separating the members of the Trinity as three distinct deities—against Bishop Dionysius of Alexandria, the pope convened a Roman synod (260) and demanded an explanation from Bishop Dionysius; this became known as "the affair of the two Dionysii." Semantics was at the root of the dif-

ficulty; Greek and Roman understandings of the same terms differed. The discussions at the synod helped to prepare the way for the theology of the Nicene Creed (325). The bishop cleared himself in his *Refutation and Apology* and accepted the pope's authority. Thus the Roman Church's claim to governing in matters of faith was strengthened by Dionysius' pontificate.

Dionysius TELMAHARENSIS, also called DIONYSIUS OF TELL MAHRE (d. Aug. 22, 845), patriarch of the Syrian Jacobite church and author of an important source document on Eastern Christianity between the reigns of the Byzantine emperors Maurice (582–602) and Theophilus (829–842).

After some years as a monk in Syria, Dionysius was chosen patriarch and ordained a priest in 818 in the Jacobite church, which took its name from Jacob Baradaeus. Although Dionysius' position was contested by a rival schismatic group during his entire reign, he succeeded in effectively governing the Syrian community. Through cordial relations with the Muslim rulers, Dionysius prevented violent suppression of the Syrian Christians and sacking of their property. The persecution, however, resumed toward the end of his life.

Dionysius' chronicles, although uncritical and only partly preserved in manuscript, retain their value as source data on life in the premedieval Syrian church. They were included in subsequent Syriac annals and contributed a distinctive stage in the development of its literary culture.

Dionysius THE AREOPAGITE (fl. 1st century AD), biblical figure, converted by St. Paul at Athens (Acts 17:34), who acquired a notable posthumous reputation primarily through confusion with later Christians similarly named. In the 2nd century he was held to have been the first bishop of Athens, and in the 9th century he was identified with St. Denis of France. In about 500, probably in Syria, some writings were forged in his name by a Christian Neoplatonist with moderate Monophysite leanings. These writings, whose author is often referred to as Pseudo-Dionysius, became of decisive importance for the theology and spirituality of Eastern Orthodoxy and Western Catholicism. (See also Pseudo-Dionysius the Areopagite.)

Dionysius THE CARTHUSIAN, Flemish DENYS VAN LEEUWEN, or DE LEEUWEN, also called DENYS RYCKEL, or VAN RIJEL (b. 1402/1403, Rijkel, Lower Lorraine, Holy Roman Empire [now in Belgium]—d. March 12, 1471, Roermond, Lower Lorraine [now in The Netherlands]), theologian and mystic, one of the important contributors to, and propagators of, the influential school of Rhenish spirituality originating in the 14th century.

Educated at the University of Cologne, Dionysius entered the Carthusian order at the charterhouse of Roermond, in 1425. In 1451–52 he accompanied Nicholas of Cusa, papal legate to northern Germany and the Netherlands, on a mission for church reform in the Rhineland. In charge of the Carthusians at 's Hertogenbosch from 1465, he retired in 1469 because of poor health.

The school of Rhenish spirituality was influenced by Neoplatonism, the theology of St. Thomas Aquinas, and the teaching of Pseudo-Dionysius, whose works especially inspired late medieval mystics. Dionysius used Aquinas, Pseudo-Dionysius, and the Dutch mystic Jan van Ruysbroeck as principal authorities in writing his classic, *De contemplatione*. For Dionysius, mystical contemplation was an infusion of the gift of wisdom by the Holy Spirit, for which the soul could be prepared by the renunciation of all save God.

A prolific writer on dogmatic, ascetical, and mystical theology, he also sent letters to rulers calling for a crusade against the Turks, wrote treatises on church reformation, and compiled commentaries on Scripture and Pseudo-Dionysius, a compendium on Aquinas' *Summa*, and a handbook of philosophy. His commentaries and treatises were particularly popular in the 16th century. Dionysius' *Opera Omnia* were published (1896–1935) in 42 volumes.

Dionysius THE ELDER (b. c. 430 BC—d. 367), tyrant of Syracuse from 405 who, by his conquests in Sicily and southern Italy, made Syracuse the most powerful Greek city west of mainland Greece. Although he saved Greek Sicily from conquest by Carthage, his brutal military despotism harmed the cause of Hellenism.

After working as a clerk in a public office, Dionysius distinguished himself fighting in the war with Carthage that broke out in Sicily in 409. He took advantage of a crisis in the war to make himself tyrant in 405. Over the next eight years he ruthlessly consolidated and expanded his power. He built a wall around Syracuse and fortified Epipolae. The Greek citizens of Naxos, Catania, and Leontini were removed from their cities; many of them were enslaved and their homes were given to Sicilian and Italian mercenaries.

Dionysius was then ready to lead his vast army against Carthage, which had occupied western and southern Sicily. His first war with Carthage (397–396), during which the Greeks besieged Motya and the Carthaginians Syracuse, ended with a notable victory for Dionysius, who confined his enemy's power to an area of northwest Sicily. A second conflict ended in 392 with a treaty advantageous to Dionysius. After 390 he led an expedition against Rhegium and other Greek cities of southern Italy, and with the aid of the Lucanians he devastated the territories of Thurii, Croton, and Locri. By the time Rhegium fell (386), Dionysius had become the chief power in Greek Italy. He sent colonists to Illyria and possibly to northeast Italy. Although the Athenian writer Isocrates hailed him as a champion of Hellenism, the brutality of Dionysius' conquests made him unpopular in Greece, and his literary pretensions were deplored. When he sent a splendid embassy to the Olympic festival of 388, a crowd pillaged the tents of his envoys.

Dionysius' third war with Carthage (383–c. 375) proved disastrous; he suffered a crushing defeat at Cronium and was forced to pay an indemnity of 1,000 talents and cede the territory west of the Halycus River. Nevertheless, he was engaged in yet another conflict with the Carthaginians at the time of his death.

Dionysius THE GREAT, SAINT: see Dionysius of Alexandria.

Dionysius THE YOUNGER, ruler of Syracuse, in Sicily, 367–357 and 346–344 BC.

Dionysius was the son and successor of Dionysius the Elder, but he lacked the vigour to maintain the military autocracy he had inherited. Upon his accession in 367 he made peace with Carthage on the same unfavourable terms established after his father's defeat in the third war with Carthage (383–c. 375). Dion, a former minister, tried with Plato to make a philosopher-prince of Dionysius, but both counsellors were dismissed in 366. In 357 Dion drove Dionysius from his kingdom, and the deposed ruler fled to Locri. In 346, some eight years after the assassination of Dion, Dionysius regained control of Syracuse. On the arrival of the Greek general Timoleon from Corinth two years later, Dionysius was compelled to surrender and retire to Corinth.

Dionysius Longinus: see Longinus.

Dionysus, also called **BACCHUS**, or (in Rome) **LIBER**, in Greco-Roman religion, a nature god of fruitfulness and vegetation, especially known as a god of wine and ecstasy. Though introduced from Thrace and Phrygia, the strange legends of his birth and death and his marriage to Ariadne, in origin a Cretan god-

Dionysus, classical bas-relief sculpture, in the Museo Archeologico Nazionale, at Naples
Alinari—Art Resource/EB Inc

dess, suggest that his cult represented a reversion to pre-Hellenic Minoan nature religion.

According to the most popular tradition, Dionysus was the son of Zeus and Semele, a daughter of Cadmus (king of Thebes), but in origin a Phrygian earth goddess. Hera, the wife of Zeus, out of jealousy persuaded Semele to prove her lover's divinity by requesting him to appear in his real person. Zeus complied, but his power was too great for the mortal Semele, who was blasted with thunderbolts. Zeus, however, saved his son by sewing him up in his thigh, keeping him there until he reached maturity, so that he was twice born. Dionysus was then conveyed by the god Hermes to be brought up by the Bacchantes (Maenads, or Thyiads) of Nysa, a purely imaginary spot.

As Dionysus apparently represented the sap, juice, or lifeblood element in nature, lavish festal *orgia* (rites) in his honour were widely instituted. These Dionysia (Bacchanalia, *q.v.*) quickly won converts among the women in the post-Mycenaean world. The men, however, met it with hostility. According to tradition, Pentheus, king of Thebes, was torn to pieces by the Bacchantes when he attempted to spy on their activities, while the Athenians were punished with impotence for dishonouring the god's cult. The women, nevertheless, abandoned their families and took to the hills, wearing fawn skins and crowns of ivy and shouting "Euoi!" the ritual cry. Forming *thyasi* (holy bands) and waving *thyrsoi* (fennel wands bound with vine leaves and tipped with ivy), they danced by torchlight to the rhythm of the flute and the *tympanon* (kettledrum). While they were under the god's inspiration, the Bacchantes were believed to possess occult powers, the ability to charm snakes and suckle animals, as well as preternatural strength that enabled them to tear living victims to pieces before indulging in a ritual feast (*omophagia*). The Bacchantes hailed the god by his titles of Bromios (Thunderer), Taurokeros (Bull-

Horned), or Tauroprosopos (Bull-Faced), in the belief that he incarnated the sacrificial beast. The worship of Dionysus flourished long in Asia Minor, particularly in Phrygia and Lydia, and his cult was closely associated with that of numerous Asiatic deities.

Although Dionysus was believed to have descended to the underworld to bring back his mother Semele and was also associated with Persephone in southern Italy, any original connection between the god and the netherworld seems doubtful. Dionysus did, however, possess the gift of prophecy, and at Delphi he was received by the priesthood on almost equal terms with Apollo. He had an oracle in Thrace and was later patron of a healing shrine at Amphicleia in Phocis.

The followers of Dionysus included spirits of fertility, such as the satyrs, and in his ritual the phallus was prominent. He often took on a bestial shape and was associated with various animals. His personal attributes were an ivy wreath, the thyrsus, and the kantharos, a large two-handled goblet. In early art he was represented as a bearded man, but later he was portrayed as youthful and effeminate. Bacchic revels were a favourite subject with vase painters, though the private lodges of Bacchus were rigorously suppressed throughout Italy by senatorial edict in 186 BC.

Dionysus, Theatre of, prototype of Greek theatres, situated on the south side of the Acropolis in Athens, in which all extant classical Greek plays were first presented. Development on the site began with the creation of the orchestra, a circular floor of earth 60 feet in diameter with an altar at the centre. Placed adjacent to temples of nature and of the fertility god Dionysus, the orchestra was used for dramatic performances, which, together with a procession and sacrifice, composed the annual spring festival of the god. During the 5th century BC, the theatre served as the locus of the contests in which the plays of Sophocles, Euripides, Aeschylus, and Aristophanes (which developed from the Dionysian tradition) were first performed. At the time, the auditorium, perhaps with wooden benches, was set into the hillside, and the skene, or building serving as the background of the play, was built on the opposite side of the orchestra.

In the mid-4th century BC, raked tiers of stone seats capable of accommodating as many as 17,000 spectators were constructed, as well as an enhanced stone skene. Major revisions, probably including the introduction of a raised stage, were carried out in c. AD 61 under the Roman emperor Nero. After the 4th century the theatre fell into disuse and decay. It was rediscovered in 1765, and major archaeological restoration was undertaken in the late 1800s under archaeologist and Greek architectural authority Wilhelm Dörpfeld.

Dioon, a New World genus of ornamental cycads (plants of the family Cycadaceae). It

Dioon edule
Walter Dawn

is the most primitive American genus in the family and includes four or more species. The spiny-leaved, slow-growing giant dioon (*D. spinulosum*) may attain a height of 15 m (about 50 feet). It is a popular house plant. Starch like that of arrowroot is obtained from the seeds of *D. edule*.

Diop, Birago (b. Dec. 11, 1906, Dakar, French West Africa [now in Senegal]—d. Nov. 25, 1989, Dakar), African poet and recorder of traditional folktales and legends of the Wolof people.

Diop received his education in Dakar and Saint-Louis, Senegal, and then studied veterinary medicine at the University of Toulouse until 1933. This was followed by a series of tours as government veterinary surgeon in the Sudan, Côte d'Ivoire, Upper Volta (now Burkina Faso), and Mauritania. From 1961 to 1965 he served as newly independent Senegal's ambassador to Tunisia.

He is known for his small but beautifully composed output of lyric poetry. With his compatriot Léopold Senghor, Diop helped found the Negritude (*q.v.*) movement in the 1930s, which sought a return to African cultural values. Diop explored the mystique of African life in *Leurres et lueurs* ("Lures and Glimmerings"), a selection of his verse written between 1925 and 1960.

Diop received the Grand Prix Littéraire de l'Afrique Noire in 1964 for *Les Contes d'Amadou Koumba* (1947; *Tales of Amadou Koumba*) and *Les Nouveaux Contes d'Amadou Koumba* (1958), both reprinted in the 1960s, and for *Contes et lavanes* (1963). These books contained tales that were first told him by his family's griot (a storyteller whose role is to preserve the oral traditions of his tribe). Diop's skill in rendering the nuances of dialogue and gesture furthered the popularity of his books, selections from which were reprinted in a school-text edition in 1967. *Les Contes d'Aura* ("Tales of Awa") appeared in 1978.

Diop, David (b. July 9, 1927, Bordeaux, Fr.—d. 1960, Dakar, Senegal), one of the most talented of the younger French West African poets of the 1950s, whose tragic death in an airplane crash cut short a promising career.

Diop's works in *Coups de pilon* (1956; "Pounding"), his only surviving collection, are angry poems of protest against European cultural values, enumerating the sufferings of his people first under the slave trade and then under the domination of colonial rule and calling for revolution to lead to a glorious future for Africa. That he was the most extreme of the Negritude writers (who were reacting against the assumption underlying the French policy of "assimilation" that Africa was a deprived land possessing neither culture nor history) can be seen in his rejection of the idea that any good could have come to Africa through the colonial experience and in his belief that political freedom must precede a cultural and economic revival. He wrote during the period when the struggle for independence in many African countries was at its height.

Though he himself grew up in France, his strong opposition to European society was reinforced by visits to Senegal, Guinea, and Cameroon. The Martinique poet Aimé Césaire was a dominant influence on his verse, which first appeared in the journal *Présence Africaine* and in Léopold Senghor's *Anthologie de la nouvelle poésie nègre et malgache*.

Diophantine equation, equation involving only addition, multiplication, or taking powers in which all the constants are natural numbers or their negatives and the only solutions of interest are natural numbers or their negatives. Named in honour of the 3rd-century Greek mathematician Diophantus of Alexandria (*q.v.*), these equations were not systematically solved until the 7th century by the Hindus.

Diophantus OF ALEXANDRIA (fl. AD 250), Greek mathematician, famous for his work in algebra.

What little is known of Diophantus' life is inferred from a letter of the 11th-century Byzantine scholar Michael Psellus. The only other information, which is uncertain, comes from the solution of an arithmetic epigram, which says that Diophantus married at 33 and had a son who died at age 42, four years before Diophantus' death at 84.

The *Arithmetica*, the treatise on which Diophantus' fame rests, purports to be in 13 books, but none of the surviving Greek manuscripts consists of more than 6, though one has the same text in 7. The missing books were apparently lost early, for there is no evidence that the Arabs who translated or commented on Diophantus ever had access to more than is now extant.

A fragment of Diophantus' treatment of polygonal numbers is found in *Arithmetica*. In this treatise three lemmas are mentioned that are part of his work on porisms (corollaries to theorems). These lemmas are propositions concerning number theory. One of them states that the difference of the cubes of two rational numbers is equal to the sum of the cubes of two rational numbers ($a^3 - b^3 = c^3 + d^3$). The great variety of problems presented involves first-degree determinate equations with up to four variables, determinate quadratic equations, and first-degree indeterminate equations with one or more variables. The indeterminate equations are transformed into determinate equations by assuming an arbitrary value for one of the required numbers.

Diophantus was always satisfied with a rational result and did not require a whole-number solution. Most of the work consists of problems leading to second-degree indeterminate equations, and these universally take the form that one or two (never more) linear or quadratic functions of one variable x are to be made rational square numbers by finding a suitable value for x . A few problems lead to third- and fourth-degree indeterminate equations, and one is an easy sixth-degree indeterminate equation. The problem is to find two, three, or four numbers such that different expressions involving them in the first and second degree, and sometimes the third, are squares, cubes, partly squares and partly cubes, and so forth. Book VI contains problems of finding rational right triangles such that different functions of the parts (the sides and the area) are squares.

Before Diophantus, all algebra, including the problem, operations and logic, and solution, was expressed without symbolism; he was first to introduce symbolism into Greek algebra. For an unknown quantity he used only one symbol (called *arithmos*), which characterized an undefined number of units. To avoid confusion in problems having more than one unknown term, Diophantus expressed all unknowns in terms of one of them whenever possible. The only other algebraical symbol that he used was for subtraction, also used by Hero of Alexandria (fl. 1st century AD).

The *Arithmetica* is valuable also for the propositions in the theory of numbers, other than the porisms, stated or assumed in it. Thus, Diophantus knew that no number of the form $8n + 7$ (where n is a non-negative integer) can be the sum of three squares. He also states that, if $2n + 1$ is to be the sum of two squares, " n must not be odd" (*i.e.*, no number of the form $4n + 3$, or $4n - 1$, can be the sum of two squares), and goes on to add (for the most part the condition stated by the 17th-century French mathematician Pierre de Fermat) "and the double of it increased by one, when divided by the greatest square which measures it, must not be divisible by a prime number of the form $4n - 1$." Diophantus merely omitted the condition expressed in italics.

In the light of the discovery of highly developed algebraic methods employed in ancient Babylonia, Diophantus' work no longer appears to represent a late and degenerate form of Greek mathematics. On the contrary, it was doubtless influenced by traditions common to the Hellenistic and Roman world.

BIBLIOGRAPHY. An authoritative biographical work is T.L. Heath's *Diophantus of Alexandria: A Study in the History of Greek Algebra*, 2nd ed. (1910, reprinted 1964).

diopside, common silicate mineral in the pyroxene family that occurs in metamorphosed siliceous limestones and dolomites and in skarns (contact-metamorphic rocks rich in iron); it is also found in small amounts in many chondrite meteorites. Clear specimens of good green colour are sometimes cut as gems.

Diopside is a calcium and magnesium silicate ($\text{CaMgSi}_2\text{O}_6$). It forms a complete chemical replacement series with hedenbergite in which

Diopside from De Kalb, N.Y.

Mary A. Root—EB Inc

ferrous iron completely replaces magnesium in the molecular structure. Hedenbergite is common in limestone skarns, in thermally metamorphosed iron-rich sediments, and in some igneous rocks; sodium-rich varieties are found in many alkaline rocks. Intermediate members of the series are called salite and ferrosalite; they have properties between those of diopside and hedenbergite. *See also* augite. For detailed physical properties, *see* pyroxene (table).

dioptr, in optics, unit of magnifying power of a lens or lens system. Because the power of a lens is proportional to unity (one) divided by the focal length (*see* lens), the power of a lens in diopters is numerically equal to 1 m divided by the focal length in metres. The algebraic sign of the magnifying power indicates whether the lens causes an incident pencil of parallel light rays to converge or to diverge. Thus, a diverging lens having a focal length of 1 m has a power of -1 diopter, and a converging lens of focal length 0.5 m has a power of two diopters. The power of a combination of two or more thin lenses in contact is equal to the sum of the powers of the individual lenses. For example, a lens of -10 diopters combined with a lens of 30 diopters gives a converging lens of 20 diopters (of 5 cm focal length).

Dior, Christian (b. Jan. 21, 1905, Granville, Fr.—d. Oct. 24, 1957, Montecatini, Italy), French fashion designer whose creations dominated world fashion in the decade following World War II.

Dior was born into a wealthy family and trained for the French diplomatic service, but in the midst of the financial crisis of the 1930s he went to work illustrating fashions for the weekly *Figaro Illustré*. In 1938 he became an assistant designer for the leading couturier of Paris, Robert Piguet, and four years later joined the house of designer Lucien Lelong (1889–1958).

In 1947, backed by a French textile manufacturer, Marcel Boussac, he introduced his revolutionary "New Look," spurring international controversy over the radically lowered hemline. The look featured small shoulders, a natural waistline, and a voluminous skirt, a drastic change from the World War II look of padded shoulders and short skirts.

Dior, 1957
Popperfoto

The overnight sensation of the "New Look" was followed by 10 years of outstanding success. In the 1950s the "Sack Look," or "H" line, was the characteristic silhouette of his designs. Dior was instrumental in commercializing Parisian fashion on a worldwide basis and in reestablishing the traditional superiority of Parisian over American designers.

diorama, three-dimensional exhibit, frequently housed in a cubicle and viewed through an aperture. It usually consists of a flat or curved back cloth on which a scenic painting or photograph is mounted. Flat or solid objects are placed in front of the back cloth, and coloured transparent gauze or plastic drop curtains are used to heighten the three-dimensional effect. A considerable improvement in perspective is achieved by the addition of stage borders or wings. The rigorous application of the laws of perspective is essential to the success of the exhibit. The skillful use of lighting also heightens the effect.

True dioramas, used for peep shows and the like, probably originated before the 19th century; but credit for the development of the diorama is usually given to Louis-Jacques-Mandé Daguerre, a French scenic painter, physicist, and inventor of the daguerreotype, who, with his coworker Charles-Marie Bouton, in 1822 opened an exhibition in Paris that he called the Diorama. Daguerre's techniques survive in present-day dioramas, which are widely employed, especially in museums, and may depict any subject on any scale.

The diorama is usually distinguished from the panorama, in which the background is considerably lengthened and usually viewed without restriction to an aperture, and the cyclorama, in which the background forms a complete circle around the viewer.

diorite, medium- to coarse-grained intrusive igneous rock that commonly is composed of about two-thirds plagioclase feldspar and one-third dark-coloured minerals, such as hornblende or biotite. The presence of sodium-rich feldspar, oligoclase or andesine, in contrast to calcium-rich plagioclase, labradorite or bytownite, is the main distinction between diorite and gabbro. The extrusive (volcanic) equivalent of diorite is andesite.

Diorite has about the same structural properties as granite but, perhaps because of its darker colour and more limited supply, is rarely used as an ornamental and building material. It is one of the dark gray stones that is sold commercially as black granite.

Some diorites are truly igneous; they have

crystallized from molten material (magma). Others represent the products of reaction between magma and included fragments of foreign rock. Many have been chemically transformed in the solid state from some older rock, such as gabbro, by the loss of certain constituent atoms and the gain of others. Diorite occurs in small bodies such as sills (tabular bodies inserted while molten between other rocks), dikes (tabular bodies injected in fissures), stocks (bodies intruded upward), or as more irregular masses associated with gabbro and batholiths (huge bodies) of granodiorite and granite.

Dioscoreaceae, the yam family of the flowering plant order Liliales, consisting of 6 genera with more than 500 species of herbaceous or woody vines and shrubs, distributed throughout tropical and warm temperate regions. Members of the family have thick, sometimes woody roots or tuber-like underground stems and net-veined, often heart-shaped leaves that sometimes are lobed. The small green or white flowers of most species are borne in clusters in the leaf axils. The fruit is a winged capsule or a berry. Several species of yams (vines of the genus *Dioscorea*) are grown for their edible tuberous roots, such as Chinese yam, or cinnamon vine (*D. batatas*); air potato (*D. bulbifera*); and yampee, or cush-cush (*D. trifida*).

A few species are cultivated as ornamentals. Black bryony (*Tamus communis*) is a European perennial vine with yellow flowers, poisonous red berries, and poisonous blackish root tubers. *Dioscorea* is a principal raw material used in the manufacture of birth-control pills.

Dioscorides, Pedanius (b. c. AD 40, Anazarbus, Cilicia—d. c. 90), Greek physician and pharmacologist whose work *De materia medica* was the foremost classical source of modern botanical terminology and the leading pharmacological text for 16 centuries.

Dioscorides' travels as a surgeon with the armies of the Roman emperor Nero provided him an opportunity to study the features, distribution, and medicinal properties of many plants and minerals. Excellent descriptions of nearly 600 plants, including cannabis, colchicum, water hemlock, and peppermint, are contained in *De materia medica*. Written in five books around the year 77, this work deals with approximately 1,000 simple drugs.

The medicinal and dietetic value of animal derivatives such as milk and honey is described in the second book, and a synopsis

Illustration of an aster (*Silene linoides*) in the 6th-century codex of the *De materia medica* of Pedanius Dioscorides
Graphis Magazine, Graphis Press Corp., Zurich

of such chemical drugs as mercury (with directions for its preparation from cinnabar), arsenic (referred to as auripigmentum, the yellow arsenic sulfide), lead acetate, calcium hydrate, and copper oxide is found in the fifth book. He clearly refers to sleeping potions prepared from opium and mandragora as surgical anesthetics.

Although the work may be considered little more than a drug collector's manual by modern standards, the original Greek manuscript, which was copied in at least seven other languages, describes most drugs used in medical practice until modern times and served as the primary text of pharmacology until the end of the 15th century. Authoritative editions have been published in Greek (1906-14) and in English (1934).

Dioscorus (b. Alexandria [Egypt]—d. Sept. 4, 454, Gangra, Galatia [now Cankiri, Tur.]), patriarch of Alexandria and Eastern prelate whose subscription to the unorthodox beliefs of the Monophysites caused him to be deposed and excommunicated by the Council of Chalcedon in 451. He was archdeacon at Alexandria when he succeeded St. Cyril as patriarch in 444.

He supported Eutyches, a monk of Constantinople and founder of Eutychianism (an extreme form of Monophysitism), who was condemned by a synod at Constantinople in 448. The following year Dioscorus presided over the Robber Synod of Ephesus. With the support of the Eastern Roman emperor Theodosius II, he reinstated Eutyches, excommunicated Pope Leo I the Great for censuring Eutychianism, and deposed Patriarch St. Flavian of Constantinople for opposing Monophysitism.

After Theodosius' death in 450, the Council of Chalcedon condemned all Monophysite doctrines and deposed Dioscorus, exiling him to Gangra. He was not, however, condemned as a heretic.

The Monophysite Christian churches (Coptic, Syrian, and Armenian) venerate Dioscorus as a saint.

Dioscorus (b. Alexandria [Egypt]—d. Oct. 14, 530, Rome), pope, or antipope, for 23 days in 530.

A deacon in the Alexandrian Church, he clashed with the Monophysites (Christians teaching that Christ has only one nature, rather than two—i.e., human and divine) and went to Rome. Under Pope Symmachus he was papal legate at Ravenna to the Ostrogothic king Theodoric the Great.

In 519 Dioscorus led a legation dispatched by Pope Hormisdas to Constantinople, where, with the Byzantine emperor Justinian I the Great, they concluded the Pope's resolution of the Acacian Schism, thereby reuniting the Eastern and Western churches. Hormisdas then unsuccessfully tried to have Justinian make Dioscorus patriarch of Alexandria. Later, Dioscorus headed the Byzantine party at Rome during the reign of Pope Felix IV (III). To avoid a dispute over the succession between the Gothic and Byzantine factions, Felix appointed the archdeacon Boniface (II), who was of Gothic descent, as his successor.

On Felix's death on Sept. 22, 530, a marked majority (60 out of 67) of the Roman clergy, refusing to recognize the designation of Boniface, elected Dioscorus, and both popes were consecrated simultaneously. Dioscorus' sudden death, however, ended the schism; and his partisans then supported Boniface, who in the following December convoked a Roman synod that anathematized Dioscorus. This anathema was solemnly annulled by Pope Agapetus I in 535. According to contemporary canon law, Dioscorus' claim to the papal throne was probably legitimate.

Dioscuri (from Greek *Dioskouroi*, "Sons of Zeus"), also called CASTOR AND POLLUX, or

CASTOR AND POLYDEUCES, in Greek and Roman mythology, twin deities who succored shipwrecked sailors and received sacrifices for favourable winds. They were the children of Leda and either Zeus, the king of the gods, or Tyndareus, Leda's husband. According to some versions, Castor was the son of Tyndareus and thus a mortal, while Pollux was the son of Zeus.

The twins were inseparable and became renowned for their athletic ability. A dispute between them, however, led to bloodshed; although the details are variously recorded, authorities agree that Castor, being mortal, was slain. After Pollux refused immortality in which Castor had no share, Zeus allowed them to remain together alternately in the heavens and the netherworld. Later he transformed them into the constellation Gemini.

The introduction of their cult at Rome goes back traditionally to 484 BC. The building of their temple in the Forum followed a vow of Aulus Postumius at the battle of Lake Regillus, where, according to legend, the Dioscuri fought on the side of the Romans and carried the news of victory to Rome. In art the twins are represented as two youths, usually horsemen, holding spears and wearing helmets; their image appeared on early Roman coins.

Diougou River (western Africa): *see* Cavalla River.

Dioula (people): *see* Dyula.

Diourbel, town, western Senegal, about 90 miles (145 km) east of Dakar. The market for a peanut- (groundnut-) growing area, Diourbel produces peanut oil as well as beverages and perfume. The town is the site of a beautiful mosque. Pop. (1985 est.) 76,400.

dioxin, any of a group of chemical compounds that is an undesirable by-product in the manufacture of herbicides, disinfectants, and other agents. In popular terminology, dioxin has become a synonym for one specific dioxin, 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (2,3,7,8-TCDD).

In chemical structure, a dioxin (technically called dibenzo-*p*-dioxin) consists of two benzene rings connected by a pair of oxygen atoms. Each of the eight carbon atoms on the rings that are not bonded to oxygen can bind with hydrogen atoms or atoms of other elements. By convention these positions are assigned the numbers 1 through 4 and 6 through 9. The more toxic dioxins carry chlorine atoms at these positions, and the best-known one has chlorine atoms at the 2,3,7, and 8 positions. This isomer—2,3,7,8-TCDD—is extremely stable chemically. It is virtually insoluble in water and in most organic compounds but is soluble in oils. It is this combination of properties that allows this dioxin in soil to resist dilution with rainwater and causes it to seek and enter fatty tissue in the body if it is absorbed.

Dioxin serves no useful purpose but is formed as an undesirable by-product during the synthesis of 2,4,5-trichlorophenol and some other useful compounds. The chemical 2,4,5-trichlorophenol serves as a raw material for making the herbicides Silvex and 2,4,5-T (2,4,5-trichlorophenoxyacetic acid). The latter is a major active ingredient of Agent Orange (*q.v.*), a defoliant formerly used in Vietnam by the U.S. military and in the United States to kill unwanted vegetation. This 2,4,5-trichlorophenol is also used in the production of hexachlorophene, an antibacterial agent formerly used in deodorants and soaps.

The recognition in the early 1980s that residential sites at Times Beach and elsewhere in Missouri, U.S., had been contaminated by improper disposal of chemical wastes containing 2,3,7,8-TCDD led to intense public scrutiny of its possible toxic effects. Toxicologists mistakenly concluded from studies on

laboratory animals that TCDD was one of the most toxic of all man-made substances and recommended that soil levels in excess of one part per billion might constitute a health risk to humans. It was known that TCDD could produce chloracne, a serious skin rash, but exposure to the chemical was also blamed for muscular dysfunctions, various bodily inflammations, impotency, birth defects, genetic mutations, and nervous system disorders. TCDD was also linked to various cancers.

Subsequent research, however, discounted most of these inferences, which were based on the effects of very high doses of TCDD on guinea pigs and other peculiarly susceptible animals. Among humans, the only disease definitely found related to TCDD is chloracne, which develops shortly after exposure to the chemical. Epidemiological studies on industrial workers exposed to TCDD over many years show that it has a weak carcinogenic effect at high-dose exposures and no effect whatsoever at low-dose exposures. In fact, normally occurring exposure to TCDD appears to be less of a carcinogenic risk than similar exposure to asbestos, radon, or cigarette smoke. Nor has any convincing evidence been found for the association of TCDD with other bodily disorders and defects in humans, including genetic mutations.

What toxicity TCDD does possess apparently derives from the chemical's ability to bind with a particular type of receptor protein inside some cells within the body. The resulting TCDD-receptor complex can enter the cell's nucleus and bind with its DNA, thereby disrupting the cell's machinery for producing proteins. The wide and rather puzzling array of toxic effects induced in animals by high levels of TCDD are apparently all receptor-mediated responses to that chemical. Such animals' immune systems are those most often affected, being apparently weakened or compromised by TCDD.

Dipaṅkara (Buddhist reformer): *see* Atiśa.

Dipavaṃsa (Pāli: "History of the Island"), oldest extant historical record of Sri Lanka, compiled in the 4th century. It is considered to be one of the main sources drawn upon by the author of the later and more comprehensive historical chronicle the *Mahāvamsa*. In its emphasis on ecclesiastical (Buddhist) rather than political history and in the time span of its narrative, the *Dipavaṃsa* is similar to the *Mahāvamsa*. Unlike the *Mahāvamsa*, however, the *Dipavaṃsa* is a crude, unpolished work—perhaps the first attempt of the Sinhalese people to write in Pāli, the sacred language of Buddhism. Because of its lack of organization and a heterogeneity of style, it is generally considered the product of multiple authorship.

diphenhydramine, synthetic drug used to counteract the histamine reaction, as in allergies. Introduced into medicine in 1945 and marketed under several proprietary names, including Benadryl, it is administered orally or by intramuscular or intravenous injection in the form of its hydrochloride. It has been used to control the symptoms of hay fever, acute skin reactions (such as hives), and contact dermatitis (such as from poison ivy). The most common side effect is drowsiness.

Diphenhydrochloride occurs as white crystals, soluble in water. It is available in capsules and in solution for injection.

diphenyl (chemistry): *see* biphenyl.

diphtheria, acute infectious disease caused by the bacillus *Corynebacterium diphtheriae* and characterized by a primary lesion, usually in the upper respiratory tract, and more generalized symptoms resulting from the spread of bacterial toxin throughout the body. Diphtheria was a serious contagious disease throughout much of the world until the 20th cen-

tury, when its incidence in Europe and North America was greatly reduced by immunization measures. It still occurs mainly in the temperate regions of the world, being more common during the colder months of the year and most often affecting children under the age of 10.

The diphtheria bacillus was discovered and identified in Germany by Edwin Klebs (1883) and Friedrich Löffler (1884). In most cases the bacillus is transmitted in droplets of respiratory secretions expelled by active cases or carriers during speaking or coughing. The most common portals of entry of the diphtheria bacillus are the tonsils, nose, and throat; the bacillus usually remains and propagates in that region, but the toxin that it produces is disseminated throughout the body by way of the blood and lymph vessels. This toxin, called diphtheria exotoxin, is responsible for most of the symptoms of the disease.

The symptoms of diphtheria include moderate fever, a tired feeling, chills, and a mild sore throat. The propagation of the diphtheria bacilli leads to the formation of a thick, leathery, grayish membrane that is composed of bacteria, dead cells from the mucous membranes, and fibrin (the fibrous protein associated with blood clotting). This primary lesion firmly adheres to the underlying tissues of the mouth, tonsils, pharynx, or other site of localization. The more remote lesions caused by the circulating toxin primarily affect the heart muscle and peripheral nerve tissue; in more severe cases the resulting heart failure and paralysis may lead to death.

There are several types of diphtheria, depending in large part on the anatomic location of the primary lesion. They include the following: (1) Anterior nasal diphtheria, in which the membrane appears inside the nostrils. Almost no toxin is absorbed from this site, so there is no danger to life and complications are rare. (2) Faucial, or tonsillar, diphtheria, the most common type, in which the infection is limited mostly to the tonsillar region. Most patients recover if properly treated with diphtheria antitoxin. (3) Nasopharyngeal diphtheria, the most often fatal form, in which the tonsillar infection spreads to the nose and throat structures, sometimes completely covering them with the membrane and causing toxemia (blood poisoning). (4) Laryngeal diphtheria, usually resulting from the spread of the infection downward from the nasopharynx to the larynx; the airway may become blocked, and must be restored by inserting a tube or cutting an opening in the trachea. (5) Extra-respiratory diphtheria, consisting of those forms of the infection that affect parts of the body other than the respiratory tract, notably the skin, following a wound or sore.

In response to the presence of diphtheria exotoxin, the body makes a neutralizing substance called antitoxin, which enables the affected person to recover from the disease if produced fast enough and in sufficient quantities. The only effective treatment of diphtheria is in fact the prompt administration of this antitoxin, which is obtained from the blood of horses that have been injected with exotoxin and have responded by producing antitoxin. Besides neutralizing exotoxin in the bloodstream, the antitoxin also confers a relatively long-lasting immunity on the patient.

Active protection against diphtheria has become a routine measure in many countries through immunization with diphtheria toxoid, a form of the exotoxin that has been rendered nontoxic but that has retained its capacity to induce antitoxin formation once injected into the body. The diphtheria toxoid is usually first given during the first few months of life, with booster doses within one or two years and again within five or six years of age.

diphthong, in phonetics, a gliding vowel in the articulation of which there is a continuous transition from one position to another. Diphthongs are to be contrasted in this respect with so-called pure vowels—i.e., unchanging, or steady state, vowels. Though they are single speech sounds, diphthongs are usually represented, in a phonetic transcription of speech, by means of a pair of characters indicating the initial and final configurations of the vocal tract. Many of the vowel sounds in most dialects of English are diphthongs: e.g., the vowels of “out” and “ice,” represented as [au] and [ai], respectively.

Diplodocus, genus of extinct giant sauropod dinosaurs found as fossils in Late Jurassic rocks of North America (the Late Jurassic epoch occurred 163 to 144 million years ago). *Diplodocus*, perhaps the most commonly displayed dinosaur and a relative of *Apatosaurus* (popularly *Brontosaurus*), was the longest land animal that ever lived; the longest known was 26.7 m (87.5 feet) long. The skull, unusually small, was elongate and rather light; it sat atop a very long neck. The brain was extremely small. Its relatively light body was well supported by limb girdles and pillarlike legs. While most of these dinosaurs weighed just over 10 tons, some members of the genus may have weighed as much as 80 tons. The tail was very long and probably extremely flexible. It is possible that the tail was a defensive weapon that could be lashed out at predators with great force; it is also possible that it was employed for propulsion in the water.

A mass of nervous tissue present at the base of the spine aided in the coordination of the movements of the hind limbs and tail. Because the great length of the animal would have made the transmission of nervous impulses from the tiny brain to the hindquarters a slow process, the spinal node, often mistakenly called a second brain, was developed to compensate for the time lag.

Some theories suggest that *Diplodocus* may have spent a good deal of time in the water with only its head sticking out. It is probable that *Diplodocus* could move about freely on dry land; the limbs were relatively slim and the feet broad, much like those of modern elephants. The character of the teeth—pencillike, dull-edged, and located on the anterior margins of the jaws—indicates that *Diplodocus* probably fed on soft vegetation.

Diplograptus, genus of graptolites, small, extinct colonial marine animals thought to be related to the primitive chordates and restricted to ancient marine environments. Forms or species of *Diplograptus* are useful index, or guide, fossils for the Ordovician period (which occurred from 505 to 438 million years ago) and thus allow the correlation of sometimes widely separated rock units. *Diplograptus* is characterized by a caplike float from which featherlike assemblages of graptolite organisms were suspended. It was relatively large for a graptolite; several kinds of individuals were present in a colony.

diplomacy, the established method of international discourse or art of managing international relations, chiefly by negotiation. In the past diplomacy referred to official relations between sovereign states, but in the 20th century it has expanded to cover summits and other international conferences and the activities of such entities as the United Nations, the Red Cross and Red Crescent, and the North Atlantic Treaty Organization (NATO).

A brief treatment of diplomacy follows. For full treatment, see MACROPAEDIA: Diplomacy. Diplomacy is often confused with foreign policy, but it is instead the chief instrument through which the goals, strategies, and broad

tactics—often politically determined—of foreign policy are implemented. Foreign policy is usually publicly stated; diplomacy, on the other hand, is generally conducted in secret, though its results are often made public.

Although traces exist that point to diplomacy in prehistoric societies, modern diplomacy originated in ancient Greece. Greek diplomacy first employed heralds as inviolable messengers between warring states; later, envoys chosen for their oratorical skills were sent on diplomatic missions. A special class, the proxeni, or consular agents, were distinguished from envoys by their resident missions and by the commercial tasks in which they specialized.

Roman and medieval European contributions were primarily legal: the application of civil law to treaties and the beginnings of a formal international law. In the late Middle Ages papal diplomacy played a leading role; papal legates and nuncios were the models from which secular rulers fashioned their own agents. From the 12th century these agents were called ambassadors. Italy, particularly Venice, conducted the most extensive diplomacy and influenced its development in other European states.

By the 16th century resident embassies were common throughout Europe. The presence of a number of ambassadors, each representing the dignity of his sovereign, in the various capitals led to issues of precedence among the diplomatic corps, and much diplomatic protocol descends from solutions fashioned in this period. In the 17th century the focus of diplomacy began to shift from representing the sovereign to representing the national interest; to coordinate and direct this service, in 1626 Cardinal Richelieu instituted in France the first modern foreign ministry. This trend accelerated in the 19th century as power shifted from royal courts to cabinets. Also at this time the pattern of European diplomacy began to be adopted by other nations; by the end of the century the Western diplomatic system was in evidence throughout the world.

Advances in communication and transportation in the 19th and 20th centuries changed the conduct of diplomacy. Ambassadors communicated more frequently with political leaders in the capital, and politicians themselves took an increasingly active role in diplomatic negotiations. Heads of state had attended major diplomatic conferences (such as the Congress of Vienna of 1814–15) in the past, but in the late 20th century summitry and other international conferences brought further involvement from politicians in the diplomatic process.

Diplomatic venues multiplied as well. The League of Nations and its successor, the United Nations (UN), were the most prominent international platforms, but bodies such as the European Communities, the Organization of Petroleum Exporting Countries, and the Organization of African Unity also received envoys from interested states.

As diplomacy became more public it became more hazardous. Despite extraterritoriality (*q.v.*) and other protections of diplomatic immunity, diplomats became a target of terrorists and other disaffected groups, and kidnappings and assassinations were not uncommon in the late 20th century.

The Vienna Convention on Diplomatic Relations, adopted in 1961 by the UN Conference on Diplomatic Intercourse and Immunities, recognized types of diplomatic agents and the agreed protocols from which they operate. It specified three classes of heads of missions: ambassadors or nuncios; envoys, ministers, or internuncios; and chargés d'affaires. The first two are accredited to heads of state, the third to ministers of foreign affairs. These representatives, along with members of their staffs and the consular corps, constitute a country's foreign service (*q.v.*). Their primary functions

include representing the sending state in the host state, protecting the interests of the sending state, negotiating on its behalf, gathering information on conditions and developments in the host country, and promoting friendly relations between the two countries.

Diplomatic tasks have broadened to include economic, cultural, disarmament, and other negotiations, usually conducted by or with the support of negotiators who are specialists in the field. Diplomats themselves have become more specialized in training and education, though some countries, especially small ones, continue to favour generalists in staffing their diplomatic corps.

diplomatic immunity: see extraterritoriality.

diplomatic service: see foreign service.

diplomatics, the study of documents, including documents of legal and administrative import, and public records. The major task of diplomatics is to distinguish between genuine and false documents; diplomatic studies have been applied in particular to Western documents of the Middle Ages.

A brief treatment of diplomatics follows. For full treatment, see MACROPAEDIA: History, The Study of.

Diplomatics originated during the Middle Ages in response to the large numbers of forgeries resulting from the loss of records during wartime and the new need for written substantiation of previously unwritten “customary” law. It was not until the 17th century, however, that attempts to detect forgeries began to adhere to strict, scientific methodology. Jean Mabillon, a Benedictine monk, published *De Re Diplomatic Libri VI* in 1681, in which he set out the fundamental principles of verifying documents. His work was extended by René-Prosper Tassin and Charles-François Toussaint in *Nouveau traité de diplomatique* (1750–65), and in 1821, the École des Chartes was founded in Paris for the training of archivists. In Germany and Austria, scholars furthered the science of diplomatics by differentiating between *actum* and *datum* (i.e., between verbal legal procedure and its formal documentation) and by developing a technique to authenticate the writing of individual notaries or scribes.

Today, documents are classified in various ways, including public and private, and evidentiary and dispositive. A document may be either original (drawn up on the order of the sender or donor and designated as evidence of the transaction) or a copy (made before or after the deed was actually sealed; copies made before are technically rough drafts). Certification of a copy by a notary can provide it with the same legal value as an original.

To gauge the authenticity of a document, the diplomatic scholar studies the ink used and material on which it was written, the language and abbreviations used therein, its script style, its form and content, its date, and finally the material composition of its seal.

Throughout history, documents were written on, and with, a variety of materials. Stone, metal, wax, papyrus, and parchment held the writings of antiquity; in the Middle Ages, parchment and papyrus were common, although paper was sometimes available in the 12th and 13th centuries, after which it became the material of choice. All documents were written with ink, but the colour varied from region to region.

The language used in documents throughout the Roman Empire was primarily Latin; toward the end of the 6th century AD it was superseded in the East by Greek, which remained in force in the Byzantine Empire through 1453. With few exceptions, Latin was the primary language used in Western documents until the 15th century, when the vernacular also became acceptable. In addition to the language used, the particular characteristics of the abbreviations in a document

also contribute to a correct assessment of its probable date and provenance.

Script styles provide telling evidence as to the authenticity of a document, since certain styles were dominant in some eras and disused in others. Thus, the knowledge of paleography, different styles of ancient writing, is a skill essential to diplomatics.

The form and content of documents, especially in comparison to model texts used by chanceries (letter offices of rulers and popes) provide valuable insight into their authenticity. In the case of common documents, notaries copied from books in which text formulas had been collected, adding the pertinent individual information. Official documents were normally divided into three parts: the introduction, the main text, and the concluding formula. Each of these parts contained certain standard subject matter, such as an invocation to the deity; documents which fail to adhere to standards of format and content may be of questionable validity.

The date on a document is also a clue to its validity. The date may be that of legal enactment (*actum*) or that of the issue of the document recording the (already performed) legal enactment. Dates varied depending on what calendar system was used, so the form in which the date is given is exceedingly useful in determining provenance and authenticity.

Finally, authenticity of a document can be judged by analyzing the appropriateness of the seal. Byzantine emperors, for instance, used gold seals, whereas ecclesiastics and officials of the realm used lead and silver.

Most formal documents were drawn up in chanceries throughout the Roman and Byzantine empires, in a tradition that continued through the Middle Ages and into the 17th century, at which time departmentalization obviated the need for a central letter office. Documents issued through chanceries included laws, edicts, decrees, foreign letters, administration, writs, charters, privileges, and others. For the most part, diplomatic studies have been applied mainly to Western documents, usually medieval or earlier in issue, because the validation of more recent documents requires less specialized training.

diplopia: *see* double vision.

Diplovertebron, genus of extinct amphibians of North America and Europe known from fossils in Late Carboniferous rocks (from 320

Dorsal view of *Diplovertebron* skeleton

Reprinted from *Vertebrate Paleontology* by A.S. Romer, by permission of the University of Chicago. Copyright 1933, 1945, 1966 all rights reserved

to 286 million years ago). *Diplovertebron* represents a late surviving form of the antracosours, a group of primitive amphibians that probably included the ancestors of the more advanced reptiles. *Diplovertebron* and other antracosours are characterized by a distinctively constructed vertebral column and skull pattern and five-toed feet.

dipluran, also called **APTERAN**, or **ENTOTROPHIAN**, group of small primitive wingless insects (about 400 species) of the subclass Apterygota. Some entomologists consider many of their features similar to those associated with ancestral insects. Diplurans are blind, pale insects that live in soil and feed on decaying vegetation and plant tissues; thus they often damage growing plants.

The order is divided into three families. Typ-

ically the members of the campodeid family have two long, slender abdominal cerci (sensory appendages) that are sensitive to vibra-

Dipluran (Japygidae)

William E. Ferguson

tions; these insects are commonly known as twintails. The cerci of the japygid family are modified into hard pincers that are used to catch prey. Members of the third family, the projapygids, also have cerci.

Dipnoi, order or subclass of fishes that includes living species of the lungfish (*q.v.*), as well as a number of extinct forms.

Dipo Negro, Pangeran (Prince), also called **RADEN MAS ONTOWIRJO** (b. c. 1785, Jogjakarta, Java [Indonesia]—d. Jan. 8, 1855, Makasar, Celebes), Javanese leader in the 19th-century conflict known to the West as the Java War and to Indonesians as Dipo Negro's War (1825–30). During those five years Dipo Negro's military accomplishments severely crippled the Dutch and earned for him a prominent place in the Indonesian nationalist pantheon of heroes.

The sultanate of Jogjakarta was created Feb. 13, 1755, by a Dutch treaty that dismembered the once-powerful Javanese kingdom of Mataram. Although Dipo Negro was the eldest son of the third ruler of Jogjakarta, Sultan Amangku Buwono III, he was passed over for the succession in 1814 on the death of his father in favor of a son whose mother was of higher rank, but he was promised the throne should his half brother predecease him. He was a deeply religious person who throughout that period lived in meditative seclusion, and historians disagree on whether he wanted the throne or whether he spurned it in favour of a contemplative life.

There is no doubt, however, that during the 1820s Dipo Negro came into conflict with Dutch officials and by 1825 emerged as the leader of disaffected aristocrats in the Jogjakarta region. The Java War itself was triggered by a series of draconian land reforms that undercut the economic position of the Javanese aristocrats.

There were mystical overtones to the conflict as well, drawn from traditional Javanese and from Muslim sources. Dipo Negro clearly was cast in the role of the Javanese *ratu adil* ("just prince") come to save his people, but the struggle was also seen as a Muslim *jihād* ("holy war") against the infidel Dutch. The outbreak of the war was accompanied by reports of revelations and prophecies and miraculous events.

Dipo Negro had a strong following in the Jogjakarta region and launched a guerrilla war that was quite successful for nearly three years. In late 1828, however, Dutch forces won a major victory that proved the turning point in the war. Under General H. Merkus de Kock, the Dutch proceeded to develop a system of small, mutually protecting outposts linked by good roads that enabled them to quell the natives' guerrilla warfare. In 1830 Dipo Negro agreed to meet with Dutch representatives for peace negotiations, but during the meeting he was arrested. He died in exile.

dipolar hypothesis, theory that the Earth's magnetic field is produced or is best repre-

sented by a magnetic dipole, a body having poles of opposite sign, that is, positive and negative. In the first quantitative study made of the Earth's magnetic field, William Gilbert observed that it resembled the magnetic field of a uniformly magnetized sphere. This field is the same as that of a magnetic dipole, and early theories of the origin of the geomagnetic field postulated some sort of lodestone or gigantic iron bar magnet within the Earth that gave rise to this dipolar field. Measurements and projections of pressure and temperature led to the conclusion that the Curie point (temperature at which magnetic properties are lost) of all known magnetic compounds is exceeded 10 to 40 km (6 to 25 miles) below the surface; this conclusion left the lodestone and bar-magnetic theories untenable.

Current theories postulate a self-sustaining dynamo in the Earth's core, giving rise to the magnetic dipolar field. Detailed study of the Earth's magnetic field shows the dipolar field to be the main component, although there are, in addition, irregularities caused by the superposition of a non-dipolar field, which is weaker than the dipolar field and is thought to arise in the Earth's outer core.

dipole, electric: *see* electric dipole.

dipole, magnetic: *see* magnetic dipole.

Dipolog, city, western Mindanao, Philippines. Dipolog is a fishing and interisland shipping port. There is also a commercial airport. Its city status dates from 1969; it had been a municipality since 1913 and, before that, had been considered an outer adjunct of the port of Dapitan on Dapitan Bay, some 10 miles (16 km) to the northeast. Dipolog long since outstripped the other town in size and importance, however. The city is connected with the main part of Mindanao island via the eastern Zamboanga Peninsula's scanty road system. Inc. city, 1969. Pop. (1989 est.) 78,168.

dipper, also called **WATER OUZEL**, any of four species of songbirds of the Cinclidae family (order Passeriformes) noted for insect hunting by walking underwater in rushing streams and named for their frequent body bobbing.

Eurasian dipper (*Cinclus cinclus*)

H.M. Barnfather—Bruce Coleman Inc.

Among the best-known species are the Eurasian, or white-bellied, dipper (*Cinclus cinclus*), blackish brown with a white breast, found from northern Africa and Europe to Manchuria, and the North American dipper (*C. mexicanus*), dull gray in colour, found from Alaska to Panama, east to the foothills of the Rockies. Two other species are found in mountainous areas of South America and

Asia; there is also an Asiatic species, the brown dipper (*C. pallasii*), found from the Himalayas to China, Korea, and Japan.

Dippers are plump, stub-tailed birds, about 18 cm (7 inches) long, with thrushlike bills and legs. The nest is a dome of moss built in a crevice, often behind a waterfall.

dipping duck: see dabbling duck.

Diprotodontidae, family of extinct marsupial mammals that existed from the Late Oligocene epoch into the Pleistocene epoch (from 30

Diprotodon (cast), mounted skeleton

By courtesy of the American Museum of Natural History, New York

million to roughly 10,000 years ago) in Australia. It included *Diprotodon*, which was the largest known marsupial (3.5 m [11 feet] long). *Diprotodon* was characterized by a wombatlike body the size of a large rhinoceros. Its limbs and skeleton were massively constructed to support its imposing bulk. The incisor teeth were well developed and resemble those of gnawing animals. The Diprotodontidae also included *Palorchestes*, of the Pleistocene, a large kangaroo-like marsupial. All members of the family were presumably herbivorous. They are perhaps distantly related to kangaroos and wombats.

Dipsacales, the teasel order of flowering plants, belonging to the class known as dicotyledon (*q.v.*; characterized by two seed leaves). It comprises 40 genera and about 1,100 species in four families and is distributed throughout the world, but is centred mainly in the Northern Hemisphere. The order is best known for its ornamental plants, such as the honeysuckle, the arrowwood, the wayfaring tree, the guelder rose, and the scabious.

The diversity of habitat found in Dipsacales is illustrated by the species of *Viburnum* (Caprifoliaceae family) growing naturally in eastern North America. *V. edule*, the red-fruited squashberry, inhabits moist woods from Labrador to Alaska, southward into Pennsylvania, Michigan, and Minnesota, and as far west as Colorado and Oregon. A variety of arrowwood, *V. dentatum*, thrives not only in moist woods but also in swamps. Possum haw (*V. nudum*) is largely limited to swamps of the eastern and southern coastal plain. In contrast, *V. rufidulum* (southern black haw) and *V. molle* prefer dry, rocky woods or hills.

Thirteen of the 18 genera of the honeysuckle family (Caprifoliaceae) are under cultivation. Many genera consist of relatively few species. *Viburnum*, however, has about 225 species, including the guelder rose (*V. opulus* variety *opulus*), the arrowwood (*V. dentatum*), and the Chinese snowball (*V. macrocephalum* variety *sterile*). Other significant genera of the Caprifoliaceae are *Lonicera*, *Sambucus* (elderberry), *Symphoricarpos*, and *Weigelia*.

The valerian family (*Valerianaceae*) comprises 10 genera and 400 species of herbs distributed chiefly in the Northern Hemisphere. Its members are characterized by the rank odour of their stems and leaves when dried. *Valeriana officinalis*, the garden heliotrope, is a perennial herb prized for its spicy, fragrant

flowers; it is native in Europe and western Asia. Its dried rhizome yields valerian, a natural sedative. Another member of the Valerianaceae, the spikenard (*Nardostachys jatamansi*), is a perennial herb of the Himalayas and produces an essential oil in its woody rhizomes.

The Dipsacaceae is a natural family comprising herbs placed in 8 to 12 genera and 300 species. *Dipsacus sativus* is noted for its compact head of flowers in which elongate, stiff bracts (leaflike scales) accompany each flower. The ripened heads were used even in Roman times to raise the nap of woolen cloth, a process known as fulling. (Fuller's teal has since been replaced by mechanical methods.) Another important genus of Dipsacaceae is *Scabiosa*, the pin-cushion flower genus, 21 species of which are ornamentals. Many other members of the family are cultivated as ornamentals. Himalayan whorlflower (*Morina longifolia*), sometimes placed in a family of its own, has thistlelike leaves and produces spikes of tubular flowers about 90 cm (3 feet) tall that open white and turn scarlet. *Pteroccephalus parnassi*, from mountains of southeastern Europe, is a low, perennial plant with purplish flowers. *Cephalaria transylvanica*, a tall annual, produces large, stiff, globe-shaped, white to bluish flower heads and has divided leaves. Devil's bit scabious (*Succisa pratensis*), a blue-flowered perennial, grows wild in European meadows. Its leaves are entire or slightly lobed and oval to narrow in shape.

The fourth family, Adoxaceae, consists of *Adoxa moschatellina*, the muskroot, widely distributed in northern regions. It is a low-growing, perennial herb composed of a basal cluster of leaves and a single stem. It has a musky odour (as its name implies), and its use is limited to rock gardens.

The American elderberry and the bush honeysuckle produce rhizomes that send up new shoots to propagate the species vegetatively. Such plants often form dense colonies. Seeds, however, are produced in abundance by all members of the Dipsacales growing naturally.

Inflorescences in this order range from paired flowers in the twinflower (*Linnaea*) to the showy, compactly branched, flat-topped inflorescences (cymes) produced by the American elderberry. Several other types of inflorescences are produced in certain species.

A model flower of this group of plants has four to five units in each whorl of sepals, petals, and stamens (male). Sepals may be undiverged to form a funnel-shaped calyx; petals are always fused to form an often bell-shaped corolla. Stamens are attached basally to the petals.

The pistil (female) is composed of two or more carpels in which the basal, swollen ovary is topped by a slender style that ends in the pollen-receptive stigma. Stigmas are the same in number as the chambers of the ovary, and each chamber produces one ovule. A distinctive feature of the teasel order is the departure of all floral parts from the top of the ovary; it is inferior in position.

Pollination is generally effected by insects, but in some species of honeysuckle of the western United States, hummingbirds pollinate the flowers. Following pollination and fertilization, the ovule becomes the seed and the ovary the fruit. Several types of fruits are found in the Dipsacales. Those that mature fleshy are berries, or, if the layer next to the seed is hard, drupes. Many species produce dry fruits that either split (capsules) or remain closed (achenes).

Fleshy fruits and their seeds are dispersed by birds. Some species in the teasel family produce spiny fruits or inflorescences that cling to passing animals and are scattered widely.

Features shared by most families in the Dipsacales include opposite leaves, inflorescences in cymes (oldest flowers at top), united petals, anthers separate from each other, and an in-

ferior ovary. In most genera, petals are alike in shape, but some members of the order develop two-lipped flowers in which one half of the flower is the mirror image of the other half (bilateral symmetry).

dipteran, a member of the insect order Diptera, the two-winged or "true" flies. This order contains over 85,000 species divided into three suborders: the Nematocera (midges, gnats, mosquitoes, crane flies), the Brachycera (horse flies, bee flies, robber flies), and the Cyclorrhapha (house flies, fruit flies, leafminers, blow flies). Many other insects are commonly called flies (such as dragonflies, caddisflies, and mayflies), but their wing structures serve to distinguish them from the true flies. Dipterans occur in all habitats throughout the world; one or two species of midges (*e.g.* *Pontomyia natans*) are even marine-dwelling.

A brief treatment of dipterans follows. For full treatment, see MACROPAEDIA: Insects.

The smallest dipterans are midges only 1 mm (0.04 inch) in length, and the largest are the robber flies (Asilidae), which can attain a length of nearly 8 cm (3 inches). The chief diagnostic feature of the group is wing structure. The anterior wings are functional for flight, while the posterior wings have evolved into halteres, which serve as balancing organs during flight. The earliest dipterans in the fossil record date from the beginning of the Jurassic period (about 208 million years ago).

Within the order there is great variation in the relative size of the thorax, abdomen, and legs. While some flies are bright and metallic in appearance, most are covered with a fine coating of dust (tomentum). In many species the ovipositor is a telescoping organ composed of the last few segments of the abdomen; its structure allows the fly to lay her eggs within various organic matter. Dipterans' compound eyes are large—in the house fly (*Musca domestica*) there are 4,000 facets in each eye. Antennae vary greatly in structure but are present in all species of dipterans. In flies the mouthparts have evolved for sucking. In various species of primitive flies, such as mosquitoes, the mandibles of the female are adapted to piercing the skin of vertebrates to obtain blood. Some advanced flies with this habit (tsetse flies and robber flies) have evolutionarily lost the mandibles but have evolved other structures for the purpose.

Like many other insects, flies undergo a complete metamorphosis from the egg through larva and pupa to the adult. In the more advanced flies, fewer molt stages, or larval instars, occur. In tsetse flies (*Glossina*) and three families of parasitic flies (Hippoboscidae, Nycteribiidae, and Strebelidae) only one egg is produced, and it hatches internally. The larva is nourished within the female and when mature is expelled and immediately pupates; these flies lack any free larval stage. By contrast, in many midge species the larvae lead complex, active lives, while the adult lives just long enough to mate and assure a new generation of larvae.

Most flies lay eggs. The typical number in a batch of eggs varies among species from one to 250. The site of egg deposition is chosen to place the larvae where food will be readily accessible. Fruit flies (Trypetidae, Drosophilidae) lay their eggs within rotting fruits, while blow flies (Calliphoridae) deposit their eggs in rotting meat or open wounds on living animals. Various other fly larvae, including the frit flies (Chloropidae), leafminers (Agromyzidae), and the gall midges (Cecidomyiidae), develop while feeding on plant tissues. Still other larval species are predatory. Larvae may be found in microhabitats ranging from plant and animal tissue to dung (the beetle flies, Celyphidae), underwater (the mosquitoes, Culicidae, and the black flies, Simuliidae), or in pools of petroleum seepage (the carnivorous petroleum fly [*Psilopa petrolei*]).

The larvae of primitive flies have well-developed heads, chewing mouthparts, and pseudopods or prolegs ("false legs," similar to those that support the abdomen of a caterpillar). No fly larvae have true jointed thoracic legs. In the larvae of advanced forms, known as maggots, the head is simple and the mouthparts consist only of a pair of hooks that move vertically. Two spiracles (air holes) are located at the posterior end of the maggot; prolegs are lacking.

Fly larvae frequently pupate within either a cocoon or a puparium (a case formed as the larval skin hardens). The adult emerges from the pupa soft, wrinkled, and lacking colour. It swallows air to expand the body and get its blood flowing.

Dipterans are ecologically quite important, especially in the function maggots perform in the breakdown and redistribution of organic materials. Flies are also an important link in numerous food chains. Aquatic larvae are an important food for small fish, while all the developmental stages are taken by various other vertebrates including frogs, toads, small mammals, lizards, swallows, swifts, and other species of birds.

While some flies are beneficial to man as parasites of insect pests or as scavengers, and many others are important as pollinators of various plants, flies are more familiar for their negative aspects. Many are annoying blood-sucking insects—mosquitoes (*Culicidae*), deer flies (*Chrysops*), and stable flies (*Stomoxys*), for example—while swarms of sweat flies and face flies are a nuisance as they gather to suck up sweat and other bodily secretions. In almost all species which take blood, it is done only by the female, who needs nutrients from blood in order to develop a clutch of eggs. Many dipterans are vectors of disease, and because they move from one organism to another they transmit diseases readily. House flies are known agents in the transmission of diseases such as cholera, typhoid, and dysentery. Mosquitoes transmit malaria, yellow fever, and various viral diseases. Deer flies may transmit tularemia. The tsetse flies carry trypanosomes, which cause sleeping sickness in tropical Africa. Fruit flies and frit flies can cause great damage to agricultural crops, as can gall midges and leafminers when they invade ornamental plants.

dipyre, variety of the mineral scapolite (*q.v.*).

Dirac, P(aul) A(drien) M(aurice) (b. Aug. 8, 1902, Bristol, Gloucestershire, Eng.—d. Oct. 20, 1984, Tallahassee, Fla., U.S.), English theoretical physicist who was one of the founders of quantum mechanics and quantum electrodynamics. Dirac is most famous for his 1928 relativistic quantum theory of the electron and his prediction of the existence of antiparticles. In 1933 he shared the Nobel Prize for Physics with the Austrian physicist Erwin Schrödinger.

Dirac's mother was British and his father was Swiss. Dirac grew up an introvert, spoke only when spoken to, and used words very sparingly—though with utmost precision in meaning. In later life, Dirac would become proverbial for his lack of social and emotional skills and his incapacity for small talk. He preferred solitary thought and long walks to company and had few friends. Dirac showed from early on extraordinary mathematical abilities but hardly any interest in literature and art. His physics papers and books, however, are literary masterpieces of the genre owing to their absolute perfection in form with regard to mathematical expressions as well as words.

On his father's wish for a practical profession for his sons, Dirac studied electrical engineering at the University of Bristol (1918–21). Having not found employment upon graduation, he took two more years of applied mathematics. Albert Einstein's theory of relativity had become famous after 1919 through the

mass media. Fascinated with the technical aspects of relativity, Dirac mastered it on his own. Following the advice of his mathematics professors, and with the help of a fellowship, he entered the University of Cambridge as a research student in 1923.

Dirac, 1960
Ramsey & Muspratt Ltd., Cambridge

In August 1925 Dirac received proofs of an unpublished paper by Werner Heisenberg that initiated the revolutionary transition from the Bohr atomic model to the new quantum mechanics. In a series of papers and his 1926 Ph.D. thesis, Dirac further developed Heisenberg's ideas. Dirac's accomplishment was more general in form but similar in results to matrix mechanics, another early version of quantum mechanics created about the same time in Germany. In the fall of 1926 Dirac and, independently, Pascual Jordan combined the matrix approach with the powerful methods of Schrödinger's wave mechanics and Max Born's statistical interpretation into a general scheme—transformation theory—that was the first complete mathematical formalism of quantum mechanics.

Satisfied with the interpretation that the fundamental laws governing microscopic particles are probabilistic, Dirac declared quantum mechanics complete and turned his attention to relativistic quantum theory. Often regarded as the true beginning of quantum electrodynamics is his 1927 quantum theory of radiation. In it Dirac developed methods of quantizing electromagnetic waves and invented the so-called second quantization—a way to transform the description of a single quantum particle into a formalism of the system of many such particles. In 1928 Dirac published what may be his greatest single accomplishment—the relativistic wave equation for the electron. In order to satisfy the condition of relativistic invariance, the Dirac equation required a combination of four wave functions and relatively new mathematical quantities known as spinors. As an added bonus, the equation described electron spin—a fundamental but theretofore not properly explained phenomenon.

From the beginning, Dirac was aware that his achievement also suffered from an extra set of solutions that made no physical sense, as it corresponded to negative values of energy. In 1930 Dirac suggested a change in perspective to consider unoccupied vacancies in the sea of negative-energy electrons as positively charged "holes." By suggesting that such "holes" could be identified with protons, he hoped to produce a unified theory of matter, as electrons and protons were then the only known elementary particles. Others proved, however, that a "hole" must have the same mass as the electron, whereas the proton is a thousand times heavier. This led Dirac to admit in 1931 that his theory, if true, implied the existence of "a new kind of particle, unknown to experimental physics, having the same mass and opposite charge to an electron." One year later,

this particle—the antielectron, or positron—was accidentally discovered in cosmic rays by Carl Anderson of the United States.

An apparent difficulty of the Dirac equation thus turned into an unexpected triumph and one of the main reasons for Dirac's being awarded the Nobel Prize. The power to predict unexpected natural phenomena is often the most convincing argument in favour of novel theories. Dirac drew from this experience a lesson that theoretical physicists, in their quest for new laws, should place more trust in mathematical formalism and follow its lead, even if physical understanding of the formulas temporarily lags behind. In later life, he often expressed the view that, in order to be true, a fundamental physical theory must also be mathematically beautiful. Dirac's prediction of another new particle in 1931—the magnetic monopole—seems to have demonstrated that mathematical beauty is a necessary but not sufficient condition for physical truth, as no such particle has been discovered. Numerous other elementary particles discovered after 1932 were stranger than anything the theorists could have anticipated on the basis of mathematical formulas. But for each of these new particles, an antiparticle also exists—a universal property of matter first uncovered by Dirac.

In his later work, Dirac continued making important improvements and clarifications in the logical and mathematical presentation of quantum mechanics, in particular through his influential textbook *The Principles of Quantum Mechanics* (1930). The professional terminology of modern theoretical physics owes much to Dirac, including the names and mathematical notations fermion, boson, observable, commutator, eigenfunction, delta-function, \hbar (for $h/2\pi$, where h is Planck's constant), and the bra-*ket* vector notation.

Compared with the logical clarity that Dirac accomplished in his formalization of quantum mechanics, relativistic quantum theory seemed incomplete to him. In the 1930s quantum electrodynamics encountered serious problems; in particular, infinite results appeared in various mathematical calculations. Dirac was even more concerned with the formal difficulty that relativistic invariance did not follow directly from the main equations, which treated time and space coordinates separately. Searching for remedies, Dirac in 1932–33 introduced the "many-times formulation" and the quantum analog for the principle of least action, later developed by Richard Feynman into the method of path integration. These concepts, and also Dirac's idea of vacuum polarization (1934), helped a new generation of theorists after World War II invent ways of subtracting infinities from one another in their calculations so that predictions for physically observable results in quantum electrodynamics would always be finite quantities. Although very effective in practical calculations, these "renormalization" techniques remained, in Dirac's view, clever tricks rather than a principled solution. He hoped for a revolutionary change in basic principles that would bring the theory to a logical consistency comparable to what had been achieved in non-relativistic quantum mechanics. Although Dirac probably contributed more to quantum electrodynamics than any other physicist, he died dissatisfied with his own brainchild.

Dirac taught at Cambridge after receiving his doctorate there, and in 1932 he was appointed Lucasian Professor of Mathematics, the chair once held by Isaac Newton. In 1937 he married Margit Balasz (née Wigner; sister of Hungarian physicist Eugene Wigner). Dirac retired from Cambridge in 1969 and, after various visiting appointments, held a professorship at Florida State University, Tallahassee, from 1971 until his death.

Dire Dawa, town, east-central Ethiopia, located on the eastern edge of the East African Rift Valley, 30 miles (48 km) northwest of Harer. It lies at the intersection of roads from Addis Ababa, Harer, and Djibouti and has an airport. Dire Dawa, for long a caravan centre, developed as the chief outlet for Harer trade after 1904, when it became the terminus of the railroad from the port of Djibouti (since ex-

Mosque in the old quarter of Dire Dawa, Eth.
Victor Englebert—De Wys Inc

tended to Addis Ababa). The Dachatu River, whose bed can be crossed on foot during the dry season, divides the town into modern and old quarters. The former, built by the French, contains a Coptic church and a royal palace. Within the old quarter are a mosque and a large Muslim cemetery. Grain is imported from the highlands to the south because the dry fields around Dire Dawa (which means "empty plain") yield little to cultivation. The town has railway workshops, textile and cement factories, and coffee- and meat-canning plants and trades in coffee and hides. Most of its inhabitants are Oromo (Galla) or Somali people. Nearby are caves decorated with prehistoric paintings. Pop. (1987 est.) 107,287.

dire wolf (species *Canis dirus*), wolf that existed during the Pleistocene Epoch (1,600,000 to 10,000 years ago). It is probably the most common mammalian species to be found preserved in the La Brea Tar Pits in southern California. The dire wolf differed from the modern wolf in several ways: it was larger and it had a more massive skull, a smaller brain, and relatively light limbs. It is probable that *Canis dirus* was less intelligent than are modern wolves. The species was considerably widespread, and skeletal remains have been

Dire wolf (*Canis dirus*) from Rancho La Brea, California, detail of a mural by Charles R. Knight, 1922

found in Florida, the Mississippi Valley, and the Valley of Mexico.

Direct Action, French ACTION DIRECTE, French clandestine terrorist group that emerged in 1979 and is believed to have been an amalgam of earlier extremist groups. Sometimes compared with older terrorist groups such as the Italian Red Brigades and the German Red Army Faction, Direct Action is said to subscribe to an ideology described variously as communist, anarchist, or Maoist, with strong sympathies for Third World aspirations. Among its founders are thought to be Jean-Marc Rouillan, Nathalie Menigon, Régis Schleicher, and André Oliver. These four were among 20 Direct Action members arrested in 1986–87. Eighteen members of the group were convicted in 1988 on charges of criminal conspiracy.

Under official ban by the French government since 1982, Direct Action made bomb or gunfire attacks on various "capitalist" targets, such as employers' association offices and factories, and various public targets, such as police stations, magistrate courts, and military sites. In addition to carrying out more than 80 terrorist bombings, the group assassinated such public figures as Georges Besse, chairman of the Renault automobile company (1986), and René Audran, an official of the French Defense Ministry (1985). It engaged in a number of anti-Jewish raids, including a machine-gun and grenade attack against a Jewish restaurant.

direct current, abbreviation DC, flow of electric charge that does not change direction. Direct current is produced by batteries, fuel cells, rectifiers, and generators with commutators. Direct current was supplanted by alternating current (AC) for common commercial power in the late 1880s because it was then uneconomical to transform it to the high voltages needed for long-distance transmission. Techniques that were developed in the 1960s overcame this obstacle, and direct current is now transmitted over very long distances, even though it must ordinarily be converted to alternating current for final distribution. For some uses, such as electroplating, direct current is essential. *See also* electric current.

direct dye, also called SUBSTANTIVE DYE, any of a class of coloured, water-soluble compounds that have an affinity for fibre and are taken up directly, such as the benzidine derivatives. Direct dyes are usually cheap and easily applied, and they can yield bright colours. Washfastness is poor but may be improved by aftertreatment. Most packaged dyes sold for home use are direct dyes. *See also* mordant dye.

direct-mail marketing; *see* mail-order business.

directing, the art of coordinating and controlling all the elements in the staging of a play, opera, motion picture, television program, or radio script. The responsibility for this control is usually delegated to one person, called the director.

A brief treatment of directing follows. For full treatment, *see* MACROPAEDIA: Theatre, The Art of the; Motion Pictures.

The director did not become a dominant force in the theatre until the mid-19th century. Before then it was not uncommon for an experienced actor to advise the other members of a troupe. But with the rise of modern realistic drama came the need for someone to coordinate all the elements of a production from a perspective broader than that of a member of the cast.

Madame Vestris in England and George II, duke of Saxe-Meiningen, in Germany directed plays in which they did not act, abandoning artificial, stagy costumes and demanding authentic sets and speech. On a tour of Russia

in 1890, Meiningen caught the attention of Konstantin Stanislavsky, whose reforms of the crafts of directing and acting were influential long after his death in 1938. His name is inextricably linked to the psychological dramas of Anton Chekhov and to the actor's training technique known as the Stanislavsky method.

The theatrical elements available to the director are the script and the acting of the players, as well as the decor, costuming, lighting, visual and sound effects, incidental music, and—in a musical play—choreography. Using all these elements, the director shapes the overall production in order to leave the audience with an imaginative interpretation of what the playwright has written.

Since the actors usually constitute the most important and the most variable theatrical element, an understanding of acting and of human nature are indispensable in a director. In most cases, the director does not tell the actors every detail of what he expects of them, nor does he control their actual performance. Rather, he stimulates their imaginations and gives them confidence in their own creativity, with the idea that they will begin by knowing less than he does about their roles and end by knowing more. Casting—choosing the actor to fit the role—often is the sole responsibility of the director, since a single miscast role can ruin an entire production.

In the rehearsal the director's skills as manager as well as craftsman become important. The actors must be integrated into the set and their physical movements "blocked," or arranged. The director must compose a "stage picture" that gives the desired emphasis to the spoken word. He must also oversee the designers, stage technicians, and sometimes the choreographer and orchestra conductor. The direction of these disparate—and often competing—elements requires a broad and unifying vision that subordinates the parts of the production to the play as a whole.

Modern film directors oversee the same elements that theatre directors do, as well as such technical factors as cinematography, editing, and sound recording. The first motion-picture directors did not realize the artistic control that these technical elements allowed; they simply filmed short vaudeville or circus acts and brief action-filled views of real life from start to finish without moving the camera. Soon, however, film directors learned to use camera placement and movement to focus viewer attention on a particular area or person, and they discovered that they could use editing to create narrative or dramatic effects. Later developments in motion-picture technology, such as the introduction of sound and colour, inspired further innovations in film-directing technique.

Two techniques that are sometimes used to describe motion-picture directing styles are montage and mise-en-scène. Montage directors are primarily concerned with editing and the relationships of individual shots to one another. D.W. Griffith was one of the first directors to use montage expressively, as in *The Birth of a Nation* (1915). Theories of montage were further developed by Soviet filmmakers of the 1920s, especially Sergey Eisenstein and Vsevolod Pudovkin. Mise-en-scène directors concentrate on the relationships between the elements within a shot and on the processes that precede the editing stage, such as camera movement, pictorial composition, lighting, and design. Directors known for their use of mise-en-scène include Orson Welles, Max Ophuls, Jean Renoir, and Mizoguchi Kenji. In most traditional Hollywood feature films, which are characterized by their fast pace and "invisible" editing style, both montage and mise-en-scène techniques are used, but montage usually dominates.

Directing television programs for live broadcast presents a situation similar to that of working on the stage. The performance is

continuous and cannot be stopped to correct mistakes. The director must edit from the control room as the program is being broadcast, making split-second decisions about when to cut from one camera shot to another.

Television directors working on programs for future broadcast have the same basic functions as motion-picture directors, although they usually have less artistic control.

The radio director's responsibilities, like those of the television director, differ for live and recorded material. In general, however, the director of a radio play needs an acutely sensitive ear to ensure that the actors' inflections and vocal rhythms produce expressive speech and that the total play with all its music and sound effects can be visualized clearly in a listener's mind.

direction field, way of graphically representing the solutions of a first-order differential equation without actually solving the equation. The equation $y' = f(x, y)$ gives a direction, y' , associated with each point (x, y) in the plane that must be satisfied by any solution curve passing through that point. The direction field is defined as the collection of small line segments passing through various

Direction field

points having a slope that will satisfy the given differential equation (see Graph) at that point. The actual family of curves (solutions of the differential equation) must have a direction at each point that agrees with that of the line segment of the direction field at that point, so that this method is valuable for gaining some feeling for the behaviour of the solutions in cases in which the equation is difficult to solve or in which the solution is a complicated function. Often it is helpful when drawing the direction field to determine the lines or curves, called isoclines, on which the slope of the direction field segments is constant. For example, in the equation $y' = x + y$ the slope will have the constant value k when $k = x + y$, or when $y = -x + k$; that is, the isoclines are straight lines with a slope of -1 . These lines can then be sketched in lightly to aid in constructing the direction field (see Graph). The actual family of solutions in this case is $y = ae^{-x} - x - 1$ for any constant a , as found by methods of differential equations.

direction finder, radio receiver and antenna system for determining the direction of the source of a signal. A direction finder may be a ground station that takes bearings on ships or aircraft, a device used for military or investigative purposes, or an airborne or shipborne navigational device, also called a radio compass.

The directional property of a radio antenna that is formed into a coil or loop was familiar to the earliest experimenters. As a loop is rotated horizontally its energy output, derived from the interception of a radio wave, passes through a sharp minimum that corresponds to the direction of the radio transmitter. Soon after ships were first equipped with radio, shore direction-finding (DF) stations were placed at strategic points along navigational routes and near harbour approaches. Upon receiving a request by radio from a ship, two or more shore

stations determined the directions from which the ship's signal arrived by means of their loop antennas and transmitted this information back to the vessel. However, this service was limited to one vessel at a time, a serious drawback in bad weather, when demands were heavy. By reversing the process—placing the transmitter ashore and the direction finder on the ship—the system became nonsaturable and the navigator was given two further advantages: he was able to take continuous or frequent bearings on any shore beacon, and he could take bearings of any receivable signal, such as transmissions from broadcasting stations and from other vessels. This change in the system was roughly coincident with the initial growth of aviation, and the airborne direction finder immediately became a valuable aid to air navigation.

Crossed-loop direction finders, used when it is not convenient to rotate the loop, consist of two loops mounted at right angles to each other with their terminals connected by cable to two crossed fixed coils of a goniometer; a rotatable coil in the goniometer simulates the rotation of the ordinary loop antenna. Other types of DF antennas include the Adcock (using spaced dipoles or monopoles) and spaced-loop types that have been employed ashore as navigational aids in the high-frequency and very-high-frequency bands, where greater efficiency and accuracy is obtained than with the simple loop. Loops incorporating ferromagnetic cores are largely used in portable direction finders, produced principally for aircraft and small boats.

Directoire style, style of dress, furniture, and ornament popular in France during the period of the Directory (1795–99). Dress for men, mixing ancient and contemporary elements, featured trousers and high boots, vests, long, open coats, and top hats. Women dressed in chemises that had long sleeves and V necklines, and they wore ruffled caps gathered around the ears, as in Jacques Louis David's portraits of Madame and Monsieur de Sériziat (1795; Louvre, Paris).

Model of a Directoire bathroom and boudoir in the Pompeiian style adapted from designs by the architect François-Joseph Bélanger (1745–1818); in the Art Institute of Chicago

By courtesy of Thorne Rooms in Miniature, the Art Institute of Chicago

Furniture and ornaments stressed elongated, simple shapes with clear lines; the Directoire style's sparse detail and ornamentation were based mostly on ancient Roman objects recently recovered from excavations at Pompeii. Directoire furniture was the last phase of the Louis XVI style.

Directory, French DIRECTOIRE, the French Revolutionary government set up by the Constitution of the Year III, which lasted four years, from November 1795 to November 1799. It included a bicameral legislature known as the Corps Législatif. The lower house, or Council of Five Hundred (Conseil

de Cinq-Cents), consisted of 500 delegates, 30 years of age or over, who proposed legislation; the Council of Ancients (Conseil des Anciens), consisted of 250 delegates, 40 years of age or over, who held the power to accept or veto the proposed legislation. The Ancients also picked the executive—the five Directors (Directeurs)—from lists drawn up by the Five Hundred. A Director had to be at least 40 years old and to have formerly served as a deputy or minister; a new one was chosen each year, on rotation. The Directors chose governmental ministers, ambassadors, army generals, tax collectors, and other officials. However, though nominally inheriting many of the centralized powers of the former Committee of Public Safety (see Public Safety, Committee of), they had no funds to finance their projects or courts to enforce their will. The Directory was a fatal experiment in weak executive powers; it was created in reaction to the puritanical dictatorship that had existed under the Reign of Terror of 1793–94, and it would end up yielding to the more disciplined dictatorship of Napoleon Bonaparte.

The Directory was perhaps the most corrupt regime that France has ever known. Its policies were aimed, first, at protecting and increasing the profits of those in political and economic power and, second, at preventing the return of the Bourbons or the establishment of any other regime that might endanger those in power by such means as the redistribution of national property. The period was also noted for extravagant fashions in dress, excesses in entertainment, and a loose morality.

Diriamba, city, southwestern Nicaragua. It lies in the Diriamba Highlands at an elevation of 1,891 feet (576 m). Diriamba is a major commercial and manufacturing centre; its hinterland is known primarily for its coffee, but lumbering is also significant. Limestone quarries and saltworks are located in the vicinity, and the city contains several processing

plants. It lies on the Pan-American Highway south of Managua and just west of Jinotepe. A branch of the Pacific Railway terminates in Diriamba. It was a scene of heavy fighting between Sandinista guerrillas and government troops in 1978–79, with serious damage to property. Pop. (1985 est.) 19,728.

Dirichlet, Peter Gustav Lejeune (b. Feb. 13, 1805, Düren, French Empire [now in Germany]—d. May 5, 1859, Göttingen, Hanover), German mathematician who made valuable contributions to number theory, analysis, and mechanics. He taught at the universities of Breslau (1827) and

Berlin (1828–55) and in 1855 succeeded Carl Friedrich Gauss at the University of Göttingen.

Dirichlet made notable contributions still associated with his name in many fields of mathematics. In number theory he proved the

Dirichlet

By courtesy of the University Library Göttingen, W Ger.

existence of an infinite number of primes in any arithmetic series $a + b$, $2a + b$, $3a + b$, \dots , $na + b$, in which a and b are not divisible by one another. He developed the general theory of units in algebraic number theory. His *Vorlesungen über Zahlentheorie* (1863; "Lectures Concerning Number Theory"), with later addenda, contains some material important to the theory of ideals.

In 1837 Dirichlet proposed the modern concept of a function $y = f(x)$ in which for every x , there is associated with it a unique y . In mechanics he investigated the equilibrium of systems and potential theory, which led him to the Dirichlet problem concerning harmonic functions with prescribed boundary values. His *Gesammelte Werke* (1889, 1897; "Collected Works") was published in two volumes.

Dirichlet problem, in mathematics, the problem of formulating and solving certain partial differential equations that arise in studies of the flow of heat, electricity, and fluids. Initially, the problem was that of determining the equilibrium temperature distribution on a disk from measurements taken along the boundary. The temperature at points inside the disk must satisfy a partial differential equation called the Laplace equation corresponding to the physical condition that the total heat energy contained in the disk shall be a minimum. A slight variation of this problem occurs when there are points inside the disk at which heat is added (sources) or removed (sinks) as long as the temperature still remains constant at each point (stationary flow), in which case Poisson's equation is satisfied. The Dirichlet problem can also be solved for any simply connected region—i.e., containing no holes—if the temperature varies gradually along the boundary.

In the related Neumann problem, heat is supplied and removed across the boundary in such a way as to maintain a stationary temperature distribution. In Robin's problem, heat is merely allowed to be lost through radiation across the boundary at a rate proportional to the temperature drop across it, resulting in the eventual stabilization of the temperature distribution. Aside from heat flow, there are other phenomena that result in similar mathematical formulations, as in electrical charge distribution and steady fluid flow. These are special cases of the more general boundary-value problems of the class of second-order partial differential equations called elliptic equations.

Dirichlet's theorem, statement that there are an infinite number of prime numbers (those not divisible by an integer larger than one except themselves) contained in the collection of all numbers of the form $(a \times n) + b$, in which the constants a and b are natural numbers or

their negatives, that have no common divisors except the number 1 and themselves, and the variable n is any natural number. Conjectured by the 18th–19th-century German mathematician Carl Friedrich Gauss, the statement was first proved in 1826 by the French mathematician Peter Gustav Lejeune Dirichlet.

dirigible: see airship.

Dir'iyah, Battle of ad- (1818), major defeat dealt the Wahhābīs, fanatical and puritanical Muslim reformers of Najd, central Arabia, by the forces of the Egyptian ruler Muḥammad 'Alī Pasha; the Wahhābī empire was destroyed, and the Sa'ūdī family that created it was virtually wiped out.

Wahhābī attacks on pilgrim caravans crossing Arabia concerned the Ottoman Turkish government at the end of the 18th century (the Ottoman sultan was protector of Mecca, Islām's chief holy city). When the Ottomans attempted to invade al-Ḥasā', eastern Arabia, the Wahhābīs responded by seizing the holy city of Karbalā' in Turkish Iraq (1801), then capturing Mecca itself (1802). Preoccupied in other directions, the Sultan did not send another force into Arabia until 1811, when he assigned to Muḥammad 'Alī Pasha, the virtually independent viceroy of Egypt, the task of crushing the "heretics." For the next four years, the balance of power shifted back and forth between Muḥammad 'Alī and Sa'ūd.

In 1815 Sa'ūd's successor, 'Abd Allāh I, sued for peace, and the Egyptians withdrew from Najd. The following year, however, Ibrāhīm Pasha, one of the Viceroy's sons, took command of the Egyptian forces. Gaining the support of the volatile Arabian tribes by skillful diplomacy and lavish gifts, he advanced into central Arabia to occupy the towns of 'Unayzah, Buraydah, and Shaqrā'. Joined now by most of the principal tribes—Harb, 'Unayzah, Muṭayr, Banū Khālid—he appeared before the Wahhābī capital ad-Dir'iyah in April 1818. After six months of intermittent and desperate fighting, 'Abd Allāh surrendered (Sept. 9, 1818) and was sent to Constantinople, where he was beheaded. Ad-Dir'iyah was razed to the ground, and Egyptian garrisons were posted to the principal towns. Several members of the Sa'ūdī family managed to escape before the surrender; the rest were sent to Egypt to prison.

Consult the INDEX first

Dirk Hartog Island, Australian island in the Indian Ocean, just north of Edsel Land Peninsula, Western Australia. Naturalist Channel passes north to enter Denham Sound (which washes the eastern shore), and Shark Bay lies to the northeast. The island was named after a Dutch navigator who arrived in 1616 and nailed an inscribed pewter plate to a post at its northern extremity (Cape Inscription), which is now the site of a lighthouse. The island, the state's largest, measures 48 mi (77 km) by 3–7 mi (5–11 km), has an area of 239 sq mi (620 sq km), and supports a sheep station. From overhanging limestone cliffs, which rise above 600 ft (180 m) along its seaward (western) edge, it descends to sand dunes along the east. The island's West Point marks Australia's westernmost point.

Dirks, Rudolph (b. Feb. 26, 1877, Heide, Ger.—d. April 20, 1968, New York City), U.S. cartoonist who created the comic strip "Katzenjammer Kids."

At the age of 7 Dirks moved with his family to Chicago, and at 17 he went to New York City, where he worked as staff artist for William Randolph Hearst's *New York Journal*. There, inspired by Wilhelm Busch's *Max und Moritz*, a picture story that Hearst had seen in Germany, Dirks, in 1897, created the "Katzenjammer Kids." When he joined the

New York World in 1912, he lost his right to the name "Katzenjammer Kids," and so he renamed the strip for the mischievous Katzenjammer brothers, Hans and Fritz, later retitling it "The Captain and the Kids" because of World War I anti-German sentiment. The "Katzenjammer Kids" continued, but as the work of another artist, H.H. Knerr. Toward the end of his life, Dirks, who was a self-taught artist, devoted most of his time to marine and landscape painting, leaving the work of the strip to his son John, who continued it after his father's death.

Dirksen, Everett McKinley (b. Jan. 4, 1896, Pekin, Ill., U.S.—d. Sept. 7, 1969, Washington, D.C.), U.S. politician, leader of the Senate Republicans during the Kennedy and Johnson administrations.

Dirksen attended the University of Minnesota, left before graduating to serve in World War I, and, after his discharge, returned to Pekin, where he pursued a number of business interests. In 1926, with his election to the office of city finance commissioner in Pekin, Dirksen began what was to become a lifelong career in public service. Defeated in 1930 in his bid for a congressional seat, he ran again in 1932 and won. A conservative Republican, Dirksen voted against most New Deal measures—except Social Security. He also opposed Roosevelt's foreign policy, adhering to an isolationist stance. In a foreshadowing of his later moderation and flexibility, however, Dirksen switched to bipartisan support of presidential foreign policy with U.S. entry into World War II.

A severe eye ailment forced Dirksen to resign his House seat in 1948. He returned to Pekin to practice law, having completed his legal education and gained admittance to the bar while in Congress. By 1950 his health was fully restored, and he ran successfully for a seat in the Senate. Throughout the 1950s, Dirksen belonged to the so-called old guard conservative wing of the Republican Party. He backed Sen. Robert A. Taft for the 1952 presidential nomination, and he supported the anti-Communist crusade of Joseph A. McCarthy until the Wisconsin senator was discredited in the middle of the decade.

Elected minority leader of the Senate in 1959, Dirksen continued to voice support for several conservative policies, including the permitting of prayer in public schools. But he played a crucial role in securing passage of major pieces of liberal legislation in the 1960s: the Nuclear Test Ban Treaty, the Civil Rights Act of 1964, and the Voting Rights Act of 1965.

In his constituency, in the Senate, and through the medium of television, Dirksen became something of a folk hero for his rich bass voice and imposing oratorical style, attributes for which his critics dubbed him "the wizard of ooze." He won his last election in 1968 and served in the Senate until his death the following year.

dirty sandstone: see graywacke.

Dis Pater (Latin: Rich Father), in Roman religion, god of the infernal regions, the equivalent of the Greek Hades (*q.v.*), or Pluto (Rich One). Also known to the Romans as Orcus, he was believed to be the brother of Jupiter and was greatly feared. His wife, Proserpina (a Roman corruption of the Greek Persephone [*q.v.*]), was identified with vegetation, being regarded as a goddess of death during her annual sojourn in the underworld and of abundance during her term in the upper regions.

Disa, genus of orchids, family Orchidaceae, containing as many as 200 species of plants. They grow in marshes and grasslands in southeastern Africa, Madagascar, and on nearby islands.

Most species bear flowers ranging in colour from white to purple and in diameter from about 0.5 to 10 centimetres (about 0.2 to 4

inches). The upper sepal of each flower usually has a spur and stands upright, forming a hood. Red disa (*Disa uniflora*), a South African species, bears pink and scarlet flowers.

disaccharide, also called **DOUBLE SUGAR**, any substance that is composed of two molecules of simple sugars (monosaccharides) linked to each other. Sucrose, which is formed following photosynthesis in green plants, consists of one molecule of glucose and one of fructose; lactose (milk sugar), found in the milk of all mammals, consists of glucose and galactose; and maltose, a product of the breakdown of starches during digestion, consists of two molecules of glucose. Another important disaccharide, trehalose, which is found in the circulating fluid of many insects, also consists of two molecules of glucose, but they are linked in a way such that trehalose differs from maltose.

disarmament, in international relations, any of four distinct conceptions: (1) the penal destruction or reduction of the armament of a country defeated in war (the provision under the Versailles Treaty [1919] for the disarmament of Germany and its allies is an example of this conception of disarmament); (2) bilateral disarmament agreements applying to specific geographic areas (naval disarmament in this sense is represented by the Rush-Bagot Agreement between the United States and Great Britain, which, since 1817, has kept the Great Lakes disarmed); (3) the complete abolition of all armaments, as advocated by utopian thinkers and occasionally by governments; and (4) the reduction and limitation of national armament by general international agreement through such international forums as the League of Nations, in the past, and the United Nations, in the present. This last is the most frequent current use of the term.

Disarmament has become a more urgent and complicated issue with the rapid development of nuclear weapons capable of mass destruction. Since the explosion of the first atomic bombs in 1945, the previous contention that armaments races were economically inexpedient and led inevitably to war was replaced by the argument that the future use of nuclear weapons in quantity threatened the continued existence of civilization itself. During the post-World War II period, there were discussions at several levels with a view to the limitation and control of armaments. Efforts ranged from continuous talks at the United Nations to such discussions among nuclear powers as the Strategic Arms Limitation Talks (SALT) of the 1970s and the Strategic Arms Reduction Talks (START) of the 1980s. *See also* arms control.

disbarment, the process whereby an attorney is deprived of his license or privileges for failure to carry out his practice in accordance with established standards. Temporary suspension may be employed if some lesser punishment is warranted.

Grounds for disbarment vary considerably from country to country, but, in general, conviction of an attorney for a major crime or a felony or his inability to account for a client's funds entrusted to him constitute the major reasons.

The procedures for disbarment also vary from country to country. In some countries the bar association upon receipt of a complaint will hold a hearing. If the committee decides that the evidence is sufficient for disbarment or other punishment, it will make such a recommendation to the appropriate court. This court will then hear the evidence and the committee's recommendations and make its decision. In some countries—Israel, for example—the bar organizations are themselves empowered to deal with these matters in their totality. In England the Inns of Court (the governing body of barristers) and the Law

Society (the governing body of solicitors) both have the power to remove the attorneys within their respective organizations from the rolls.

Disbrowe, John (English soldier): *see* Desborough, John.

disc jockey, also spelled **DISK JOCKEY**, person who conducts a program of recorded music on radio, on television, or at discotheques or other dance halls. Disc jockey programs became the economic base of many radio stations in the United States after World War II. The format generally involves one person, the disc jockey, introducing and playing phonograph records and chatting informally and usually extemporaneously in the intervals.

The idea of the program originated in the 1930s, but its development was hampered by a Federal Communications Commission rule that required stations to identify recorded music frequently—so frequently, as it turned out, that the message tended to irritate and alienate the listener. The disc jockey was also restricted by musicians and artists whose phonograph labels bore the warning "Not Licensed for Radio Broadcast." But the show's potential was revealed when Martin Block broadcast his *Make Believe Ballroom* on station WNEW in New York City as filler between news coverage of the closely followed trial of the kidnapper of the Charles A. Lindbergh baby. Upon the request of thousands of listeners, the makeshift show was retained by the station after the kidnap trial. In 1940 the Federal Communications Commission relaxed its rules, requiring that recorded material be identified only twice in an hour, and in the same year the courts ruled that the warning on record labels had no legal significance. From that time disc jockey shows became increasingly popular.

The radio disc jockey's future was clouded again during World War II by industry wage disputes with the American Society of Composers, Authors, and Publishers (ASCAP) and the American Federation of Musicians. At issue was the declining demand for live appearances of artists because of the popularity of disc jockeys and recorded music. In 1944 the disputes were settled, and wartime controls on vinylite and shellac, the materials from which phonograph records were made, were eased.

By the 1950s listener loyalty to disc jockeys was so firmly established that the success of any record depended on the preferences of the disc jockey. To solicit their favour, record companies began to shower the disc jockeys with money, stocks, or gifts (commonly known as payola). This widespread practice of commercial bribery was given national exposure by a federal investigation in 1959. As a result, payola faded for a while, but in the mid-1980s new exposés revealed that the practice continued to exist in many quarters.

The disc jockey format was never as popular on television as on radio, with the exception of a few dance shows.

discharge printing, also called **EXTRACT PRINTING**, method of applying a design to dyed fabric by printing a colour-destroying agent, such as chlorine or hydrosulfite, to bleach out a white or light pattern on the darker coloured ground. In colour-discharge printing, a dye impervious to the bleaching agent is combined with it, producing a coloured design instead of white on the dyed ground. *See also* resist printing; roller printing.

Disciples of Christ, group of Protestant churches that originated in the religious revival movements of the American frontier in the early 19th century. The three major bodies are the Churches of Christ, the Christian Church (Disciples of Christ), and the Udenominational Fellowship of Christian Churches and Churches of Christ. Related churches exist outside the United States. All have attempted to restore what they have interpreted to be

the "ancient order" of the church and have repudiated "human creeds."

A brief treatment of the Disciples of Christ churches follows. For full treatment, *see* **MACROPAEDIA: Protestantism: Disciples of Christ**.

The Great Western Revival (1801) produced a variety of religious movements dedicated to overcoming the barriers of denominationalism through a return to primitive Christianity. Two of these movements, located on the trans-Appalachian frontier and associated with the names of Thomas and Alexander Campbell and Barton W. Stone, merged in 1832 to become the Disciples of Christ. The new denomination grew rapidly with the frontier.

Despite the merger, the essential program of the Disciples—the unity of all Christians on the basis of New Testament faith and practice—failed to unite a divided Protestantism, and, in fact, proved to be divisive even within the movement as it struggled to define more precisely that common platform. (It must be noted that these controversies were reinforced by a series of historic, geographic, and cultural factors.) For the segment of Disciples that was to become the Churches of Christ, that platform meant that every aspect of faith, organization, and worship had to conform to New Testament prescription or precedent. Hence when societies for missions and for the publication of tracts appeared around 1849, and when churches began using reed organs to accompany congregational singing during worship, charges of unscriptural innovation were raised. A division over these issues emerged during and after the American Civil War and was formally ratified by a request from the conservatives for a separate listing in the 1906 U.S. census (*see* Christ, Church of).

Following a very different path, the Christian Church (Disciples of Christ) gradually abandoned its primitivist platform and advocated instead a program of unity based on an already existing and generally recognized common faith in Christ. This branch of Disciples is the most widely known of the three, in part because it has identifiable denominational structures including a general office and a biennial delegate assembly. It participates in the National Council of Churches and the World Council of Churches and generally supports the positions of these organizations in social and theological matters.

While some congregations have experimented with liturgical forms, typical Christian Church worship still generally retains the basic elements of prayer, singing, preaching, and a weekly memorial observance of the Lord's Supper. Congregations have a high level of autonomy but acknowledge regional and general structures as equal "manifestations" of the church. In recent years the quest for Christian unity has been pursued through participation in the Consultation on Church Union since its formation, and in 1985 the Disciples of Christ entered into an ecumenical partnership with the United Church of Christ.

A number of congregations tracing their roots to the Disciples movement neither claim affiliation with the Christian Church (Disciples of Christ) denomination nor reject the use of musical instruments in worship. Most of these congregations continue to hold to a "Restoration" program. They began to separate from the Christian Church (Disciples of Christ) during and after World War I over such issues as ecumenical cooperation in missions, biblical criticism, and the rising influence of liberal theology. As early as the 1920s alternative strategies for overseas missions were developed, Bible colleges were established to prepare a ministry true to the Restoration tradition, and in 1927 a separate annual gathering, the North American Christian Convention, was

called. The division was formalized in the late 1960s when the Christian Church (Disciples of Christ) underwent restructuring, and many conservative congregations still in some cooperation with that more liberal body formally withdrew. As a group they continue to reject denominational status, retaining their group identity as a "movement" mainly through periodicals, annual conventions, and Bible colleges and seminaries.

The World Convention of Churches of Christ remains the only institutional manifestation of the common Disciples of Christ heritage. Organized in 1930, it meets every five years for worship and fellowship. Some member groups originated independently of American Disciples but associate in the convention because of similarities of doctrine and practice.

Discipline, Manual of (Essene document): see Manual of Discipline.

Disco Island, *Disco* also spelled *DISKO* (Greenland): see Qeqertarsuaq.

Discoglossidae, family of primitive toads (order Anura) whose tongues are disk-shaped. The family contains four genera, which are confined to the Old World. Representatives occur in Europe, northern Africa, China, Korea, and the Philippines.

Discoglossid genera have been discovered from Jurassic deposits in Europe and represent some of the oldest frog fossils known. Included in the family are the fire-bellied toad (*q.v.*), with its brilliantly coloured underside, and the midwife toad (*q.v.*), noted for the peculiar reproductive behaviour of the male caring for the eggs.

Discordia (in Roman mythology): see Eris.

discount rate, also called **REDISCOUNT RATE**, or **BANK RATE**, interest rate charged by a central bank for loans of reserve funds to commercial banks and other financial intermediaries. This charge originally was an actual discount (an interest charge held out from the amount loaned), but the rate is now a true interest charge, even though the term discount rate is still used.

The discount rate serves as an important indicator of the condition of credit in an economy. Because raising or lowering the discount rate alters the banks' borrowing costs and hence the rates that they charge on loans, adjustment of the discount rate is considered a tool to combat recession or inflation. The discount rate also is used to deal with balance-of-payments deficits—that is, to regulate international movements of capital.

discount store, in merchandising, retail store that sells products at prices lower than those asked by traditional retail outlets. Some, like department stores, offer wide assortments of goods; others specialize in such merchandise as jewelry, electronic equipment, or electrical appliances. Food stores also have been operated on the discount principle. Stores that are open only to certain groups, such as cooperatives or government employees, are often known as closed-door discount stores.

Discount stores existed in the United States as early as the 1930s but matured only after World War II. They were successful because of the great postwar demand for consumer goods, because of their supermarket techniques, and because of the collapse of fair-trade laws that required distributors to sell at prices set by the manufacturers. Discount stores have spread worldwide, notably to western Europe, Latin America, Australia, and Japan.

Discoverer, any of a series of unmanned experimental satellites launched by the United States Air Force. Although the Discoverer satellites had several apparent applications—

such as testing orbital maneuvering and reentry techniques—they often are regarded as a forerunner of the military reconnaissance satellite. *Discoverer 1* (launched Feb. 28, 1959) was equipped with a camera and an ejectable capsule capable of carrying exposed film back to Earth. Like later reconnaissance satellites, it was placed in a low polar orbit. By orbiting almost directly over the poles, *Discoverer* was in position to photograph the entire surface of the Earth every 24 hours. All other satellites in the series were launched into a similar fixed orbit. The capsule ejection system was repeatedly tested, but in-air payload recovery was achieved only once during the early years of the program: the capsule released by *Discoverer 14* was retrieved on Aug. 18, 1960. *Discoverer 38* (launched Feb. 27, 1962) was the last Discoverer model to be officially announced.

discovery, in law, pretrial procedures providing for the exchange of information between the parties involved in the proceedings. Discovery may be made through interrogatories, which consist of sending written questions from one side to the other in an attempt to secure important facts; it also can be made through depositions, whereby a witness is sworn and, in the presence of attorneys for both sides, is subjected to questions. The written record of the proceedings also is called a deposition and may be introduced later if the case does come to trial. Other forms of discovery include order of production and inspection (by which the opposing party may be required to produce relevant documents or other evidence) and requests for medical examination (for cases in which a party's mental or physical condition is at issue).

Discovery Bay, wide curved bay indenting the south coast of Australia. An inlet of the Indian Ocean, it is 50 miles (80 km) across and is bounded on the east by Cape Bridgewater (Victoria) and on the west by Cape Northumberland (South Australia). Visited in 1800 by James Augustus Grant of the Royal Navy, it was named in 1836 by Thomas Livingstone Mitchell as he descended the Glenelg River (which enters the bay at Nelson). Settlement is sparse along the east shore but is dense around Port Macdonnell in the west.

discriminant, in mathematics, a parameter of an object or system calculated as an aid to its classification or solution. In the case of a quadratic equation $ax^2 + bx + c = 0$, the discriminant is $b^2 - 4ac$; for a cubic equation $x^3 + ax^2 + bx + c = 0$, the discriminant is $a^2b^2 + 18abc - 4b^3 - 4a^2c - 27c^2$. The roots of a quadratic or cubic equation with real coefficients are real and distinct if the discriminant is positive, real with at least two equal if the discriminant is zero, and include a conjugate pair of complex roots if the discriminant is negative. A discriminant can be found for the general quadratic, or conic, equation $ax^2 + bxy + cy^2 + dx + ey + f = 0$; it indicates whether the conic represented is an ellipse, a hyperbola, or a parabola.

Discriminants also are defined for elliptic curves, finite field extensions, quadratic forms, and other mathematical entities. The discriminants of differential equations are algebraic equations that reveal information about the families of solutions of the original equations.

discrimination, in psychology, the ability to perceive and respond to differences among stimuli. It is considered a more advanced form of learning than generalization (*q.v.*), the ability to perceive similarities, although animals can be trained to discriminate as well as to generalize.

Application of discrimination procedures permits description of the sensory acuities of laboratory animals. For example, if a dog's salivation response was to be conditioned to a red light by pairing it with food, while a green

light was intermittently presented always without food, the dog would salivate to red light but not to green. It then might be inferred that the dog discriminated between colours. If, however, the brightness of the green light was varied, a brightness would be discovered to which the dog salivated. No amount of additional discrimination training with red and green lights would lead to differential response. The conclusion would be that the dog is colour-blind (which, in reality, dogs are).

discus fish, two species of the genus *Symphysodon* of fishes in the family Cichlidae (order Perciformes), characterized by a compressed, disk-shaped body. The two species (*S. discus* and *S. aequifasciata*) occur naturally in tributaries of the Amazon River in South America. Discus fish have an unusual form of parental care: the adults secrete a mucus-like substance onto their skin that provides nourishment for the young. Some reports indicate that both parents are involved in the care of the young, taking turns "nursing the babies." Discus fish are difficult to keep in aquariums because of the strict water quality requirements necessary to keep them alive. Because of their spectacular wavy markings of blue and green, however, aquarium hobbyists persist in efforts to breed and raise them.

discus throw, track-and-field athletics sport of throwing a disk-shaped object known as a discus for distance. In modern competition the discus must be thrown from a circle 2.50 m (8 feet 2 1/2 inches) in diameter and fall within a 40° sector marked on the ground from the centre of the circle.

The sport was known in the days of the Greek poet Homer, who mentions it repeatedly, and it was one of five events included in the pentathlon in the ancient Olympic Games. Throwing the discus was introduced as an event in modern athletics when the Olympic Games were revived at Athens in 1896.

Early modern athletes threw the discus from an inclined pedestal, using an exaggerated style derived from ancient representations of the sport. Throwing from a 2.13-metre (7-foot) circle on the ground superseded this, and the circle was enlarged to its present size in 1912.

The modern throwing style is a graceful whirling movement, with the athlete making about one and a half quick turns while accelerating across the circle. Thus, the discus is slung out and not really thrown at all; the difficulty lies in controlling the discus, which is retained under and against the hand and wrist chiefly by centrifugal force.

The modern discus is circular, about 219–221 mm (8 5/8–8 3/4 inches) in diameter and 44 mm (1 3/4 inches) thick at its centre. It is made of wood or similar material, with a smooth metal rim and small, circular brass plates set flush into its sides. Its weight must be not less than 2 kg (4 pounds 6 1/2 ounces).

A discus event was included when women's track and field was added to the Olympic program in 1928. A slightly smaller discus weighing 1 kg (2 pounds 3 1/4 ounces) is used in women's events.

Notable discus throwers include American Al Oerter, who first broke the 61-metre (200-foot) mark; American Mac Wilkins, who was first to officially break the 70-metre (230-foot) mark; German Lisel Westermann, the first woman to break the 61-metre mark; and Russian Faina Melnik, who broke the 70-metre mark in women's competition. For world championship and World Cup winners, see Sporting Record: Athletics. For Olympic champions, see Olympic Games.

disease, an impairment of the normal state of an organism that interrupts or modifies its vital functions.

A brief discussion of disease follows. The subject is treated in a variety of MACROPAEDIA articles. For a general discussion of human,

animal, and plant diseases. *see* Disease. For a discussion of diseases categorized according to their cause or transmission, *see* Infectious Diseases; Nutrition; Occupational Diseases and Disorders. For a discussion of diseases associated with particular stages of human development, *see* Childhood Diseases and Disorders; Growth and Development, Biological. For a discussion of malignancy, which may affect any organ or tissue in the body, *see* Cancer. For a discussion of disease-causing organisms such as viruses, bacteria, and parasites, *see* Bacteria; Viruses. For a discussion of bodily defenses against disease, *see* Immunity. For a discussion of the diagnosis and treatment of disease, *see* Diagnosis and Therapeutics; Drugs and Drug Action; Medicine. For a discussion of diseases affecting particular organs, tissues, or processes, *see* Blood; Circulation and Circulatory Systems; Digestion and Digestive Systems; Endocrine Systems; Excretion and Excretory Systems; Integumentary Systems; Metabolism; Muscles and Muscle Systems; Nerves and Nervous Systems; Reproduction and Reproductive Systems; Respiration and Respiratory Systems; Sensory Reception; Supportive and Connective Tissues. For a discussion of neuroses and psychoses, *see* Mental Disorders and Their Treatment. For a discussion of alcoholism and other drug addictions, *see* Alcohol and Drug Consumption.

Disease most commonly is caused by the invasion of an organism by one or more outside agents. Typically the infectious organisms are microorganisms (*e.g.*, bacteria, viruses, and fungi), but they also can include larger organisms such as parasitic worms or nonliving but harmful substances such as toxins or ionizing radiation. Disease also may result from changes within the organism—an anatomical fault (congenital or acquired) or a physiological malfunction (*e.g.*, diabetes mellitus, in which the body fails to secrete or adequately utilize insulin, a hormone that regulates blood-sugar levels). Other diseases are a combination of external and internal factors. An organism's failure to adapt to changes in its environment can produce damaging changes within it. Physiological malfunctions and disturbances of normal growth can be induced by changes of diet or by invasion of microorganisms or other agents.

Nearly all organisms are able to defend themselves against most diseases. Humans and other vertebrates have developed two strategies of resistance, called immunity, to invading agents: nonspecific immunity, which is present in all vertebrates at birth; and specific immunity, which is acquired only after stimulation by the presence of a certain microbe or its products (*e.g.*, the virus that causes chicken pox). Immunity also can be stimulated artificially in humans or other animals by inoculating them with microorganisms that have been killed (as in typhoid vaccine) or weakened (attenuated) ones (as in measles vaccine), which produce the defensive immune reaction without causing the disease.

Sometimes an organism's defensive reaction to invasion by an outside agent can become part of the disease. The crippling of the lungs produced by tuberculosis is caused partly by the destruction of lung tissue by the invading microorganism (in humans, usually *Mycobacterium tuberculosis*) and partly by the fibrous tissue that the body lays around the infection in a defensive reaction. Disorders of the immune response itself can produce autoimmune disease (*e.g.*, rheumatoid arthritis) in which the immune response is triggered not by an outside invader but by the body's own tissues, which some cells fight against and try to reject. The immune system also can be disabled by an invading microorganism, as is the case with the disease AIDS.

Not all organisms that invade another produce disease. Some can establish a mutually beneficial relationship with their host without

impairing its vital systems; for example, the bacteria that live in the gastrointestinal tracts of humans and other vertebrates make possible the digestive processes of their hosts. In addition, organisms that are pathogenic to one species may be harmless to another.

A disease that becomes established in an organism usually requires some form of treatment. In most cases, treatment consists of administering drugs that kill the causative agent, restore any physiological or biochemical imbalances that have occurred, or control the symptoms caused by the agent so that the affected organism can continue to function. Other forms of treatment include moving the diseased organism to another environment or removing the diseased parts from the organism.

The most effective way to control disease is by preemptory prevention. The best method is to eliminate a disease-causing organism from the environment, such as by killing pathogens or parasites contaminating a water supply. Also effective is the disruption of a pathogen's transmission from one organism to another, either by avoiding contact with body tissues or fluids that harbour a pathogen or by eliminating an intermediary vector (*e.g.*, killing the mosquitoes that transmit malaria to humans). Disease also may be prevented by removing a susceptible organism from an unhealthful environment, strengthening the organism's defenses by making it healthier, or vaccination.

disease, occupational: *see* occupational disease.

dishcloth gourd, also called VEGETABLE SPONGE, SPONGE GOURD, LUFFA, or LOOFAH, any of six species of annual climbing vines constituting the genus *Luffa*, of the gourd family (Cucurbitaceae).

Dishcloth gourd (*Luffa cylindrica*)
A to Z Botanical Collection

Dishcloth gourds are native to the Old World tropics. Two species cultivated in temperate areas are *L. acutangula* and *L. aegyptiaca*. The cucumber-shaped fruits, edible and greenish when young, become straw-coloured with age. They are about 30 cm (1 foot) long and have closely netted vascular bundles (food- and water-carrying tubes), the complex of which resembles a sponge in texture when the skin, pulp, and seeds are removed. The resulting spongelike product is used domestically for bathing and for washing dishes and is used also as an industrial filter.

disilicate (mineralogy): *see* phyllosilicate.

disinfectant, any substance, such as creosote or alcohol, applied to inanimate objects to kill microorganisms. Disinfectants and antiseptics are alike in that both are germicidal, but antiseptics are applied primarily to living tissue. The ideal disinfectant would rapidly destroy bacteria, fungi, viruses, and protozoans, would

not be corrosive to surgical instruments, and would not destroy or discolour materials on which it is used.

disjunction, in logic, relation or connection of terms in a proposition to express the concept "or"; it is a statement of alternatives (sometimes called "alternation"). For clarity, exclusive disjunction (either x or y but not both), symbolized $x \vee y$, $x \vee\vee y$, or $x \neq y$, must be distinguished from inclusive disjunction (either x or y or both x and y), symbolized $x \vee y$. *See also* implication.

disk bat, also called DISK-WING BAT (genus *Thyroptera*), either of two species of bats constituting the family Thyropteridae, inhabiting Central America and northern South America. They are small, reddish brown bats, about 3.4 to 5.2 cm (1 to 2 inches) in length with tails about 2.4 to 3.3 cm long. Average weight is approximately 4 g (0.14 ounces).

Disk bats are distinguished by round pads at the base of the thumb and on the sole of the foot. These pads act as suction cups and enable the bats to cling to smooth, even glasslike, surfaces. One disk alone is capable of supporting the entire weight of the bat's body. Spix's disk bat (*T. tricolor*) lives in small, cohesive colonies and roosts in rolled-up leaves. It is unique among bats for its "heads-up" roosting posture.

disk jockey: *see* disc jockey.

Disko Island, Disko also spelled DISCO (Greenland): *see* Qcqaertarsuaq.

dislocation, in physiology and medicine, displacement of the bones forming a joint, with consequent disruption of tissues.

Dislocations are caused by stresses forceful enough to overcome the resistance of the ligaments, muscles, and capsule that hold the joint in place. A dislocation is called simple when the joint surfaces are not exposed to the air; it is called compound when the joint surfaces are exposed by the destruction of overlying skin or by the end of a bone piercing the skin.

A congenital dislocation is present at birth as the result of defective formation of the joint. A recurrent, or habitual, dislocation (repeated dislocation of the same joint) may be the result of improper healing of an old injury or may be natural, as in "double joints," common in fingers and toes, which are the result of loose ligamentation. A pathological dislocation occurs as the result of a disease, such as Marfan's syndrome, which weakens the capsule and ligaments about the joint.

Symptoms of dislocation include pain and tenderness at the site, a sensation of grating or grinding on attempting to use the part, and inability to use the part. Common signs are deformed appearance of the joint, swelling of surrounding tissue, and discoloration of the overlying skin. X-ray examination is useful to indicate the extent of the injury. Simple dislocations are treated by returning the bones to their normal position (reduction) by manipulation or occasionally by traction. The joint is then kept immobile until healing is complete. Recurrent and congenital dislocations are special problems that usually require surgical reconstruction of the joint.

Dismal Swamp, also called GREAT DISMAL SWAMP, marshy region on the Coastal Plain of southeastern Virginia and northeastern North Carolina, U.S., between Norfolk, Va., and Elizabeth City, N.C. It is densely forested and contains scattered natural elevations of 10 to 20 feet (3 to 6 m) above sea level. Along the western margin the Pamlico Formation (known as the Dismal Swamp Terrace) rises to 25 feet (7.5 m) and more, forming a natural boundary. The name Great Dismal was given

by Col. William Byrd of Virginia, who surveyed it in 1728. In 1763 George Washington, as a member of a surveying and engineering company, surveyed the area with a view to canalizing, draining, and reclaiming it. At that time the swamp was about 40 mi (65 km) long and covered about 2,000 sq mi (5,200 sq km). In the late 18th century 40,000 ac (16,000

Lake Drummond in the centre of Dismal Swamp, Virginia

By courtesy of the Virginia Department of Conservation and Economic Development

ha) were drained. The swamp is now about 37 mi long north to south and covers an area of approximately 750 sq mi. Despite much lumbering and widespread destruction of timber by fire, the area is still heavily wooded with cypress, black gum, juniper and water ash, and a tangle of honeysuckle and woodbine. The swamp is the habitat of many rare birds, including the ivory-billed woodpecker. The cottonmouth and other poisonous snakes are numerous. It is noted for fishing and hunting; deer, bear, raccoon, and opossum are plentiful, especially in the nearly inaccessible Coldwater Ditch area.

The Dismal Swamp Canal (built 1790–1828) is a 22-mi-long north-south intracoastal waterway connecting Chesapeake Bay, by way of Deep Creek and the southern branch of the Elizabeth River, with Albemarle Sound in North Carolina through the Pasquotank River. The canal forms a link in the Atlantic Intracoastal Waterway. In the midst of the swamp is the freshwater Lake Drummond (about 3 mi in diameter), which is connected with the canal by the 3-mi-long Feeder Ditch; this lake is the basis of the poem *The Lake of the Dismal Swamp*, by the Irish poet Thomas Moore.

Disney, Walt, byname of WALTER ELIAS DISNEY (b. Dec. 5, 1901, Chicago—d. Dec. 15, 1966, Los Angeles), U.S. motion-picture and television producer and showman, famous as a pioneer of animated cartoon films and as the creator of such cartoon characters as Mickey Mouse and Donald Duck. He also planned and built Disneyland, a huge amusement park that opened near Los Angeles in 1955, and before his death he had begun building a second such park, Walt Disney World, near Orlando, Fla. (opened 1971).

Early life. Walter Elias Disney was the fourth son of Elias Disney, a peripatetic carpenter, farmer, and building contractor, and his wife, Flora Call, who had been a public school teacher. When Walt was little more than an infant, the family moved to a farm near Marceline, Mo., a typical small Midwestern town, which is said to have furnished the inspiration and model for the Main Street U.S.A. of Disneyland. Here Walt began his

schooling and first showed a taste and aptitude for drawing and painting with crayons and watercolours.

His restless father soon abandoned his efforts at farming and moved the family to Kansas City, Mo., where he bought a morning newspaper route and compelled his young sons to assist him in delivering papers to home subscribers in rain or shine. Walt later said that many of the habits and compulsions of his adult life stemmed from the disciplines and discomforts of helping his father with the paper route. In Kansas City the young Walt began to study cartooning with a correspondence school and later took classes at the Kansas City Art Institute and School of Design.

In 1917 the Disneys moved back to Chicago, and Walt entered McKinley High, where he took photographs, made drawings for the school paper, and studied cartooning on the side, for he was hopeful of eventually achieving a job as a newspaper cartoonist. But his progress was interrupted by World War I, in which he participated as a truck driver for the American Red Cross in France and Germany.

Returning to Kansas City in 1919, he found occasional employment as a draftsman and inker in commercial art studios, where he met Ub Iwerks, a young artist who was to prove perhaps the most fortunate associate of his career after his brother Roy, who was his partner and strongest counsellor throughout life.

First animated cartoons. Dissatisfied with their progress, Disney and Iwerks started a small studio of their own and acquired a second-hand motion-picture camera with which they made one- and two-minute animated advertising films shown on local movie-theatre programs, such as commercials are shown on television today. They also did a series of animated cartoon sketches called "Laugh-O-Grams" and a series of seven-minute animated fairy tales, which they called "Alice in Cartoonland." A New York film distributor cheated the young producers, and, destitute and disheartened, Disney left for Los Angeles to join his brother Roy.

With Roy as business manager, Disney resumed the "Alice" series, persuading Iwerks to join him and assist with the drawing of the cartoons. They invented a character called Oswald the Rabbit, contracted for distribution of the films at \$1,500 each, and propitiously launched their small enterprise. Just before the transition to sound in motion pictures in 1927, Disney and Iwerks experimented with a new character—a cheerful, energetic, and mischievous mouse called Mickey. They planned two shorts, called *Plane Crazy* and *Gallopin' Gaucho*, that were to introduce Mickey Mouse when *The Jazz Singer*, a motion picture with the popular singer Al Jolson, brought the novelty of sound to the movies. Fully recognizing

the possibilities for sound in animated-cartoon films, Disney quickly produced a third Mickey Mouse cartoon equipped with voices and music, entitled *Steamboat Willie*, casting the other two soundless cartoon films aside. When it appeared in 1928, *Steamboat Willie* was a sensation.

The following year Disney started a new series called "Silly Symphonies" with a picture entitled *The Skeleton Dance*, in which a skeleton rose from the graveyard and did a grotesque, clattering dance to the music of Saint-Saëns's *Danse macabre*. Original and briskly syncopated, the film launched the series most successfully, but, with costs mounting because of the more complicated drawing and technical work, Disney's operation was continually in peril.

The growing popularity of Mickey Mouse and his girl friend, Minnie, however, attested to the public's taste for the fantasy of little creatures with the speech, skills, and personality traits of human beings. (Disney himself provided the voice for Mickey.) This popularity led to the invention of other animal characters; such as Donald Duck and the dogs Pluto and Goofy. In 1933 Disney produced a short, *The Three Little Pigs*, which arrived in the midst of the Great Depression and took the country by storm. Its treatment of the fairy tale of the little pig who works hard and builds his house of brick against the huffing and puffing of a threatening wolf suited the need for fortitude in the face of economic disaster, and its song "Who's Afraid of the Big Bad Wolf" was a happy taunting of adversity. It was in this period of economic hard times in the early 1930s that Disney fully endeared himself and his cartoons to audiences all over the world, and his operation began making money in spite of the Depression.

Through successive additions and advances in the animated-cartoon field, Disney continued to progress all through the 1930s. He had now gathered a staff of creative young people, who were headed by Iwerks. Colour was introduced in the "Silly Symphony" film *Flowers and Trees* (1932), while other animal characters came and went in films such as *The Grasshopper and the Ants* (1934) and *The Tortoise and the Hare* (1935). Roy franchised tie-in sales with the cartoons of Mickey Mouse and Donald Duck—watches, dolls, shirts, and tops—and reaped more wealth for the company.

Feature-length cartoons. Walt Disney was never one to rest or stand still. He had long thought of producing feature-length animated films in addition to the shorts. In 1935 he began work on a version of the classic fairy tale that he called *Snow White and the Seven Dwarfs*, a project that required great organization and coordination of the creative and technical talents in his studio. Disney possessed a unique taste and capacity for such a task. While he actively engaged in all phases of creation in his films, he functioned chiefly as coordinator and final decision maker rather than as designer and artist. *Snow White* was widely acclaimed by critics and audiences alike as an amusing and sentimental romance. By animating substantially human figures in the characters of Snow White, the Prince, and the Wicked Queen and by forming caricatures of human figures in the seven dwarfs, Disney departed from the scope and techniques of the shorts and thus made a momentous transition in the nature of his type of film. While he continued for a while to do short films presenting the anthropomorphic characters of his little animals, he was henceforth to develop a wide variety of full-length entertainment films.

Snow White was followed three years later by other feature-length classics for children, *Pinochio* (1940) and *Dumbo* (1941), the story of an elephant that could fly; and then Disney produced another totally unusual and exciting film—his multisegmented and stylized *Fanta-*

Walt Disney
EB Inc

sia (1940), in which cartoon figures and colour patterns were made to move to the music of Igor Stravinsky, Paul Dukas, Peter Ilich Tchaikovsky, and others. In 1940 Disney moved his company into a new studio in Burbank, Calif., abandoning the old plant it had occupied in the early days of growth.

Major films and television productions. During World War II the Disney studio did work for the military and the federal government, in the course of which it perfected the methods of combined live action and cartoon. Disney also made many commercial films with these hybrid techniques: *The Reluctant Dragon* (1941), *Saludos Amigos* (1942), *The Three Caballeros* (1944), *Make Mine Music* (1946), and *Song of the South* (1946).

The Disney studio was now established as a big-business enterprise and began to produce a variety of entertainment films. One popular series, called *True-Life Adventures*, featured such nature-based motion pictures as *Seal Island* (1948), *Beaver Valley* (1950), and *The Living Desert* (1953). The Disney studio also began making full-length animation romances, such as *Cinderella* (1950), *Alice in Wonderland* (1951), and *Peter Pan* (1953), and produced low-budget, live-action films, including *The Absent-Minded Professor* in 1961.

The Disney studio was among the first to foresee the potential of television as a popular-entertainment medium and to produce films directly for it. The *Zorro* and *Davy Crockett* series were very popular with children, and *Walt Disney's Wonderful World of Color* became a continuing television fixture. But the climax of Disney's career as a theatrical film producer came with his release in 1964 of the motion picture *Mary Poppins*, which won worldwide popularity.

Disneyland. Meanwhile, back in the early 1950s, Disney had initiated plans for a huge amusement park to be built near Los Angeles. When Disneyland opened in 1955, much of Disney's disposition toward nostalgic sentiment and fantasy was evident in its design and construction. It soon became a mecca for tourists from all over the world. A second Disney park, Walt Disney World, near Orlando, Fla., which was under construction at the time of his death, opened in 1971.

Assessment. Disney's imagination and energy, his whimsical humour, and his gift for being attuned to the vagaries of popular taste inspired him to develop well-loved amusements for "children of all ages" throughout the world. His achievement as a creator of entertainment for an almost unlimited public and as a highly ingenious merchandiser of his wares may be compared to that of a successful industrialist.

(B.Cr./Ed.)

BIBLIOGRAPHY. Richard Schickel, *The Disney Version*, rev. and updated ed. (1985), is a definitive biography. Christopher Finch, *The Art of Walt Disney: From Mickey Mouse to the Magic Kingdoms* (1973), recounts Disney's life and the corporate growth of Walt Disney Productions. Frank Thomas and Ollie Johnston, *Disney Animation: The Illusion of Life* (1981), by two former Disney animators, surveys the techniques used in making an animated feature film.

Disney Company, in full THE WALT DISNEY COMPANY, formerly (1929–86) WALT DISNEY PRODUCTIONS, American corporation that became the best-known purveyor of child and adult entertainment in the 20th century. Its headquarters are in Burbank, Calif.

The company was founded by the motion-picture animator Walt Disney and his businessman brother Roy in 1929 under the name Walt Disney Productions to incorporate the brothers' studio, which produced animated motion-picture cartoons. Disney cartoons featuring Mickey Mouse, Minnie Mouse, Donald Duck, and Pluto achieved wide popularity in the United States in the 1930s, and their success encouraged the company to produce *Snow White and the Seven Dwarfs* (1937), the

first feature-length animated cartoon. *Snow White* was followed by several other feature-length cartoons that are now regarded as classics of animation, among them *Dumbo* (1940), *Fantasia* (1940), and *Cinderella* (1950).

When the rising labour costs of animation in the late 1940s began to make full-length animated cartoons too expensive to produce, the Disney company began making nature documentaries and live-action motion pictures, as well as short cartoons and live-action programs for television. In 1955 the company opened the Disneyland amusement park, one of the world's most famous, in Anaheim, Calif. The park has different sections devoted to specific themes. A second and larger amusement complex, Walt Disney World, was opened near Orlando, Fla., in 1971. Besides containing the Epcot Center and Magic Kingdom theme parks, Disney World contains hotels, resort accommodations, and sports and other recreational facilities.

The Disney corporation declined after Walt Disney's death in 1966 deprived the company of its chief innovator. The company was revitalized under new management in the 1980s, however, and its motion-picture and animated-film production units became among the most successful in the United States. Touchstone Films, a company formed in 1984 to produce films outside of the usual Disney type, proved especially successful with comedies and romances such as *Splash* (1984) and *Pretty Woman* (1990). The Disney Company returned to feature-length animated cartoons with *The Little Mermaid* (1989) and went on to make *Toy Story* (1995), the first full-length computer-animated cartoon.

In 1983 an unrelated Japanese corporation opened Tokyo Disneyland near Tokyo, with the Walt Disney Company receiving royalties from that venture. In 1992 the Disney Company itself completed the building of Euro Disneyland at Marne-la-Vallée, 20 miles (32 km) east of Paris. In 1996 the Disney corporation acquired Capital Cities/ABC Inc., which owned the ABC television network. The Disney Company also operates the Disney Channel, a pay television programming service. *See also* Disney, Walt.

disorderly conduct, in law, intentional disturbing of the public peace and order by language or other conduct. It is a general term including various offenses that are usually punishable by minor penalties.

Disorderly conduct may take the form of directly disturbing the peace, as when one intentionally disrupts a public meeting or awakens a sleeping community. Less directly, it includes fighting in a public place, although it does not apply to one who defends himself on being attacked. Most jurisdictions penalize displays of public drunkenness. Some maintain vagrancy statutes that penalize persons found to be idle and without visible means of support. These may include prostitutes, beggars, gamblers, or alcoholics.

dispensation, also called **ECONOMY**, in Christian ecclesiastical law, the action of a competent authority in granting relief from the strict application of a law. It may be anticipatory or retrospective.

Economy is the term that is normally employed in the Eastern Orthodox churches for this type of action. The church strives for the salvation of souls, and, when this is more likely to be achieved by a relaxation of a rule rather than by a strict adherence to it, economy permits the relaxation. With typical Orthodox elasticity, no canon defines the limits or use of economy, although certain broad principles are discernible. Thus, to run counter to fundamental dogma is permissible when this is conducive to the greater good of the church and the salvation of souls. Lack of precision is also found with regard to the persons who may exercise economy. All bish-

ops exercise it in their own right and not by delegation; but they should have regard to the views of episcopal synods, which themselves exercise economy, although only after consultation with the bishop of the district within which it is to be exercised. Above both the bishop and the synod is the general council, which has the authority to exercise economy of its own and can reverse the decisions of synods and bishops. Below the bishop is the priest, who exercises economy in day-to-day matters but whose authority is delegated to him by the bishop.

The Western Christian churches have evolved rules with regard to dispensation with far greater precision and, in the Roman Catholic church, in some detail. At first, it was held that only the common good of the church as a whole justified the granting of a dispensation and that only the person or body that made the laws, whether pope, synod, or bishop, could dispense from them. With the development of canon law and the growth of the power of the papacy, however, it came to be accepted that the ultimate dispensing power resided in the pope, though it could be delegated by him to subordinate persons and bodies. The field over which dispensation could operate was significantly widened, for, whereas formerly the divine law and the natural law were outside the scope of the dispensing power, the view was gradually reached that the jurisdiction of the pope, while unable to abrogate the divine or the natural law, could nevertheless dispense from the obligations imposed by them and from their effects in particular cases, though only where the ultimate object of such laws was not thereby thwarted.

Gradually, dispensations were granted solely for the benefit of individuals, regardless of whether or not the whole church could be said to benefit thereby, and the belief that such dispensations were granted too frequently and for financial gain was a factor contributing to the movement that led to the Protestant Reformation. The Council of Trent (1545–63) tried to guard against abuses but left intact the papal authority, and the Roman Catholic system of dispensation today is essentially the same as that which had developed by the end of the Middle Ages. While the authority that has the power to legislate may dispense from its own legislation, so also may its superior; and the subordinate authority's power may be limited by superior authority. The ultimate authority resides in the pope.

In England, the Reformation, which was inspired at least in part by the pope's refusal to grant Henry VIII a dispensation from his marriage to Catherine of Aragon, put an end to the papal authority in this and all other spheres of its previous jurisdiction. The need for a dispensing authority was, however, recognized, and a statute in 1534 preserved the bishops' dispensational powers and conferred upon the archbishop of Canterbury the power of dispensing formerly exercised by the pope, subject in the more important cases to royal confirmation. These provisions, however, have remained largely a dead letter, with the consequent lack of any ordered, practical system of dispensation in the Church of England.

dispersion, in biology, the dissemination, or scattering, of organisms over periods within a given area or over the Earth.

The two disciplines most intimately intertwined with the study of dispersion are systematics and evolution. Systematics is concerned with the relationships between organisms and includes the classification of life into ordered groups, providing the detailed information essential to all biology. The study of evolution grew from a combination of systematics and dispersion, or distribution, as both Charles

Darwin and Alfred Russel Wallace, pioneers in evolutionary biology, attested; and, in turn, an understanding of the process of natural selection has illuminated the reasons for changes in distribution in the history of the Earth.

A specific type of organism can establish one of three possible patterns of dispersion in a given area: a random pattern; an aggregated pattern, in which organisms gather in clumps; or a uniform pattern, with a roughly equal spacing of individuals. The type of pattern often results from the nature of the relationships within the population. Social animals, such as chimpanzees, tend to gather in groups, while territorial animals, such as birds, tend to assume uniform spacing. Close attention must be paid to the scale of study in order to get an accurate reading of these patterns. If a group of monkeys occupies three widely separated trees, their spacing will obviously be aggregate; yet in each tree, their spacing may appear to be uniform.

Distribution can be affected by time of day, month, or year. The most common form of distributional change occurs among migratory animals, which may be plentiful in the summer months and virtually absent in the winter. The forces governing the dispersal of organisms are either vectorial (directed motion), that is, caused by wind, water, or some other environmental motion, or stochastic (random), as in the case of the change in seasons, which gives no indication of where the dispersing organisms may ultimately settle. Dispersion may also be affected by the interrelationship of species with one another or with nutrients. Competition between species that depend on the same food types often leads to the elimination of one species, just as the extent of plant life often determines the boundaries of a species' territory.

The irregularities of most distribution patterns are simplified in the case of life forms dependent upon relatively restricted habitats, like that of intertidal mollusks, which have an almost linear distribution along rocky sea-coasts. A few species, most notably humans and the animals dependent upon them, have a worldwide distribution.

Among both plants and animals, dispersal usually takes place at the time of reproduction. When overcrowding forces individuals to range outside the area in which they were born to find a mate or food, new populations occasionally arise. Insects often display distinctive abilities in this regard. East African locusts have been found in two forms, a bright green variety, which is sluggish and solitary, and a highly mobile, group-oriented, dark-coloured form that swarms in enormous numbers, eating all plant material in its path. It has been found that if the young of the green variety are raised in large, constricted groups, they metamorphose into the dark form at maturity. This is called phase polymorphism. As their numbers increase and the food supply thins, the locusts undergo developmental and behavioral changes to produce the widest dispersion pattern possible.

Occasionally, natural selection acts to limit the dispersal of a species. On high mountaintops and isolated islands, for example, the predominance of flightless birds and insects is notable.

Organisms are also spread by passive means, such as wind, water, and by other creatures. This method is hardly less effective than active dispersal; spiders, mites, and insects have been collected by airplanes over the Pacific as much as 3,100 km (about 1,900 miles) from land. Plants regularly spread their seeds and spores by the action of the wind and water, often with morphological adaptations to increase their potential range, as in the case of milkweed seeds.

Seeds are also spread by animals, often as undigested matter in the excrement of birds or mammals, or by attaching to animals via an assortment of hooks, barbs, and sticky substances. Parasites regularly use either their hosts or other creatures as distribution mechanisms. The myxoma virus, a parasite in rabbits, is carried by mosquitoes, which may travel as far as 64 km (40 miles) before infecting another rabbit.

Mountains and oceans can be effective barriers to the dispersal of organisms, as can stretches of desert or other climatological extremes. Some organisms can cross these barriers; birds can cross the English Channel, while bears cannot. In such cases, the paths of the more mobile animals are called filter routes.

Over geologic ages there have been many dramatic changes in climate that have affected distribution and even the survival of many life forms. Furthermore, the continents appear to have undergone large-scale displacements (*see* continental drift), separating many species and encouraging their independent development. But the greatest factor in the dispersal of organisms, at least during the past 10,000 years, has been human influence.

dispersion, in wave motion, any phenomenon associated with the propagation of individual waves at speeds that depend on their wavelengths. Ocean waves, for example, move at speeds proportional to the square root of their wavelengths; these speeds vary from a few feet per second for ripples to hundreds of miles per hour for tsunamis. A wave of light has a speed in a transparent medium that varies inversely with the index of refraction (a measure of the angle by which the direction of a wave is changed as it moves from one medium into another). Any transparent medium—*e.g.*, a glass prism—will cause an incident parallel beam of light to fan out according to the refractive index of the glass for each of the component wavelengths, or colours. Dispersion is sometimes called the separation of light into colours, an effect more properly called angular dispersion.

displacement, in mechanics, distance moved by a particle or body in a specific direction. It is a vector quantity, possessing both magnitude and direction. In the Figure, A is the ini-

Displacement

tial position of a point, B is the final position, and the vector directed from A to B is the displacement. The distance traveled by the point depends on the path that it follows; it will be equal to the magnitude of the displacement only if the path is straight. In mechanics, it is frequently necessary to distinguish between the distance that a point moves—or through which a force acts—and the displacement of the point or the force.

displacement, electric: *see* electric displacement.

displacement activity, the performance by an animal of an act inappropriate for the stimulus or stimuli that evoked it. Displacement

behaviour usually occurs when an animal is torn between two conflicting drives, such as fear and aggression. Displacement activities often consist of comfort movements, such as grooming, scratching, drinking, or eating. In courtship, for example, an individual afraid of its mate may, instead of fleeing or courting, stand still and feed or groom itself.

displacement current, in electromagnetism, a phenomenon analogous to an ordinary electric current, posited to explain magnetic fields that are produced by changing electric fields. Ordinary electric currents, called conduction currents, whether steady or varying, produce an accompanying magnetic field in the vicinity of the current. The British physicist James Clerk Maxwell in the 19th century predicted that a magnetic field also must be associated with a changing electric field even in the absence of a conduction current, a theory that was subsequently verified experimentally. As magnetic fields had long been associated with currents, the predicted magnetic field also was thought of as stemming from another kind of current. Maxwell gave it the name displacement current, which was proportional to the rate of change of the electric field that kept cropping up naturally in his theoretical formulations.

As electric charges do not flow through the insulation from one plate of a capacitor to the other, there is no conduction current; instead, a displacement current is said to be present to account for the continuity of the magnetic effects. In fact, the calculated size of the displacement current between the plates of a capacitor being charged and discharged in an alternating-current circuit is equal to the size of the conduction current in the wires leading to and from the capacitor. Displacement currents play a central role in the propagation of electromagnetic radiation, such as light and radio waves, through empty space. A traveling, varying magnetic field is everywhere associated with a periodically changing electric field that may be conceived in terms of a displacement current. Maxwell's insight on displacement current, therefore, made it possible to understand electromagnetic waves as being propagated through space completely detached from electric currents in conductors.

displacement law, in physics, any of the statements (originally formulated in 1913) that radioactive decay produces daughter atoms whose position in the periodic table of the chemical elements is shifted from that of their parents: two lower for alpha decay and one higher for negative beta decay. *See* radioactive series.

display behaviour, ritualized behaviour by which an animal provides specific information to others, usually members of its own species. Virtually all higher animals use displays to some extent. The best-known displays are visual ones—and some biologists restrict the term display to visual signals or gestures—but many also incorporate sound, smell, or even touch. Displays evolve through the ritualization of specific behaviour patterns. Some mating displays evolve from food-giving behaviours; the male bobwhite quail gives a food call and offers a tidbit to his potential mate. In many birds the food-giving behaviour is completely ritualized and proceeds without any exchange of food; domestic cocks, for example, call and peck at bare ground to attract a hen.

Agonistic (aggressive) displays usually occur near the borders of a territory. When a strange howler monkey approaches the territory of others, resident males set up a tremendous din, warning the intruder off. Many songbirds sit on highly visible perches while singing, providing both auditory and visual displays. Agonistic display is adaptive in conserving energy, making it unnecessary for the resident animal

to chase others away. Furthermore, where display occurs, injury is rare, as physical contact is rarely required. An impending threat to the group may provoke display behaviour that is protective, signaling danger at the approach of a predator.

Another type of display behaviour is that designed to deceive a predator or lure it away from vulnerable young. An example is the broken-wing display—where the parent flutters along the ground as if injured—used by many birds to lure predators away from the nests. *See also* alarm signal; courtship; territorial behaviour.

disposable income, that portion of an individual's income over which the recipient has complete discretion. An accurate general definition of income is not easy to provide. Income includes wages and salaries, interest and dividend payments from financial assets, and rents and net profits from businesses. Capital gains on real or financial assets should also be counted as income in most cases, at least insofar as they increase spending power. Such gains may even be counted where the asset is not actually sold and the increase in spending power is not exercised. In addition, receipts not in the form of cash—income in kind—may be included.

Disposable income involves a further adjustment to exclude obligatory payments in the form of direct taxes, compulsory payments to social-insurance schemes, and the like and to include simple transfers from other persons, institutions, or the government such as social-security benefits, pensions, and alimony. In some cases the boundary between voluntary and obligatory payments is blurred so that the meaning of disposable income becomes ambiguous. Also, a distinction may have to be made between transfer income to which a person is entitled and that which is actually received.

By convention, indirect taxes, such as value-added and other sales taxes, payroll taxes, and employers' contributions to social insurance, are not deducted from the computation of disposable income. Although these clearly reduce private spending power generally, it is difficult to attribute their incidence to specific persons and families. It should also be noted that when members of families or other units share in a "pool" of income, there may be a substantial divergence between a person's nominal disposable income (as recorded, for example, on his paycheck) and his actual discretionary spending power. Thus, a person who appears in official statistics as having a very low after-tax income may in fact be a part-time worker contributing to, and sharing in, his family's joint resources.

To compare flows of disposable income at different points in time, in different countries, or even in different locations within a country, the measured values of such incomes must be adjusted to allow for variations in the cost of living. Even after such adjustments have been made, disposable income should not be confused with standard of living (*q.v.*) or with economic welfare, the actual standard of consumption that a person has achieved.

Disraeli, Benjamin, EARL OF BEACONSFIELD, VISCOUNT HUGHENDEN OF HUGHENDEN, byname DIZZY (b. Dec. 21, 1804, London, Eng.—d. April 19, 1881, London), British statesman and novelist who was twice prime minister (1868, 1874–80) and who provided the Conservative Party with a twofold policy of Tory democracy and imperialism.

Early life. Disraeli was of Italian-Jewish descent, the eldest son and second child of Isaac D'Israeli and Maria Basevi. The most important event in Disraeli's boyhood was his father's quarrel in 1813 with the synagogue of Bevis Marks, which led to the decision in 1817 to have his children baptized as Christians. Until 1858 Jews by religion were excluded

Disraeli, albumen print by W. & D. Downey

from Parliament; except for the father's decision Disraeli's political career could never have taken the form it did.

Disraeli was educated at small private schools. At the age of 17 he was articled to a firm of solicitors, but he longed to become notable in a more sensational manner. His first efforts were disastrous. In 1824 he speculated recklessly in South American mining shares, and, when he lost all a year later, he was left so badly in debt that he did not recover until well past middle age. Earlier he had persuaded the publisher John Murray, his father's friend, to launch a daily newspaper, the *Representative*. It was a complete failure. Disraeli, unable to pay his promised share of the capital, quarreled with Murray and others. Moreover, in his novel *Vivian Grey* (1826–27), published anonymously, he lampooned Murray while telling the story of the failure. Disraeli was unmasked as the author, and he was widely criticized.

Disraeli suffered what would later be called a nervous breakdown and did little during the next four years. He wrote another extravagant novel, *The Young Duke* (1831), and in 1830 began 16 months of travel in the Mediterranean countries and the Middle East. These travels not only furnished him with material for Oriental descriptions he used in later novels but also influenced his attitude in foreign relations with India, Egypt, and Turkey in the 1870s.

Back in England, he was active in London social and literary life, where his dandified dress, conceit and affectation, and exotic good looks made him a striking if not always popular figure. He was invited to fashionable parties and met most of the celebrities of the day. His novel *Contarini Fleming* (1832) has considerable autobiographical interest, like many of his novels, as well as echoes of his political thought.

Political beginnings. By 1831 Disraeli had decided to enter politics and sought a seat in Buckinghamshire, near Wycombe, where his family had settled. As an independent radical, he stood for and lost High Wycombe twice in 1832 and once in 1835. Realizing that he must attach himself to one of the political parties, he made a somewhat eccentric interpretation of Toryism, which some features of his radicalism fitted. In 1835 he unsuccessfully stood for Taunton as the official Conservative candidate. His extravagant behaviour, great debts, and open liaison with Henrietta, wife of Sir Francis Sykes (the prototype of the heroine in his novel *Henrietta Temple* [1837]), all gave him a dubious reputation. In 1837, however, he successfully stood for Maidstone in Kent as the Conservative candidate. His maiden speech in the House of Commons was a failure. Elaborate metaphors, affected mannerisms, and foppish dress led to his being shouted down. But he was not silenced. He

concluded, defiantly and prophetically, "I will sit down now, but the time will come when you will hear me."

Before long, Disraeli became a speaker who commanded attention. He established his social position by marrying in 1839 Mrs. Wyndham Lewis, a widow with a life interest in a London house and £4,000 a year. She was deeply devoted to Disraeli, and when he teased her in company that he had married for her worldly goods, she would say: "Dizzy married me for my money but if he had the chance again he would marry me for love." Her husband agreed.

Breach with Peel. The Conservative leader, Sir Robert Peel, encouraged Disraeli, but when in 1841 the Conservatives won the election and Peel became prime minister, Disraeli was not given office in the Cabinet. He was mortified at the rebuff, and his attitude toward Peel and his brand of Conservatism became increasingly critical. A group of young Tories, nicknamed Young England, and led by George Smythe (later Lord Stangford), looked to Disraeli for inspiration, and he obliged them, notably in his novel *Coningsby; or The New Generation* (1844), in which the hero is patterned on Smythe, and the cool, pragmatic, humdrum, middle-class Conservatism that Peel represented is contrasted to Young England's romantic, aristocratic, nostalgic, and escapist attitude.

In 1845, when the combination of the Irish famine and the arguments of Richard Cobden convinced Peel to repeal the protective duties on foreign imported grain known as the Corn Laws, Disraeli found his issue. Young England could rally against Peel not only their own members but the great mass of the country squires who formed the backbone of the Conservative Party. As lieutenant to Lord George Bentinck, the nominal leader of the rebels, Disraeli consolidated the opposition to Peel in a series of brilliant speeches. His invective greatly embittered the battle and created lasting resentment among Peel's followers. While Disraeli and his fellow protectionists could not stop the repeal of the Corn Laws because the Whigs also backed the bill, the rebels put Peel in the minority on another issue and forced him to resign in 1846.

Conservative leader. The loyalty of most of the Conservative former ministers to Peel and the death of Bentinck made Disraeli indisputably the leader of the opposition in the Commons. Disraeli spent the next few years trying to extricate his party from what he had come to recognize as the "hopeless cause" of protection. While Disraeli's policy was sensible, it raised mistrust among his followers, as did his pride in and insistence upon his Jewish ancestry. The party could not, however, do without his talents. His election to Parliament as member for Buckinghamshire in 1847 and his purchase of Hughenden Manor, near High Wycombe, in 1848 fortified his social and political power. His finances, however, remained shaky.

When the Whig government fell in 1852 and the Earl of Derby, leader of the Conservative Party, formed a short-lived minority government, Disraeli was chancellor of the Exchequer despite his protest that he knew nothing of finance. His budget in fact brought the government down in 1852, though Disraeli could hardly be blamed. The free-trade majority in the House was determined to defeat measures that relieved agriculture, even though the method chosen did not involve protection; yet Disraeli had to bring forward some such proposals to placate his followers. Again, until 1858, the Tories were in opposition. Then Derby again formed a minority government with Disraeli as chancellor of the Exchequer. Disraeli for some time had felt

there was no reason to allow parliamentary reform to be a Whig monopoly, and so he introduced a moderate reform bill in 1859. The bill, however, seemed too obviously designed to help his party, and so it was defeated; the Tories again were out of office and remained so for six years.

In 1865 when the Whig-Liberal leader Lord Russell brought forward a moderate reform bill, a combination of Tory opposition and a revolt against Russell toppled his government. Derby formed his third minority government with Disraeli as chancellor of the Exchequer. Although the initiative for a new Conservative reform bill came from Queen Victoria and Lord Derby, Disraeli introduced it in the House and conducted the fight for it with unsurpassed enthusiasm and mastery of parliamentary tactics. He believed the bill should be a sweeping one with certain safeguards, and he was determined that it should be carried by a Conservative government. The Liberals, however, had a majority, and he had to accept their amendments, which removed nearly all the safeguards. The bill that passed doubled the existing electorate and was more democratic than most Conservatives had foreseen. Derby called it "a leap in the dark"; but Disraeli could fairly claim that the bill had gone far toward "realizing the dream of my life and re-establishing Toryism as a national foundation."

The "top of the greasy pole." In 1868 when Derby retired from politics, Disraeli became prime minister. "Yes," he said in reply to a friend's congratulations, "I have climbed to the top of a greasy pole." The government was only a caretaker one, for the general election awaited only the completion of a new electoral register, and later in 1868 the Liberals won. Disraeli set a precedent by resigning before Parliament met.

In the following 12-year period, politics changed from the chaotic collection of ill-defined, shifting groups that had been common from the beginning of Disraeli's career. Now the old politics defined by personalities shifted to an emergence of two parties with coherent policies. The party leaders, Disraeli and William E. Gladstone, were implacable enemies, and they polarized the parties.

At first Disraeli played a comparatively peaceful role. He tried to create a new image for the Conservative Party that he hoped would persuade the new electorate. His seeming apathy disturbed his followers, and his novel *Lothair* (3 vol., 1870), a political comedy, seemed to some of them undignified.

From 1872, however, Disraeli ran the party with a firm hand. He sharply differentiated Conservative from Liberal policy on several issues: he defended the monarchy, the House of Lords, and the church against what he took to be the threat of radical Liberal policy; he put forth a policy to consolidate the empire, with special emphasis on India; he dwelt on social reform; he enunciated a strong foreign policy, especially against Russia.

In 1872 Disraeli's wife died of cancer after many months of illness. Her death brought material losses: her house in London and her fortune passed to cousins. At age 68 his health was not good, but he turned implacably to political battle. He began a romantic friendship with two sisters, Lady Bradford and Lady Chesterfield, with whom he corresponded on politics and his personal feelings until his death.

His political fortunes turned when Gladstone's ministry was defeated in 1873. When Gladstone resigned, Disraeli refused to take office, pleading there was too much uncompleted business to dissolve Parliament, and that a minority government could only damage his party's prospects. Gladstone reluc-

tantly returned to office, but within a year he dissolved the Parliament himself. Disraeli had been at work on party organization and electoral machinery, and the Conservatives won a resounding victory in 1874.

Second administration. Disraeli gained power too late. He aged rapidly during his second ministry. But he formed a strong Cabinet and profited from the friendship of the Queen, a political conservative who disliked Gladstone. Disraeli treated her as a human being, whereas Gladstone treated her as a political institution.

In regard to social reform, Disraeli was able at last to show that Tory democracy was more than a slogan. The Artizans' and Labourers' Dwellings Improvement Act made effective slum clearance possible. The Public Health Act of 1875 codified the complicated law on that subject. Equally important were an enlightened series of factory acts (1874, 1878) preventing the exploitation of labour and two trades union acts that clarified the legal position of those bodies.

Disraeli's imperial and foreign policies were even more in the public eye. His first great success was the acquisition of Suez Canal shares. The extravagant and spendthrift khedive Isma'il Pasha of Egypt owned slightly less than half the Suez Canal Company's shares and was anxious to sell. An English journalist discovered this fact and told the Foreign Office. Disraeli overrode its recommendation against the purchase and bought the shares using funds provided by the Rothschild family until Parliament could confirm the bargain. The deal was seen as a notable triumph for imperial prestige. Early in 1876 Disraeli brought in a bill conferring on Queen Victoria the title empress of India. There was much opposition, and Disraeli would have gladly postponed it, but the Queen insisted. For some time his poor health had made leading the Commons onerous, so he accepted a peerage, taking the title earl of Beaconsfield, and became leader in the House of Lords.

Foreign policy largely occupied him until 1878. The Russian-Turkish conflict had lain dormant since the Crimean War in the 1850s, but Christian subjects of the Ottoman Empire revolted against intolerable misrule. Russia declared war on Turkey in 1877 and reached the gates of Constantinople early in 1878. Britain feared for the safety of the route to India, but Disraeli correctly judged that a show of force would be enough to bring the exhausted Russian forces to terms. The highly Pan-Slavist Treaty of Stefano forced on Turkey by Russia had to be submitted to a European Congress at Berlin in 1878. Beaconsfield attended and won all concessions he wanted. He returned to London in triumph, declaring that he had brought back "peace with honour."

At this climax of his career, the Queen offered him a dukedom, which he refused, and the Order of the Garter, which he accepted. Thereafter his fortunes waned with disaster in Afghanistan, forces slaughtered in South Africa, agricultural distress, and an industrial slump. The Conservatives were heavily defeated in the general election of 1880. Beaconsfield kept his party leadership and finished *Endymion* (3 vol., 1880), a mellow, nostalgic political novel viewing his early career. His health failed rapidly, and a few days after his burial in the family vault at Hughenden, Queen Victoria came to lay a wreath upon the tomb of her favourite prime minister.

A popular biography is Hesketh Pearson, *Dizzy* (1951). For his early life, see B.R. Jerman, *The Young Disraeli* (1960). A good short life is Harold Beoley, *Disraeli* (1936). Richard A. Levine, *Benjamin Disraeli* (1968), is a study of the novels, particularly *Coningsby*, *Sybil*, and *Tancred*; Daniel R. Schwarz, *Disraeli's Fiction* (1979), is a positive criticism of his works.

dissociation, in chemistry, the breaking up of a compound into simpler constituents that are usually capable of recombining under other conditions. In electrolytic, or ionic, dissociation, the addition of a solvent or of energy in the form of heat causes molecules or crystals of the substance to break up into ions (electrically charged particles). Most dissociating substances produce ions by chemical combination with the solvent. The idea of ionic dissociation is used to explain electrical conductivity and many other properties of electrolytic solutions.

dissonance (music): see consonance and dissonance.

distance-measuring equipment (DME), in aerial navigation, equipment for measuring distance by converting the time a special electronic pulse takes to travel from an aircraft to a ground station and for an answering pulse to return. The airborne equipment displays the information to the pilot. When used in connection with a radio-range bearing, which indicates direction, a DME reading shows the pilot the exact position of his aircraft.

distemper: see canine distemper; feline distemper.

disthene (mineral): see kyanite.

distillation, process involving the conversion of a liquid into vapour that is subsequently condensed back to liquid form. It is exemplified at its simplest when steam from a kettle becomes deposited as drops of distilled water on a cold surface. Distillation is used to separate liquids from nonvolatile solids, as in the separation of alcoholic liquors from fermented materials, or in the separation of two or more liquids having different boiling points, as in the separation of gasoline, kerosene, and lubricating oil from crude oil. Other industrial applications include the processing of such chemical products as formaldehyde and phenol and the desalination of seawater. The distillation process appears to have been utilized by the earliest experimentalists. Aristotle (384–322 BC) mentioned that pure water is made by the evaporation of seawater. Pliny the Elder (AD 23–79) described a primitive method of condensation in which the oil obtained by heating rosin is collected on wool placed in the upper part of an apparatus known as a still.

Most methods of distillation used by industry and in laboratory research are variations of simple distillation. This basic operation requires the use of a still or retort in which a liquid is heated, a condenser to cool the vapour, and a receiver to collect the distillate. In heating a mixture of substances, the most volatile or the lowest boiling distills first, and the others subsequently or not at all. This simple apparatus is entirely satisfactory for the purification of a liquid containing nonvolatile material and is reasonably adequate for separating liquids of widely divergent boiling points. For laboratory use, the apparatus is commonly made of glass and connected with

corks, rubber bungs, or ground-glass joints. For industrial applications, larger equipment of metal or ceramic is employed.

A method called fractional distillation, or differential distillation, has been developed for certain applications, such as petroleum refining, because simple distillation is not efficient for separating liquids whose boiling points lie close to one another. In this operation the vapours from a distillation are repeatedly condensed and re-vaporized in an insulated vertical column. Especially important in this connection are the still heads, fractionating columns, and condensers that permit the return of some of the condensed vapour toward the still. The objective is to achieve the closest possible contact between rising vapour and descending liquid so as to allow only the most volatile material to proceed in the form of vapour to the receiver while returning the less volatile material as liquid toward the still. The purification of the more volatile component by contact between such countercurrent streams of vapour and liquid is referred to as rectification, or enrichment.

Multiple-effect distillation, often called multi-stage-flash evaporation, is another elaboration of simple distillation. This operation, used primarily by large commercial desalting plants, does not require heating to convert a liquid into vapour. The liquid is simply passed from a container under high atmospheric pressure to one under lower pressure. The reduced pressure causes the liquid to vaporize rapidly; the resulting vapour is then condensed into distillate.

A variation of the reduced-pressure process uses a vacuum pump to produce a very high vacuum. This method, called vacuum distillation, is sometimes employed when dealing with substances that normally boil at inconveniently high temperatures or that decompose when boiling under atmospheric pressure. Steam distillation is an alternative method of achieving distillation at temperatures lower than the normal boiling point. It is applicable when the material to be distilled is immiscible (incapable of mixing) and chemically non-reactive with water. Examples of such materials include fatty acids and soybean oils. The usual procedure is to pass steam into the liquid in the still to supply heat and cause evaporation of the liquid.

distilled liquor, alcoholic beverage (such as brandy, whiskey, rum, or arrack) that is obtained by distillation from wine or other fermented fruit juice or plant juice or from a starchy material (such as various grains) that has first been brewed. The alcoholic content of distilled liquor is higher than that of beer or wine.

A brief treatment of distilled liquors follows. For full treatment, see *MACROPAEDIA: Beverage Production*.

In general, the raw material used for a distilled liquor is a natural sugar or a starchy substance that may be easily converted into a sugar. Grapes are a principal raw material used for the production of distilled liquor, producing brandy. Peaches, apples, and many other fruits are used according to local availability. The most common vegetables used are sugarcane and sugar beets, which produce rum. Corn is the most widely used grain. Rye, rice, and barley grains are also used. Distilled liquors made from grain are usually called whiskeys.

The distillation process is based on the different boiling points of water (212° F [100° C]) and alcohol (173° F [78.5° C]). The alcohol vapours that arise while the fermented liquid boils are trapped and recondensed to create a liquid of much greater alcoholic strength. The resultant distillate is matured, often for several years, before it is packaged and sold.

Distinguished Service Order, British military decoration awarded to officers who have

performed meritorious or distinguished service in war. The decoration, instituted by Queen Victoria in 1886, entitles recipients to add D.S.O. after their names. Foreign officers associated with British forces can become holders of the award as "honorary members." The badge of the order is a white and gold cross with a red centre bearing a crown surrounded by a laurel wreath.

distortion, in acoustics and electronics, any change in a signal that alters the basic waveform or the relationship between various frequency components; it is usually a degradation of the signal. Straight amplification or attenuation without alteration of the waveform is not usually considered to be distortion. Amplitude distortion refers to unequal amplification or attenuation of the various frequency components of the signal, and phase distortion refers to unequal reproduction of the various phase relationships in the signal. Intermodulation distortion is a result of nonlinearities in the system such that one frequency component tends to modulate another frequency component—e.g., a high audio frequency modulating a low audio frequency. In audio systems, the most noticeable types of distortion are amplitude, frequency, and intermodulation. In video systems, appreciable distortion of any kind may be observed as a degradation of the reproduced image. Noise added to a signal, either purposely or inadvertently, is sometimes referred to as distortion.

distress, in law, process that enables a person to seize and detain from a wrongdoer some chattel, or item of personal property, as a pledge for the redressing of an injury, the performance of a duty, or the satisfaction of a demand. Distress was frequently levied without legal process, but requirements have become more stringent and now often necessitate some type of court action.

Seizure of property was common in ancient societies as a means of obtaining satisfaction for crime, breach of contract, nonpayment of debt, or any other offense or injury. It continues in modern times in nearly all legal systems.

The main causes for which distress is allowed vary from country to country. In general, they include (1) the nonpayment of rent, (2) trespass and damage by cattle or other chattels, (3) nonpayment of taxes and certain fines, and (4) nonpayment for goods and services received.

Initially the right of distress was a mere passive right to detain goods distrained until payment or recompense was made; this right still exists in many places when there has been damage or trespass by cattle. In other cases the power to sell the goods to pay the sum due has been conferred by statute. Certain types of goods are usually exempt from distress: goods in actual use, perishable goods, and the apparel and bedding of a tenant.

Because it affords an opportunity for injustice and discriminates in favour of one particular class of creditors, the distress form of self-help, or seizure of property, has not been favoured in some countries, such as the United States. Where the remedy still remains, it generally has been modified to vest enforcement in a public official and to narrow the right in other ways.

distress signal, a method by which a ship at sea can summon assistance. Distress signals are fixed by custom and by internationally agreed-on rules of the road at sea. The most important are: (1) visual signals, such as a flame, a red flare, an orange smoke signal, or a square flag displayed with a ball below; (2) sound signals, such as a gun or rocket fired at regular intervals, or a continuous sounding of a fog-signal apparatus; and (3) radio signals such as the Morse group SOS, the international code signal NC, or the spoken word

"Mayday" (from French *m'aider*, "help me"), by radiotelephone. Distressed vessels may also actuate alarms of other vessels by a radio signal consisting of a series of 12 four-second dashes or by a radiotelephone signal consisting of two tones alternately transmitted for 30 to 60 seconds.

distribution, also called *DISTRIBUTION OF TERMS*, in syllogistics, the application of a term of a proposition to the entire class that the term denotes. A term is said to be distributed in a given proposition if that proposition implies all other propositions that differ from it only in having, in place of the original term, any other term whose extension is a part of that of the original term—i.e., if, and only if, the term as it is used in that occurrence covers all the members of the class that it denotes.

Thus, in a proposition of the form "No *S* is *P*," both the subject and the predicate are distributed. In the form "Some *S* is *P*," neither *S* nor *P* is distributed. In "Every *S* is *P*," *S* is distributed, but *P* is not. Lastly, in "Some *S* is not *P*," *S* is not distributed, but *P* is. Briefly, only universal propositions distribute the subject term (*S*), and only negative propositions distribute their predicate (*P*). Naturally, singular terms (including proper names used as singular terms) are always distributed, for they refer only to one object and cannot refer to fewer.

The importance of distribution lies in its being a principle of formal inference that no term may be distributed in the conclusion unless it was distributed in the premises.

distribution function, mathematical expression that describes the probability that a system will take on a specific value or set of values. For example, the probability (*dP*) that a molecule of gas will be found with velocity components *u*, *v*, and *w* in the *x*, *y*, and *z* directions, respectively, is given by the product of the distribution function and the infinitesimal volume *du dv dw*; i.e., $dP = f(u, v, w) du dv dw$, in which *f*(*u*, *v*, *w*) is the distribution function describing the velocity of the molecule and *dP* is the probability of finding the *x* component of velocity between *u* and *u + du*, the *y* component between *v* and *v + dv*, etc. (see Maxwell-Boltzmann distribution law). A complete description of a system may involve other variables as well, such as position and orientation. Distribution functions may take into account any or all such variables.

distribution theory, in economics, the systematic attempt to account for the sharing of the national income among the owners of the factors of production—land, labour, and capital. Traditionally, economists have studied how the costs of these factors and the size of their returns—rent, wages, and profit—are fixed.

A brief treatment of distribution theory follows. For full treatment, see *MACROPAEDIA: Economic Theory*.

Distribution theory may be applied to the question of whether national income is distributed among persons or among the factors of production (the problems of personal distribution and distributive shares), but it has proved most fruitful on the question of how the prices of the factors are determined (the problem of functional distribution). The classical economists of the 18th and 19th centuries applied the principles of the market to the determination of the rewards of the factors. Supply was thought to be the most important element, and the influence of demand was rated as fairly insignificant. The subsistence theory of wages, derived in large part from the teachings of Thomas Malthus, held that wages would not diverge significantly from a

"natural" level that was just enough to enable the wage earner to live at a subsistence level. Higher levels of earnings would increase the supply of labour through larger families and depress the wages back to subsistence level. Conversely, if the wage rate fell below the subsistence level, the number of workers would decrease and the ensuing shortage would push wages back up.

The classical theory of rent (from David Ricardo) held that rent—the return to landowners—was determined by the cost of production of the least favourable land worthwhile to cultivate. Thus, land of better quality had a surplus rent over and above the cost of production. For the economy as a whole the total amount of the rent surplus received from land represented the landowner's share of national income. The remainder of the income produced in the economy was available for distribution among the other two economic groups, labourers and capitalists. It was the view of a number of classical economists that in the long run these two groups would not reap the benefits of economic growth, while the position of the landlord class would be substantially improved.

As the rapid economic development of the 19th century produced conditions quite different from those predicted by the classical economists, new approaches were required to account for the prices of factors of production. Marginal-productivity theories were developed independently by a number of economists. According to the marginal-productivity theory, the price of a factor is not governed by simply its productivity but its productivity at the margin, that is, the value of the extra output made possible by the addition of a unit of the factor. The earnings rate of any factor of production tends to equal the value of the marginal product of the factor. The theory assumes that the law of diminishing returns applies to marginal productivity of a factor and that substitution of one factor for another at the margin is similarly affected by diminishing returns. The effect of the diminishing return is to reduce the price as the marginal productivity declines. Other key assumptions of the theory are that to a large degree the economy is static, that it is possible to measure the productivity of each factor of production, and that nearly perfect competition prevails in the marketplace. The ratio in which the factors are combined is determined by employers, guided by the principles of substitution and diminishing marginal productivity and varying their demand for any one factor until its marginal productivity is equal to its price or earnings.

This neoclassical theory is particularly successful in explaining the phenomenon, observed in industrializing nations, that labour commands an increasing share of national income and capital a decreasing one. The removal of the assumptions of stasis and perfect competition introduces an element of indeterminacy, because, in practice, wage rates are influenced by collective bargaining between trade unions and employers, by various forms of arbitration, or by minimum-wage levels set by government. Similarly, under imperfect and dynamic competition the earnings of capital are determined by a host of other factors, such as technological change, monopolistic trends, and government influence over the economy.

distributive law, in mathematics, the law relating to number operations stated symbolically, $a(b + c + d) = ab + ac + ad$; that is, the monomial factor a is distributed, or separately applied, to each term of the polynomial factor $b + c + d$, resulting in the product $ab + ac + ad$. Hence, the result of first adding several numbers and then multiplying the sum

by some number is the same as first multiplying each separately by the number and then adding the products. See also associative law; commutative law.

District of Columbia, federal district, eastern United States, on the Potomac River, coextensive with the city of Washington, D.C. (*q.v.*).

disturbing the peace, also called BREACH OF THE PEACE, any of three distinct types of legal offense. In its broadest sense, the term is synonymous with crime itself and means an indictable offense. In another and more common sense, however, the phrase includes only those crimes that are punishable primarily because of their disrupting effect upon the peace and security of the community. Among these offenses are affray, unlawful assembly, riot, forcible entry and detainer, disturbance of public assemblies, keeping a disorderly house, and malicious mischief. In its third and narrowest meaning, the phrase is confined to willful conduct that does not fall within the definition of any other specific crime but that unreasonably disrupts the public tranquillity or has a strong tendency to cause a disturbance. In common law, and under many statutes, such a disturbance or breach of peace is punishable as a misdemeanor.

Ditch, Battle of the (AD 627), Arabic AL-KHANDAQ (The Ditch), an early Muslim victory that ultimately forced the Meccans to recognize the political and religious strength of the Muslim community in Medina.

A Meccan army of 3,000 men had defeated the undisciplined Muslim forces at Uhud near Medina in 625, wounding Muhammad himself. In March 627, when they had persuaded a number of Bedouin tribes to join their cause, the Meccans brought a force of 10,000 men against Medina again. Muhammad then resorted to tactics unfamiliar to the Arabs, who were accustomed to brief, isolated raids. Rather than sally out to meet the enemy in the usual way—the mistake made at Uhud—he had a ditch dug around Medina, according to tradition, at the suggestion of a Persian convert, Salmān. The Meccan horsemen were disconcerted and soon bored, and the coalition of Bedouin tribes started breaking up. After an unsuccessful siege, the Meccans dispersed. With the Muslim and Meccan forces now more evenly matched and the Meccans tiring of a war that was damaging their trade, Muhammad used his victory to negotiate greater concessions for the Muslims in a treaty at al-Hudaybiyah (628).

ditcher: see trenching machine.

Dithmar (historian): see Thietmar.

Dithmarschen, Danish DITMARSKEN, area on the west coast of the Jutland peninsula between the Eider and Elbe rivers, now included in the Land (state) of Schleswig-Holstein, Germany, but down to 1866 a semi-independent territory under the king of Denmark. First mentioned in the 9th century, Dithmarschen was then one of the three Saxon districts north of the Elbe. In 1144 the ruling count was killed in a popular rising, and, after a dispute between the Duke of Saxony and the Archbishop of Bremen, Dithmarschen passed to the latter.

In 1434 the federated parishes created a central judiciary that developed into an administration by 48 regents, and in 1447 the customary laws were codified. In 1473 the Holy Roman emperor Frederick III enfeoffed Christian I of Denmark with Dithmarschen, but the Danish kings' attempts to make good this grant ended in humiliating defeat at Hemmingstedt (February 1500). In 1580 the province was divided into royal South Dithmarschen and ducal (Gottorp) North Dithmarschen; these districts remained even when in 1773 the whole territory fell to the king

of Denmark. In 1867 Dithmarschen, together with Schleswig and Holstein, became Prussian.

dithyramb, in Greece in the 7th century BC, an improvised song in honour of the wine god Dionysus, sung by banqueters under the leadership of a man "wit-stricken by the thunderbolt of wine" (Archilochus). It was contrasted with the more sober paean, sung in honour of Apollo. The dithyramb began to achieve literary distinction about 600 BC, when the poet Arion composed works of this type, gave them names, and formally presented them at the Great Dionysia competitions at Corinth. These presentations consisted of a dithyrambic song accompanied by circular dances performed around the altar of Dionysus by choruses composed of 50 men and boys; the whole proceeding was accompanied by reed flutes and was led by the speaker of a prologue.

By the end of the 6th century BC, the dithyramb was a fully recognized literary genre. Its most famous composer was Lasus of Hermione (b. c. 548), who is said to have been one of Pindar's teachers. The great age of the dithyramb was also the great age of Greek choral lyric poetry in general; Simonides, Pindar, and Bacchylides all composed them. Of Simonides' and Pindar's dithyrambs, little is known; but two of Bacchylides' are complete, and there are considerable fragments of several others. Bacchylides' Ode 18 is unusual in that it contains a dialogue between a chorus and a soloist. This attempt to increase the dramatic interest of the narrative may explain why the classical dithyramb gave way before the more vivid methods of tragedy.

From about 450 BC onward, dithyrambic poets employed ever-more-startling devices of language and music, until for ancient literary critics "dithyrambic" acquired the connotations of "turgid" and "bombastic." True dithyrambs are rare in modern poetry, although John Dryden's "Alexander's Feast" (1697) may be said to bear a coincidental resemblance to the form.

dittany, any of several plants: European dittany (see gasplant), Maryland dittany (*Cunila organoides*), and Crete dittany (*Origanum dictamnus*). The last two mentioned are of the mint family (Lamiaceae), order Lamiales. *C. organoides*, common in dry woodlands and prairies, was once used as a remedy for fever and snakebite. It attains heights of 30 cm (1 foot) and has mint-scented leaves and clusters of rose-purple to white, tubular flowers. It and 14 other species of *Cunila* are native in North and South America.

Common dittany (*Cunila organoides*)

Franklin Photo Agency

Origanum dictamnus, related to marjoram, has white, woolly, weak stems, thick leaves, and pinkish flower clusters. It is native in Greece and is much-used in cookery.

Ditters von Dittersdorf, Carl, original name (until 1773) CARL DITTERS (b. Nov. 2, 1739, Vienna, Austria—d. Oct. 24, 1799, Rothlhotta Castle, Neuhoft, Bohemia [now Nové Dvory, Czech Republic]), violinist and composer of instrumental music and of light operas that established the form of the Singspiel (a comic 18th-century opera in the German language).

Ditters, engraving by Karl Traugott Riedel
By courtesy of the Österreichische Nationalbibliothek, Vienna

A brilliant child violinist, Ditters played regularly at the age of 12 in the orchestra of Prince von Sachsen-Hildburghausen and later in the orchestra of the Vienna opera. He became friendly with the composer Christoph Gluck and accompanied him in 1761 to Bologna, Italy. There Ditters gained considerable celebrity with his violin playing. In 1765 he became director of the orchestra of the bishop of Grosswardein and wrote for it his first opera, *Amore in musica* ("Love in Music"). His first oratorio, *Isacco* ("Isaac"), was also written during this time.

By 1770 Ditters was in the service of Count Schaffgotsch, prince-bishop of Breslau, at Johannsberg, Silesia, Prussia. There he composed 11 comic operas, among them *Il viaggiatore americano* (1770; "The American Traveler"), and an oratorio, *Davidde penitente* (1770; "Penitent David"). In 1773 he was ennobled under the name Ditters von Dittersdorf. In about 1779 he formed a close friendship with Joseph Haydn, and from 1783 he played in string quartets in Vienna with W.A. Mozart. From this period onward his output was enormous. He produced the oratorio *Giobbe* (1786) and several operas, three of which, *Doktor und Apotheker* (1786; "Doctor and Apothecary"), *Hieronimus Knicker* (1789), and *Das rote Käppchen* (1790; "The Little Red Hood"), had great success. *Doktor und Apotheker*, in particular, became one of the classic examples of the German Singspiel. He also wrote a large quantity of instrumental music. In 1795, following the bishop's death, Ditters was dismissed with a small pension. Poor and broken in health, he accepted a post with Baron Ignaz von Stillfried at Rothlhotta Castle in Bohemia. On his deathbed he dictated his autobiography, which is of great interest to students of 18th-century music.

Ditters was one of the earliest composers of the Viennese Classical school. His symphonies are often of great interest. His violin concerti are worthy of study, and his concerti for harp, for flute, for harpsichord, for double bass, and for other instruments are performed and recorded. As an opera composer Ditters is chiefly remembered for his lighthearted and sometimes sentimental Singspiels.

Diu, formerly DIO, town, Damān and Diu union territory, western India. It is situated on an island in the Gulf of Khambhāt (Cambay)

of the Arabian Sea, off the southern tip of the Kāthiāwār Peninsula in southeastern Gujarāt state. Diu Island is about 7 miles (11 km) long and 2 miles (3 km) wide. It is known for its magnificent Cathedral of Sē Matriz and its idyllic beauty. Diu fell to the Portuguese in 1535 and remained a Portuguese colony until 1961. Bitter fighting then broke out at Diu before India was able to assert control of the island. Diu was part of Goa, Damān, and Diu union territory until 1987, when Goa became a separate state of India. Bajra (pearl millet) and coconuts are the major crops; industries include fishing, tapping of the toddy palm for its juice, and salt processing. The island has an airport. Pop. (1991 prelim.) town, 20,643.

Diula (people): see Dyula.

diuretic, any drug that increases the flow of urine. Diuretics promote the removal from the body of excess water, salts, poisons, and accumulated metabolic products, such as urea. They serve to rid the body of excess fluid (edema) that accumulates in the tissues owing to various disease states.

There are many types of diuretics, but most act by decreasing the amount of fluid that is reabsorbed by the tubules of the kidneys, whence the fluid passes back into the blood. The most widely used diuretics, the benzothiadiazides (e.g., chlorothiazide), interfere with the reabsorption of salt and water by the kidney tubules. Instead of being reabsorbed, the salt and water are ultimately excreted, thus increasing the flow of urine. After they were synthesized in the late 1950s, the benzothiadiazides replaced most other existing diuretics. They are more convenient than some other diuretics in that they can be taken orally in the form of pills. These drugs are also used to reduce high blood pressure (hypertension).

Mercurial diuretics (e.g., calomel) work as do benzothiadiazides but are less easy to use. Another class of diuretics are substances that cannot be reabsorbed by the kidney tubules and thus limit the reabsorption of water by the tubules. These include mannitol, sucrose, and urea. Other diuretics (e.g., acetazolamide) work by blocking the reabsorption of sodium bicarbonate by the tubules, thus increasing urine formation. These and still other types are used infrequently in conjunction with the mercurial diuretics.

diurnal motion, apparent daily motion of the heavens from east to west in which celestial objects seem to rise and set, a phenomenon that results from the Earth's rotation from west to east. The axis of this apparent motion coincides with the Earth's axis of rotation. The intersection of the plane of the Earth's Equator with the celestial sphere defines the celestial equator. The apparent daily paths of celestial objects are circles parallel to the celestial equator and are termed diurnal circles.

Diushambe (Tajikistan): see Dushanbe.

Divākaraṇḍita, original name DIVĀKARA (b. 1040, Cambodia—d. c. 1120), Hindu of the Brahman (priestly) caste who rose through religious and administrative ranks to serve four Cambodian kings—Harshavarman II, Jayavarman VI, Dharanindravarman I, and the great Suryavarman II—and who was the most trusted adviser to three of them.

The highly opportunistic Divākara was able not only to survive the successive usurpations of monarchies but also to ingratiate himself with each new sovereign. Divākaraṇḍita played a singular role in Cambodian history, for it was at his urging that Suryavarman II began construction of the temple of Angkor Wat, one of the world's largest religious edifices and certainly one of the greatest achievements of ancient Khmer, or Cambodian, civilization. One of the monuments of Angkor Wat commemorates this powerful Brahman.

Divāli (Hindu festival): see Dīwālī.

divan, also spelled DIWAN, or DEWAN, Arabic DĪWĀN, in Islāmic societies, a "register," or logbook, and later a "finance department," "government bureau," or "administration." The first divan appeared under the caliph 'Umar I (634–644) as a pensions list, recording free Arab warriors entitled to a share of the spoils of war. Out of rents and property taxes exacted from conquered farmers and landowners, hereditary pensions were assigned to warriors entered in the divan. Later the term came to signify a financial institution, and, by the time of the caliphate of Mu'āwiyah (661–680), it meant a government bureau, e.g., the chancellery or the postal service. Iranians used the term divan until about the 19th century to mean the central government in general, while in Mughal India, from the time of Akbar (1556–1605), the term was chiefly associated with government finance, the chief finance minister being the divan, with provincial *dawāwīn* under him. In the Ottoman Empire the divan became the imperial chancery headed by the grand vizier, though a consultative assembly of senior officials summoned by Selim I in 1515 was also called a divan. The term was early extended to mean the audience chamber of important government officers, whose offices, furnished with mattresses and cushions along the walls, account for the extension of the meaning of divan to sofa. In modern Turkey a divan is an administrative unit in rural areas.

The English East India Company, during its period of administration in India, called its revenue administration "dewanee."

diver (bird): see loon.

divergence (meteorology): see convergence and divergence.

diverticulum, plural DIVERTICULA, in physiology, any small pouch or sac that forms in the wall of a major organ of the human body. Diverticula form most commonly in the esophagus, small intestine, and large intestine and are most often a problem in the latter organ. Middle-aged and older people are particularly susceptible to the condition because of the inevitable weakening of the muscle walls of the colon with advancing age.

Fecal matter may be pushed into the pouches that form in the colon and may cause them to bulge out from the colon wall. Such a condition is called diverticulosis. This condition has no symptoms, but the feces-filled sacs may become inflamed, a more serious condition called diverticulitis. Its symptoms are pain and cramps in the lower left side of the abdomen, chills, and sometimes fever. At this stage an accurate diagnosis becomes necessary, and the presence of pouches can be determined on an X-ray film taken after the patient has been given a barium enema. The treatment for a mild case of diverticulitis consists of bed rest, antibiotics, an enema, and a bland diet. A severe case can cause the perforation, rupture, ulceration, or hemorrhaging of the colon wall at the spot of the bulge. In cases of rupture, the surgical operation known as a colostomy may be necessary.

divertimento (Italian: "diversion," or "amusement"), plural DIVERTIMENTI, 18th-century musical genre of a light and entertaining nature usually consisting of several movements for strings, winds, or both. The movements included sonata forms, variation forms, dances, and rondos. One of Joseph Haydn's numerous divertimenti is a sextet written for a double string trio, to be played by two groups simultaneously in different rooms. The divertimenti of W.A. Mozart generally resemble his works entitled cassation and serenade; an exception is the *String Divertimento* K 563, which ranks among the greatest chamber works of all time.

The divertimento was one of the sources from which the string quartet developed. Its style was to some extent maintained by Beethoven in the *Septet*, Opus 20, and Schubert in the *Octet*, Opus 166, both for winds and strings.

dividend, an individual share of earnings distributed among stockholders of a corporation or company in proportion to their holdings and as determined by the class of their holdings. Dividends are usually payable in cash, although sometimes distributions are made in the form of additional shares of stock. The preferred stockholders are entitled to a preferential dividend, usually at a fixed rate, and the common stockholders get a portion of what remains after payment of the dividends on preferred stock.

When a corporation declares a dividend, it indicates that stockholders of record as of a specific date will receive the dividend. If the stock is purchased between the date of record and the date the dividend is to be paid, the buyer does not receive the recently declared dividend, and the stock is said to sell ex dividend, or "without dividend." When a stock sells ex dividend, its price is usually reduced by the amount of the dividend.

divider, instrument for measuring, transferring, or marking off distances, consisting of two straight adjustable legs hinged together and ending in sharp points. It is used principally in drafting for the accurate transfer of dimensions from a measuring scale and in machine shops for scribing lines on surfaces, usu-

Divider

ally machined, with dimensions taken from a ruler. A compass is essentially a divider in which one of the points has been replaced by a pencil or other marking device. The compass is useful for scribing circles or arcs of circles; it usually includes a scale to indicate the radius of the circle being scribed.

divination, the practice of foretelling the future by various natural, psychological, and other techniques. Found in all civilizations—both ancient and modern, primitive and sophisticated—and in all areas, it is known in the Western world primarily in the form of horoscopic astrology (see astrology). No scientific evidence has been produced showing that divination can indeed foretell the future.

A brief treatment of divination follows. For full treatment, see MACROPAEDIA: Occultism.

Divinatory methods may be classified as inductive, interpretive, or intuitive. Inductive and interpretive divination are performed by inference from external facts. Manipulated accident is the essential dramatic element of interpretive divination. In a classic example, a diviner randomly tosses a bunch of selected objects on the ground and foretells the future by interpreting the final alignment of the objects where they fell. This approach has been used in a great variety of cultures. The casting of lots, for instance, was common in classical antiquity and survives in the throwing of dice. The use of lots and number lore directs consultation of the *I Ching* in Chinese tradition.

In haruspicy (the inspection of entrails), in scapulimancy (divination by the scapula, or shoulder blade), and in divination by footprints in ashes, the diviner foretells the future by interpreting the visual appearance or condition of a particular object or objects. In the case of augury and omens, the behaviour and cries of birds, encounters with ominous animals, and so on are interpreted. Astrology, based upon observation of the heavenly bodies, is an inductive divining method of great antiquity. Other phenomena commonly subject to such interpretation include dreams, weather, and sequences of cards (e.g., Tarot cards).

Intuitive divination depends for its results on sensory or motor automatisms or mental impressions. The prototype of the intuitive diviner is the shaman who employs trance states—either spontaneous, self-induced, or drug-induced—to achieve contact with superior, nonhuman forces and thereby gain insight into the future.

Among sensory automatisms, crystal gazing is used to induce visions of future events. The Ouija board is a popular approach to divination using motor automatism.

Divine, Father, also called J. DEVINE, by-name of GEORGE BAKER (b. 1877?, Hutchinson's Island, near Savannah, Ga., U.S.—d. Sept. 10, 1965, Philadelphia), American religious leader who in 1919 founded the Peace Mission movement.

Baker began preaching in Baltimore, where he became known as "The Messenger" by his followers. After briefly returning to Georgia, he moved to New York City in 1915. He adopted the name Major J. Devine (later Divine) shortly thereafter and in 1919 established his first "heaven," or communal dwelling, in Sayville, Long Island, N.Y. His predominantly black following expanded rapidly in the 1930s and '40s, and more "heavens" were provided in distant cities; by the 1960s the organization owned more than \$10,000,000 in property. Father Divine was regarded by his followers as God, and he did not permit them to smoke, drink liquor, or use cosmetics. The movement declined after his death.

Divine Comedy, The, Italian LA DIVINA COMMEDIA, original name COMMEDIA, long narrative poem written c. 1310–14 by Dante Alighieri (q.v.). It is usually held to be one of the world's great works of literature. Divided into three major sections—*Inferno*, *Purgatorio*, and *Paradiso*—the narrative traces the journey of Dante from darkness and error to the revelation of the divine light, culminating in the Beatific Vision of God. Dante is guided by the Roman poet Virgil, who represents the epitome of human knowledge, from the dark wood through the descending circles of the pit of Hell (*Inferno*). Passing Lucifer at the pit's bottom, at the dead-centre of the world, Dante and Virgil emerge on the beach of the island mountain of Purgatory. At the summit of Purgatory, where repentant sinners are purged of their sins, Virgil departs, having led Dante as far as human knowledge is able, to the threshold of Paradise. There Dante is met by Beatrice (q.v.), embodying the knowledge of divine mysteries bestowed by Grace, who leads him through the successive ascending levels of heaven to the Empyrean, where he is allowed to glimpse, for a moment, the glory of God.

An early translation of *La divina commedia* into English was by Henry Boyd (1802). There are several later translations, the best-known among which are those by Dorothy L. Sayers and B. Reynolds (1949–62), W.F. Ennis (1965), and John Ciardi (1977).

Divine Faith (Mughal sect): see Dīn-i Ilāhī.

divine office, also called CANONICAL HOURS, LITURGY OF THE HOURS, or LITURGICAL HOURS, in various Christian churches, the

public service of praise and worship consisting of psalms, hymns, prayers, readings from the Fathers of the early church, and other writings. Recurring at various times during the day and night, it is intended to sanctify the life of the Christian community.

The history of the office, and of its various forms, is difficult to trace, as a result of its antiquity and the revisions created during the numerous attempts to reform it. The practice of public morning and evening prayer is very ancient, and early writings attest to the tradition of prayer at the third, sixth, and ninth hours of the day (9:00 AM, 12:00 M, and 3:00 PM). The practice of midnight prayer, especially before a great feast, also was common. Two institutions greatly responsible for the evolution of the forms of the office, in both Eastern and Western Christianity, were the monasteries and the choirs associated first with the churches known as basilicas and later with cathedrals.

In the Roman Catholic Church, there are seven canonical hours. Matins, the lengthiest, originally said at a night hour, is now appropriately said at any hour of the day. Lauds and Vespers are the solemn morning and evening prayers of the church. Terce, Sext, and None correspond to the mid-morning, noon, and mid-afternoon hours. Compline, a night prayer, is of monastic origin, as was Prime, recited in the early morning before being suppressed in 1964. The office has for centuries been primarily the responsibility of monks, who sang it in choir, and priests, who often recited it privately. The second Vatican Council encouraged the celebration of Lauds and Vespers in parish churches and initiated significant changes in structure and texts to facilitate the recitation of the office by those involved in active pursuits.

In the liturgical tradition of the Eastern Orthodox Church, the day is considered to begin at sunset with Vespers. Compline is read after the evening meal. The midnight office, which has no exact equivalent in the West, is in practice normally recited before Matins, which in principle should conclude with sunrise. The lesser hours are celebrated at the first, third, sixth, and ninth hours. There is no separate office of Lauds. The daily cycle is celebrated in full only in large monasteries. Matins and Vespers, however, are celebrated in many parish churches. Because it is viewed as a corporate activity, the private recitation of the office has not been a custom in the East.

The Anglican Church has a morning prayer containing elements of the Matins, Lauds, and Prime of the medieval church and has an evening prayer with elements from Vespers and Compline. Both services have the same structure. Lutheran churches have forms for Matins and Vespers services for congregational celebration mainly on Sundays. Although encouraged by Martin Luther, the practice has not been consistently observed. There has been, however, a revival of interest in recent years. See also breviary.

divine right of kings, doctrine in defense of monarchical absolutism, which asserted that kings derived their authority from God and could not therefore be held accountable for their actions by any earthly authority such as a parliament. In its origins in Europe the divine right theory may be traced to the medieval conception of God's award of temporal power to the political ruler, paralleling the award of spiritual power to the church. By the 16th and 17th centuries, however, the new national monarchs were asserting their authority in matters of both church and state. King James I of England (reigned 1603–25) was the foremost exponent of the doctrine of the divine right of kings, but the doctrine virtually disappeared from English politics after the Revolution of 1688. In the late 17th and

the 18th centuries, kings such as Louis XIV of France continued to profit from the divine-right theory, even though many of them no longer had any truly religious belief in it. The American Revolution, the French Revolution, and the Napoleonic Era deprived the doctrine of most of its remaining credibility.

One of the principal French theorists of divine right, the bishop Jacques-Bénigne Bossuet (1627–1704), asserted that the king's person and authority were sacred; that his power was modeled on that of a father's; that his power was absolute, deriving from God; and that he was governed by reason (that is, custom and precedent). The English Royalist squire Sir Robert Filmer, in his *Patriarcha* (1648), likewise held that the state was a family and that the king was a father, but he went on, in an interpretation of Scripture, to pronounce that Adam was the first king and that Charles I ruled England as Adam's eldest heir. The philosopher John Locke wrote the antiabsolutist *First Treatise of Civil Government* (1689) to refute such arguments.

Divine Word Missionary, member of the Society of the Divine Word, or *Societas Verbi Divini* (SVD), a Roman Catholic organization composed of priests and brothers, founded in 1875 at Steyl, Neth., by Arnold Janssen to work in foreign missions. Its members are engaged in all phases of missionary activity, from teaching in universities, colleges, and secondary schools to working among local populations. In the early 21st century Divine Word Missionaries were active in more than 60 countries worldwide. The training of a native clergy has been a major work of the society in all its missions. Divine Word Missionaries have traditionally been active in publishing and disseminating Catholic literature. Some members, notably Wilhelm Schmidt, a German anthropologist, have made valuable contributions in the fields of anthropology and ethnology.

diving, sport of plunging into water, usually head foremost, performed with the addition of gymnastic and acrobatic stunts. In its more elaborate, acrobatic form, diving originated in Europe early in the 19th century as a diversion of gymnasts and in the late 19th century as a competitive sport. It became a part of the swimming program of the Olympic Games in 1904 and developed rapidly through the first half of the 20th century. For world champions, see *Sporting Record: Swimming*. See also *Olympic Games*.

In competition, dives are performed from a platform 5 or 10 metres (16.4 or 32.8 feet) above the water or from an elastic springboard 1 or 3 metres high. In Olympic contests only the 10-metre platform and 3-metre springboard are used. Dives performed in competition are listed, together with a rating of their degree of difficulty, in a table published by the Fédération Internationale de Natation Amateur (FINA; International Amateur Swimming Federation). Contestants are required to do certain of the listed dives, as well as several of their own choice. At least 3 but not more than 10 judges score each dive, with attention paid to take-off, bearing of the body in the air, execution of the prescribed movements, and entry into the water. The scores for each dive are totaled and multiplied by the degree of difficulty. The diver with the highest total score at the end of the contest is the winner. In the springboard competition, men make 11 dives: 5 voluntary and 6 optional. Women make the same 5 voluntary dives, but only 5 optional dives. Platform events require 10 dives from men and 8 from women.

Competitive dives are divided into five groups. The first includes the forward dives, in which the person faces the water, dives out from the edge of the board or platform, and

Vladimir Timoshinin (Russia) in a pike position during the platform event at the 1998 Goodwill Games in New York

Jamie Squire/Getty Images

rotates forward one-half or more turns before entering the water. The second comprises the backward dives, in which the diver stands at the edge, facing away from the water, then springs and rotates backward. The third is the reverse group, in which the diver takes off in the forward position but then reverses his spin toward the board. In the fourth group, the inward dives, the diver stands on the edge of the platform and springs backward but rotates forward, again toward the board. The fifth classification is that of the twisting dives, in which the diver rotates the body on its long axis while performing one of the other four types of dives—as in a forward somersault with two twists. The five voluntary dives comprise one selected from each group. A sixth group—arm-stand dives—are done from fixed platforms only.

The majority of dives may be executed in three distinct positions: straight, pike, or tuck. In the straight position, the body is held extended, with no flexion at the hips or knees. In the pike position, there is a bend at the hips but no knee flexion. In the tuck position, both hips and knees are flexed and the body resembles a ball. The most complicated dives may be done in free (any) position, a loose but graceful combination of the others.

Synchronized diving, introduced to the Olympic Games in 2002 with platform and springboard events, features teams of two divers who perform the same dive simultaneously. Teams are judged on the quality of their individual dives and on their synchronicity.

diving, underwater: see underwater diving.

diving beetle: see predaceous diving beetle.

diving bell, small diving apparatus that is used to transport divers between the seafloor or lower depths and the surface. Early bells consisted of a container open only at the bottom, usually provided with a source of compressed air. Though the diving bell in rudimentary form is mentioned by Aristotle, the device was not fully practicable until the end of the 18th century, when the British engineer John Smeaton fitted an air pump to the bell. Regardless of the depth to which a diving bell is lowered, in principle at least, fresh air fills the available vital space. Its pressure is automatically regulated by the pump and by the water pressure; surplus air escapes through the edges of the container. As the bell descends, the water level tends to rise inside the bell. As it surfaces, the decreasing water pressure lowers the level inside the bell. Thus, the pressure inside the bell remains the same as that out-

side. Some bells, however, are kept at working-depth pressure and are used to commute to and from an outfitted surface decompression chamber and the work site, thus eliminating the need for decompression between dives on a mission. Modern bells may accommodate up to four divers and have been used at depths of more than 1,000 feet (300 metres).

diving duck, any duck that obtains its food by diving to the bottom in deep water rather than by dabbling in shallows (see dabbling duck). On the basis of kinship and to the degree that it likes a marine environment, a diving duck may be popularly called either a bay duck or a sea duck.

Bay ducks of the tribe Aythyini, family Anatidae (*q.v.*; order Anseriformes), include canvasback, redhead, scaup, and allied species (see pochard). They are found most frequently in estuaries and tidal lagoons.

Sea ducks are any of the approximately 20 species of the tribes Mergini and Somateriini. The term is fairly apt, although some birds frequent inland waters as well as sea-coasts. Ducks of the tribe Mergini include the bufflehead (*Bucephala*, or *Glacionetta*, *albeola*), closely related to the goldeneye (*B.*, or *G.*, *clangula*); the mergansers; the old-squaw (*Clangula hyemalis*); and scoters (*Melanitta*, or *Oidemia*, species). The tribe Somateriini includes the eiders. See also eider; merganser.

diving petrel, any of five species of small sub-Antarctic seabirds that constitute the family Pterodromidae (order Procellariiformes). Their nearest relatives are the storm petrels, shearwaters, and albatrosses. Diving petrels differ from these long-winged forms and instead resemble the smaller auks of the Northern Hemisphere, a classic example of convergent evolution. Like the auks, black-and-white diving petrels are short-winged and heavy-bodied and use their wings for propulsion underwater. The smallest and most widespread is the common diving petrel (*Pelecanoides urinatrix*), about 16 cm (6.5 inches) long; the largest is the Peruvian diving petrel (*P. garnotii*), about 25 cm long, restricted to the west coast of South America.

diving suit, watertight costume for underwater use, connected to the surface or to a diving bell by a tube that provides the wearer with air. The suit, invented early in the 19th century, consists of a watertight covering, weighted boots, and a metal helmet with transparent portholes and provision for air. Suits of articulated armour that do not require decompression have been developed. Diving suits have been supplanted in some applications by scuba-diving equipment.

Diver being assisted into a diving suit
NAUTIEK/GB Diving

Divini, Eustachio (b. Oct. 4, 1610, San Severino delle Marche, near Ancona, Papal States [now in Italy]—d. 1685, Rome), Italian scientist, one of the first to develop the technology for producing scientific optical instruments.

After some scientific training under Benedetto Castelli, a disciple of Galileo, Divini established himself in Rome in 1646 as a maker of clocks and lenses. He constructed a number of compound microscopes and long-focus telescopes, the latter consisting of wooden tubes with four lenses, with a focal length of more than 15 m (50 feet).

In 1649 Divini published a copper engraving of a map of the Moon, based on his own observations made with his invention. He also made a number of astronomical observations, including some of the rings of Saturn and the spots and satellites of Jupiter. Many of his microscopes and telescopes have survived in museums in Florence, Rome, Padua, and elsewhere.

divining rod, instrument used in dowsing (*q.v.*).

Divino, El (poet): *see* Herrera, Fernando de.

Divinópolis, city, south-central Minas Gerais estado ("state"), Brazil. It is situated in highlands at 2,205 feet (672 m) above sea level, near the Pará River. It was made the seat of a municipality in 1911 and gained city status in 1915. The growing of cassava, corn (maize), rice, coffee, *feijão* (beans), and sugarcane and the raising of livestock are economically important in the surrounding area. The city is one of the most important industrial centres in Minas Gerais, with metallurgical plants, textile mills, tanneries, and dairy factories. Roads and a railway link Divinópolis to Belo Horizonte, the state capital, 97 miles (156 km) east. Pop. (2003 est.) 187,700.

division, in modern military organizations, the smallest formation that comprises a balanced team of all the arms and services needed for the independent conduct of operations. It usually numbers between 12,000 and 20,000 men and is commanded by a major general. In naval usage a division is a group of ships, usually four, forming part of a squadron or task force. It also denotes units into which a ship's company is divided for administrative purposes. The term air division denotes a command within an air force, containing two or more wings organized to perform an operational mission such as bombardment, fighter interception, reconnaissance, or airlift.

The military strength of an army for the conduct of war may be roughly measured by the number and quality of the divisions it can bring to bear against an enemy. Divisions, together with additional supporting combat and service troops, are formed into corps and field armies for the conduct of military campaigns.

To meet specialized requirements in warfare, divisions have evolved into several types, falling within two general classifications: infantry and armoured. Infantry divisions, known as rifle divisions in the Russian army, are organized and equipped for combat under all conditions of terrain and weather; they comprise the principal portion of the fighting forces of an army. An infantry division consists chiefly of foot soldiers equipped with light weapons but also includes supporting artillery, armour, and engineer units and has its own communication, supply, maintenance, and evacuation services. Divisions of this general type, when modified by the introduction of light equipment and given special training, may perform specialized roles. Examples are airborne (parachute) divisions and mountain (Alpine) divisions. Some armies also have formed motorized (in American usage, mechanized) divisions by adding truck transport

and light armoured vehicles sufficient to mount all the troops of an infantry division. The armoured, or (except in American usage) mechanized, division also contains elements of all arms and services but is comparatively much stronger in tank forces than the infantry division. When faced by defenses in depth, the tanks, infantry, engineers, artillery, and antitank weapons of a division work as a coordinated team.

division of labour: *see* labour, division of.

Divisionism, painting technique that formed the technical basis for Neo-Impressionism (*q.v.*).

Divo, town, south-central Côte d'Ivoire (Ivory Coast). It is the chief collecting centre among the Dida people for the bananas, pineapples, coffee, cocoa, timber, and rubber grown in the surrounding area for export. The town is the site of a government coffee and cocoa research institute and Christian churches and has grown significantly since the 1970s through migration. Pop. (2001 est.) 140,300.

divorce, the act by which a valid marriage is dissolved, usually freeing the parties to remarry. In regions in which ancient religious authority still predominates, divorce may be difficult and rare, especially when, as among Roman Catholics and Hindus, the religious tradition views marriage as indissoluble. (For Jewish tradition of divorce, *see* *get*.) Custom may make divorce a simple matter in some societies. Among some Pueblo Indian tribes a woman could divorce her husband by leaving his moccasins on the doorstep. The principles of individual determination and mutual consent are making divorce increasingly acceptable in the industrialized world.

Among premodern societies, the rate of marital stability is difficult to measure because of the varying definitions of marriage and divorce. It seems to be broadly true that wherever divorce is a legal impossibility the wedding is a well-defined event. The contrary principle does not hold true: elaborate marriage ceremonial is quite compatible with high divorce rates. Many anthropologists agree that divorce is generally more permissible in matrilineal societies than in patrilineal ones, in which the procreative and sexual rights of the bride are often symbolically transferred to the husband with the payment of bride-price. *See also* family.

Divriği, town, central Turkey. It is situated near the Çaltusuyu River, which is a tributary of the Euphrates. The town lies near the end of a fertile valley surrounded by orchards and gardens and below a small hill dominated by a ruined 13th-century walled citadel. Formerly a Byzantine stronghold known as Tephrike, it was in the mid-9th century a place of refuge for the Paulicians, who were persecuted for heresy by the Byzantine emperors but protected by the Arab caliphs. The town fell to the Turks after their victory over Byzantium in 1071 and was ruled by Dänishmend Turks until sacked by the Mongols in the second half of the 13th century. It was incorporated into the Ottoman Empire in 1516. Buildings in Divriği from the 12th and 13th centuries exhibit some of the earliest examples of Muslim Turkish art, including an architectural group built c. 1229. Pop. (2000 est.) 14,400.

Dīwālī, also spelled **DĪVĀLĪ**, one of the major religious festivals in Hinduism, lasting for five days from the 13th day of the dark half of the lunar month Āshvina to the second day of the light half of Kārttika. (The corresponding dates in the Gregorian calendar usually fall in late October and November.) The name is derived from the Sanskrit term *dīpāvālī*, meaning "row of lights," a reference to the small earthenware lamps that are filled with oil and placed in rows along the parapets of temples and houses and set adrift on rivers and

streams. The lamps are lighted on the new-moon night to bid the presence of Lakshmi, the goddess of wealth. In Bengal, however, the goddess Kālī is worshiped, and in north India the festival also celebrates the return of Rāma, Sītā, Lakshmana, and Hanumān to the city of Ayodhyā, where Rāma's rule of righteousness would commence.

The fourth day—the main **Dīwālī** festival day and the beginning of the lunar month of Kārttika—marks the beginning of the new year according to the Vikrama calendar. Merchants perform religious ceremonies and open new account books. It is generally a time for visiting, exchanging gifts, cleaning and decorating houses, feasting, setting off fireworks displays, and wearing new clothes. Gambling is encouraged during this season as a way of ensuring good luck for the coming year and in remembrance of the games of dice played by the Lord Shiva and Pārvatī on Mount Kailāsa and similar contests between Radha and Krishna. In honour of Lakshmi, female players always win.

In Jainism, **Dīwālī** is celebrated to commemorate the passing into nirvana of Mahāvīra, the most recent of the Jain Tirthankaras, or saints. The lighting of the lamps is explained as a material substitute for the light of holy knowledge that was extinguished with Mahāvīra's passing. Since the 18th century **Dīwālī** has been celebrated in Sikhism as the time when Gurū Hargobind returned to Amritsar from captivity in Gwalior—apparently an echo of Rāma's return to Ayodhyā. Residents of Amritsar are said to have lighted lamps throughout the city to celebrate the occasion.

dīwān: *see* **divan**.

dīwānī script, cursive style of Arabic calligraphy developed during the reign of the early Ottoman Turks (16th–early 17th century). It was invented by Housam Rumi and reached

Dīwānī script, 1598–99 (Oxford, Bodleian Library, MS. Laud Or. 67, fol. 77r)
By courtesy of the Bodleian Library, Oxford

its height of popularity under Süleyman I the Magnificent (1520–66). As decorative as it was communicative, *dīwānī* was distinguished by the complexity of the line within the letter and the close juxtaposition of the letters within the word.

Dīwānīyah, **ad-**, capital of al-Qādisīyah *muḥāfaẓah* (governorate), south-central Iraq. It is located in one of the nation's smallest gover-

norates and is about 100 mi (160 km) south of Baghdad, the national capital. The town lies in a riverine area about 20 mi west of a channel of the Euphrates River. Agriculture is the main occupation; palm trees, vineyards, and orchards are cultivated. Pop. (1987) 196,519.

Dix, Dorothea Lynde (b. April 4, 1802, Hampden, District of Maine, Mass., U.S.—d. July 17, 1887, Trenton, N.J.), social reformer and humanitarian whose devotion to the welfare of the mentally ill led to widespread reforms in the United States and abroad.

Dorothea Dix, portrait by S.B. Waugh, 1868; in Saint Elizabeths Hospital, Washington, D.C.

By courtesy of Saint Elizabeths Hospital, Washington, D.C.

In 1821 she opened a school for girls in Boston, where, until 1835, periods of intensive teaching were interrupted by periods of ill health. In 1841 she accepted an invitation to teach a Sunday school class in the East Cambridge (Mass.) jail. There the sight of mentally ill persons thrown into prison with criminals of both sexes disturbed her deeply. In the next 18 months she toured Massachusetts institutions where the mentally ill were confined. She revealed the shocking conditions she found in a report to the state legislature (1843). When improvements followed, she turned her attention to neighbouring states and then to those of the West and South. She saw special hospitals for mental patients built in more than 15 states and in Canada and improved treatment practiced throughout the nation. Although her efforts to secure public lands for her cause failed, she aroused a concern for the problems of mental illness in Europe as well as the U.S.

Dix, John Adams (b. July 24, 1798, Boscawen, N.H., U.S.—d. April 21, 1879, New York City), political leader and U.S. Army officer who, as secretary of the treasury of the United States (1861), issued to a treasury officer in New Orleans the famous order: "If any one attempts to haul down the American flag, shoot him on the spot."

John Dix
By courtesy of the Library of Congress, Washington D.C.

He entered the U.S. Army at the age of 14 and served in the War of 1812 and the U.S. Civil War (1861–65). Following a period of law practice (1828–30) in Cooperstown, N.Y.,

he was appointed adjutant general of New York (1830) and became a member of the Albany Regency, a politically powerful group of New York Democrats. Rising rapidly in politics, he was secretary of state and superintendent of public schools (1833–39), a member of the State Assembly (1841), and a U.S. senator from New York (1845–49). He served as postmaster of New York City (1860), was U.S. minister to France (1866–69), and, in 1872, was elected governor of New York.

Dix, Otto (b. Dec. 2, 1891, Untermaus, Thuringia, Ger.—d. July 25, 1969, Singen, Baden-Württemberg, W.Ger.), German painter and engraver who mixed compassion and Expressionist despair to create works critical of society. He was associated with the *Neue Sachlichkeit* (*q.v.*) group of painters.

Son of a railway worker, Dix was apprenticed to a decorative artist and received training in Dresden. An Impressionist at first, he experimented with various trends in modern art until he arrived at a mordantly individual style, a nightmarish vision of contemporary social reality. While teaching at Düsseldorf (c. 1922–25) he did such representative paintings and drawings as "Pimp and Girls" and "Two Sacrifices of Capitalism" (the sacrifices are a grotesque prostitute and a defaced former soldier). In 1924 he etched 50 plates, entitled "War," recording its horrors.

"Parents of the Artist," oil on canvas by Otto Dix, 1921; in the Öffentliche Kunstsammlung, Basel, Switzerland

By courtesy of the Öffentliche Kunstsammlung and the Emanuel Hoffman Stiftung, Basel, Switz.; photograph Hans Hinz

Appointed a professor at the academy in Dresden (1927), Dix was elected to the Prussian Academy (1931). The Nazi regime, however, incensed at his antimilitary works, cancelled these affiliations and barred him from exhibiting. He was jailed in 1939 on a charge of complicity in a plot on Adolf Hitler's life, but in 1945 he was drafted into the home guard army at the age of 53. He was captured and released by the French.

Dix later turned to religious mysticism, as in "Saul and David" (1945) and "Crucifixion" (1946).

Dixie, the Southern U.S. states, especially those that belonged to the Confederate States of America (1860–65). The name came from the title of a song composed in 1859 by Daniel Decatur Emmett; this tune was popular as a marching song of the Confederate Army, and was often considered the Confederate anthem.

According to the most common explanation of the name, \$10 notes issued before 1860 by the Citizens' Bank of New Orleans and used largely by French-speaking residents were imprinted with *dix* (French: "ten"); hence the land of Dixies, or Dixie Land, which applied to Louisiana and eventually the whole South.

The song "Dixie" was originally a "hooray song" or walk-around in Jerry Bryant's minstrel show, for which Emmett, a native Ohioan of Virginian parents, performed and wrote music. It was played at the inauguration of

Confederate Pres. Jefferson Davis on Feb. 18, 1861, in Montgomery, Ala.

Dixiecrat, also called STATES' RIGHTS DEMOCRAT, member of a right-wing Democratic splinter group in the 1948 U.S. presidential election organized by Southerners who objected to the civil rights program of the Democratic Party. It met at Birmingham, Ala., and on July 17, 1948, nominated Gov. Strom Thurmond of South Carolina for president and Gov. Fielding L. Wright of Mississippi for vice president. The Dixiecrats, who opposed federal regulations they considered to interfere with states' rights, carried South Carolina, Mississippi, Louisiana, and Alabama, to receive 39 electoral votes; their popular vote totalled over 1,000,000.

Dixieland, in music, a style of jazz, often ascribed to the New Orleans jazz pioneers of the early 20th century, although many believe the term better describes the styles honed by Chicago musicians in the years shortly thereafter. The term is also used in reference to the traditional jazz styles that underwent a revival during the 1940s. (See also MACROPAEDIA: Musical Forms and Genres: Jazz.)

The antecedents of jazz could be heard in the local music of several U.S. cities at the turn of the 20th century, but the centre of musical activity was New Orleans, La., and it was from there that most of the seminal figures of early jazz hailed. Much early jazz developed and flourished in the brothels, taverns, and gambling halls of Storyville, a 38-square-block red-light district of New Orleans that was established in 1897. In this segregated district, the music of such black pioneers as Buddy Bolden and Jelly Roll Morton developed parallel to the music of "Papa" Jack Laine, Nick La Rocca, and other white musicians. Theories as to jazz's origins are impossible to prove, owing to a lack of recorded evidence, but it is clear that both blacks and whites played the New Orleans style (*q.v.*) of music that would come to be tagged "Dixieland." The scant available evidence (mostly anecdotal) suggests that both groups shared many common influences and employed the New Orleans marching-band tradition of using trumpet (or cornet), clarinet, and trombone as front-line instruments.

Upon the closing of Storyville in World War I, several musicians looked elsewhere for employment. Although the notion that jazz moved "up the river" to Chicago is grossly oversimplified, it is true that Chicago became the next major urban centre of jazz in the early 1920s and that many Chicago jazz musicians hailed from New Orleans. Chicago musicians built upon the New Orleans style from the previous decade, which still showed the heavy influence of marching bands and emphasized the ensemble, rather than the soloist, as it employed a steady "oom-chuck" rhythm with emphasis squarely on the downbeats. The Chicago style (*q.v.*) incorporated more blues trademarks and, foreshadowing the swing music of the 1930s, emphasized the second and fourth beats (the offbeats) in each measure. The most important development in Chicago, however, was the emergence of the solo instrumentalist. Louis Armstrong is cited as the first important jazz soloist, and it was his playing that influenced white players of the "Chicago school," such as Jimmy McPartland, Bud Freeman, Frank Teschemacher, and Bix Beiderbecke. Though called Dixieland or "New Orleans jazz," the form thus actually had its greatest success in Chicago.

The traditional jazz revival of the 1940s— spearheaded by Bunk Johnson, an alumnus of Buddy Bolden's band—borrowed heavily from the Chicago style, and it is this music that is most often referred to as "Dixieland."

The big bands of the 1930s had been enormously popular, but many felt that their rigid ensemble approach had stifled somewhat the growth of jazz. Those who regarded the small-group setting as more conducive to jazz were divided into two camps: the "moldy figs" (traditional jazz musicians who advocated a return to the styles of the 1920s and early '30s), and the "young lions" of the burgeoning bebop movement. Older black jazz veterans figured prominently in the Dixieland revival, but, without exception, young blacks did not participate as either players or listeners; it was regarded by many as an outmoded brand of music that had become the domain of white musicians. Nevertheless, the music of the traditional revival has proved to be of great lasting value, and it is still the music heard throughout much of New Orleans, particularly during Mardi Gras time. Its traditions were carried on in later years by such popular New Orleans-area musicians as Pete Fountain and Al Hirt.

Dixon, city, seat (1834) of Lee county, northwestern Illinois, U.S., on the Rock River. In 1830 John Dixon established a ferry service and tavern there on his mail route between Peoria and Galena. Gen. Henry Atkins built Fort Dixon as a base for his campaign in 1832 against Chief Black Hawk. A bronze statue (by Leonard Crunelle) depicting the young Abraham Lincoln as a captain in the militia marks

Lincoln Monument State Memorial, Dixon, Ill.

the site on the river's north bank where Jefferson Davis, Zachary Taylor, and Lincoln met as comrades-in-arms. Dixon is the commercial centre of an agricultural region and has some industry, notably commercial printing, some light manufacturing, and food processing. Pres. Ronald Reagan spent his boyhood in Dixon, and his home has been preserved. Sauk Valley Community College (1965) is 5 miles (8 km) west. White Pines Forest and Castle Rock state parks are to the north. Inc. 1857. Pop. (2000) 15,941.

Dixon, George (b. July 29, 1870, Halifax, N.S., Can.—d. Jan. 6, 1909, New York City), U.S. boxer, first black to win a world boxing championship. He is considered one of the best fighters in the history of the bantamweight and featherweight divisions (present weight limits 118 pounds and 126 pounds, respectively).

A resident of Boston from 1887, Dixon won the world bantamweight championship by knocking out Nunc Wallace of England in the

18th round on June 27, 1890, in London. Later that year he resigned the title, after one successful defense, and subsequently fought as a featherweight. He held the championship of that class from July 28, 1891, when he knocked out Abe Willis of Australia in the fifth round in San Francisco, to Oct. 4, 1897, when he lost a 20-round decision to Solly Smith, also in San Francisco. He regained that title on Nov. 11, 1898, when he defeated Dave Sullivan in the 10th round in New York City, and he held it until Jan. 9, 1900, when he was knocked out by Terry McGovern in the eighth round, also in New York City. In 20 years of professional boxing (1886–1906) he fought 158 bouts (some boxing historians say 700), including 33 championship fights.

Dixon, Henry Horatio (b. May 19, 1869, Dublin—d. Dec. 20, 1953, Dublin), Irish botanist who investigated plant transpiration and, with John Joly, developed the tension theory of sap ascent.

Dixon studied at Trinity College, Dublin, and the University of Bonn; he became professor of botany at Trinity (1904) and director of the botanical gardens (1906). His early research included work on the cytology of chromosomes and first mitosis in certain plants. Familiarity with work on transpiration and on the tensile strength of columns of sulfuric acid and water led Dixon and Joly to experiment on transpiration. "On the Ascent of Sap" (1894) presented the hypothesis that the sap or water in the vessels of a woody plant ascends by virtue of its power of resisting tensile stress and its capacity to remain cohesive under the stress of great differences of pressure. Dixon and Joly further demonstrated that water is transported through passive vessels and not living cells.

Dixon wrote *Transpiration and the Ascent of Sap in Plants* (1914) and the textbook *Practical Plant Biology* (1922).

Dixon, Jeremiah (d. 1777, Durham, Durham, Eng.), British surveyor who, working with fellow surveyor Charles Mason, established the boundary between Maryland and Pennsylvania, known since as the Mason and Dixon Line.

Almost nothing is known of Dixon's life prior to and after his association with Mason. In 1760 the two were selected by the Royal Astronomical Society to travel to Sumatra in order to observe the transit of Venus. They got no farther than the Cape of Good Hope, however (where they did make some observations), before returning to England.

In 1763 Mason and Dixon were commissioned by the heirs of William Penn and Lord Baltimore to settle an old dispute over the boundary between Pennsylvania and Maryland. Arriving in Philadelphia in November, they began work the following month at the northeastern corner of Maryland. Proceeding along the parallel of latitude 39°43'17.6" N, they set milestones bearing a P on one side and M on the other along 244 miles of the boundary; every fifth milestone bore the Penn arms and Calvert arms on appropriate sides. Hostile Indians prevented Mason and Dixon from marking the final 36 miles, and in 1767 they returned to Philadelphia. Their work cost \$75,000, but it was ratified by the crown in 1769 and has been accepted ever since.

The Mason and Dixon Line has always been popularly regarded as the boundary between the North and the South, though it was limited to the two states of Pennsylvania and Maryland. Mason and Dixon were discharged as surveyors of the colonial boundary on Dec. 26, 1767, but they did not return to England until Sept. 9, 1768.

Dixon, Roland B(urrage) (b. Nov. 6, 1875, Worcester, Mass., U.S.—d. Dec. 19, 1934, Cambridge, Mass.), U.S. cultural anthropologist who, at the Peabody Museum of Harvard

University, organized one of the world's most comprehensive and functional anthropological libraries. He also developed Harvard into a leading centre for the training of anthropologists.

Dixon's career was spent entirely at Harvard, where he rose from assistant in anthropology (1897) to professor (1915). His initial field researches were among the Indians of California and resulted in writings, some published jointly with the ethnologist A.L. Kroeber, on ethnography, folklore, and linguistics. A notable work is *The Northern Maidu* (1905). He also made field studies in Siberia, Mongolia, the Himalayas, and Oceania.

Oriented toward the organization and interpretation of anthropological facts rather than toward field work, Dixon introduced an emphasis on the interrelationship between culture and natural environment. Less a theoretician and more a cultural historian, he noted the importance of ethnic migration in cultural change. His most ambitious work is thought to be *The Racial History of Man* (1923), in which he attempted to classify racial types and revealed the diversity of many populations, notably the Polynesians and American Indians. Another major work, *The Building of Cultures* (1928), contained a meticulous examination of cultural diffusion.

Dixon, Thomas (b. Jan. 11, 1864, Shelby, N.C., U.S.—d. April 3, 1946, Raleigh, N.C.), U.S. novelist, dramatist, and legislator who vigorously propagated white supremacy. He is chiefly remembered for his novel *The Clansman* (1905), which presented a sympathetic picture of the Ku Klux Klan. Dixon's friend D.W. Griffith used the novel as the basis for the epic film *The Birth of a Nation* (1915).

After taking a degree from Greensboro (N.C.) Law School, Dixon was admitted to the bar in 1886. He spent a year as a member of the North Carolina legislature but resigned to become a Baptist minister, serving in Raleigh, N.C., Boston, and New York City (1889–99). His first novel, *The Leopard's Spots* (1902), forms a trilogy about the South during Reconstruction with *The Clansman* and *The Traitor* (1907). He wrote other novels and some plays, and as late as 1939 he wrote yet another fictional account of black-white relations in the United States, *The Flaming Sword*. His nonfiction work includes *The Inside Story of the Harding Tragedy* (1932), written with Harry M. Daugherty, President Harding's one-time campaign manager. Although a Democrat, Dixon espoused many right-wing causes and opposed Franklin D. Roosevelt's New Deal.

diyah, in Islām, the traditional compensation due for the shedding of blood. In pre-Islamic times, the compensation required for taking a life was 10 she-camels. The figure was increased to 100 in the area where Islām originated, and this regulation was subsequently endorsed by Muḥammad.

Elaborate rules were laid down concerning injuries of various degrees of severity. The loss of one eye or a foot was fixed at 50 she-camels; a blow that penetrated the head or abdomen at 33; the loss of a tooth or a wound that penetrated the skin and exposed the bone at 5 camels. The stipulated age of the camels varied with each case, e.g., for intentional homicide: 25 she-camels that were one year old, 25 that were two years old, 25 that were three years old, and 25 that were four years old.

The stipulations changed when one or both parties were not adult, free, Muslim males. In most circumstances, a minor was not liable to pay the *diyah* at all. A woman would receive only half the *diyah* that a male would receive in identical circumstances. If a slave were killed, his *diyah* would be the same as his market value. If he were wounded, the amount of the *diyah* would correspond to the

loss reflected in his market value. The *diyyah* of a Christian or a Jew came to half or one-third that of a Muslim. If a Christian or a Jew were treacherously murdered, his murderer would be put to death. Women and children were exempt from paying the *diyyah*.

In case of intentional or unintentional murder, the perpetrator (or, in the case of his death, his heirs) was completely responsible for paying the *diyyah*. His relatives might pay for him, but they had no obligation. If the perpetrator could not pay the *diyyah* in full immediately, the time could be extended with the approval of the recipient. Owners of shops or farms were responsible for injuries sustained by their employees while at work.

The *diyyah* could be paid in silver or gold, particularly to town dwellers, who generally would not accept payment in camels. On the other hand, tent dwellers paid their *diyyahs* in camels according to established rules.

Diylā River, Arabic NAHR DIYĀLĀ, river, important tributary of the Tigris River, rising in the Zagros Mountains of western Iran near Hamadān as the Sirvān River and flowing westward across lowlands to join the Tigris just below Baghdad, Iraq. Its total length is 275 miles (443 km). The upper Diylā drains an extensive mountain area of Iran and Iraq. For 20 miles (32 km) it forms the frontier between the two countries. Thereafter it flows first into a rolling plateau country, forming part of the region known as Assyria and centred on the oil-field area of Khānaqīn, then through the Hamrīn Mountains (the southwestern boundary of Assyria) into the flat Tigris lowlands. Several dams, including the Khan Gorge, near the Iranian frontier, divert water for flood control, hydroelectric power, and the irrigation of wheat, rye, cotton, rice, and tobacco in the lower valley. Ba'qūbah, the main riparian centre, lies on the river's lower course, about 30 miles (48 km) northeast of Baghdad.

Diyarbakır, also spelled DIYARBEKİR, historically AMIDA, city, southeastern Turkey, on the right bank of the Tigris River. The name means "district (*diyar*) of the Bakr people." Amida, an ancient town predating Roman colonization in the 3rd century AD, was enlarged and strengthened under the Roman emperor Constantius II, who also erected new walls around the city (349). After a long siege, it fell to the king of Persia in 359. It changed hands frequently in the later wars between the Romans and the Persians and was in Byzantine hands when the Arabs took it (c. 639). With the weakening of 'Abbāsīd control over the region and the emergence of the Hamdānīd dynasty of Mosul (in Iraq) in the 10th century, Amida was ruled by various Arab, Turkish, Mongol, and Persian dynasties until its capture by the Ottoman sultan in 1516. Capital of a large and important province under the Ottomans, it regained its prosperity. Its loca-

tion, near the Persian frontier, also gave it strategic importance, and the town was used as a base for armies facing Persia.

The old town is still surrounded by the ancient black basalt walls that gave it the name Kara (Turkish: "Black") Amid. The triple walls, an outstanding example of Middle Eastern medieval military art, were greatly expanded and restored during the Arab and Turkish periods; they are about 3 miles (5 km) long and have numerous towers. Industries include woolen and cotton textiles and copper products; it long has been famous for its gold and silver filigree work. Tigris University in Diyarbakır was founded in 1966 as a branch of Ankara University and acquired independent status in 1973. Diyarbakır is linked by air and railroad with Ankara, and the region has a well-developed road network.

The surrounding region is part of upper Mesopotamia, comprising a large depression crossed by the Tigris River. It is separated from eastern Anatolia by the Taurus Mountains in the north and from the Mesopotamian plain by the Mardin hills in the south; the Karaca Mountain lies to the west. Agricultural products include cereals, cotton, tobacco, and fruits, notably watermelons; mineral deposits include copper and some coal and petroleum. A large proportion of the population is Kurdish. Pop. (1990) 381,144.

Dizfūl (Iran): see Dezful.

Dja River, also called NGOKO RIVER, stream in west-central Africa that forms part of the Cameroon-Congo boundary. It rises southeast of Abong-Mbang, southeastern Cameroon, and flows generally southeast past Moloundou to Ouesso, Congo, where it empties into the Sangha River (a tributary of the Congo River) after a course of about 450 miles (720 km). The Dja Faunal Reserve (Cameroon) lies along its upper course. Below Moloundou, the river is navigable by small boats throughout the year.

Djebar, Assia, original name FATIMA-ZOHRĀ IMALAYAN (b. Aug. 4, 1936, Cherchell, Alg.), one of the most talented and prolific of contemporary Algerian women writers.

Djebar's career as a novelist began in 1957 with the publication of her first novel, *La Soif* (*The Mischief*). It was followed by *Les Impatients* (1958; "The Impatient Ones"), which similarly dealt with the colonial Algerian bourgeois milieu.

The novel *Les Enfants du nouveau monde* (1962; "The Children of the New World") and its sequel *Les Alouettes naïves* (1967; "The Naive Larks") chronicle the growth of Algerian feminism and describe the contributions of Algerian women to the war for independence from France. Djebar collaborated with her husband, Walid Garn, on the play *Rouge l'aube* ("Red is the Dawn"), published in the review *Promesses* in 1969. The collection *Poèmes pour l'Algérie heureuse* ("Poems for a Happy Algeria") also appeared that year.

Djebar spent most of the war years outside Algeria, but afterward she taught history at the University of Algiers, was made department head of the French Section at the university, and became a filmmaker. In 1978 her film *Nouba des femmes du mont Chenoua* was released, the story of an Algerian woman engineer returned to Algeria after a long Western exile. *Femmes d'Alger dans leur appartement* (1980; *Women of Algiers in Their Apartment*) is a collection of novellas. Her later works include *Ombre sultane* (1987; *A Sister to Scheherazade*).

Djedefre (king of Egypt): see Redjedef.

Djefara (Africa): see Jifarah, al-.

Djelfa, also called (after 1981) EL-DJELFA, town, north-central Algeria, in the Ouled Nail Mountains at an elevation of 3,734 feet (1,138 m). It is situated between the towns of Bou Saâda and Laghouat. Djelfa town is at a point of transition between the dry, stepplike High Plateaus of the north, with their chotts (intermittent salt lakes), and the Sahara (south). The town was founded in 1852 as a French military post on a geometric plan. It serves as an important livestock market centre for the seminomadic Arab Ouled Nail confederation.

The surrounding region for centuries has been the meeting place of the Ouled Nail, who live in black-and-red striped tents and claim descent from the Prophet Muḥammad. The area is notable for its abundance of Neolithic rock carvings dating from 7000 to 5000 bc. North of Djelfa town there is an imposing physical feature known as Salt Rock (Rocher de Sel) that resulted from the erosion of rock salts and marls by rain, and to the west of the town Megalithic funerary structures are found. Pop. (1987) 84,207.

Djember (Indonesia): see Jember.

Djenné, also spelled JENNE, or DIENNÉ, ancient trading city and centre of Muslim scholarship, in southern Mali. It is situated on the floodlands of the Niger and Bani rivers, 220 miles (354 km) southwest of Timbuktu. Djenné was founded in the 13th century and served as an entrepôt between the traders of the central and western Sudan and those of Guinea's tropical forests. It was captured in 1468 (or 1473) by the Songhai emperor Sonni 'Alī. The city benefited both from its direct connection by river with Timbuktu and from its situation at the head of the trade routes to the gold mines of Bitou (now in Côte d'Ivoire), to Lobé, and to Bouré; it was also an important entrepôt for salt. By the mid-17th century, Djenné was known as a centre of Muslim learning. The city was besieged after 1818 and subsequently subdued by the Fulani ruler of Macina, Shehu Aḥmadu Lobbo, who expelled those inhabitants of whose form of Muslim worship he disapproved.

About 1861 Djenné was conquered by the Tukulor emperor al-Ḥājj 'Umar and was occupied by the French in 1893. Thereafter, its commercial functions were taken over by the town of Mopti, which is situated at the confluence of the Niger and Bani rivers to the north. Djenné is now an agricultural trade centre, of diminished importance, with several

examples of Muslim architecture, including a large mosque. Pop. (1987) 12,152.

Djerba (island, Tunisia): *see* Jarbah.

Djerid, Chott (Tunisia): *see* Jarid, Shaṭṭ al-.

Djibouti, officially REPUBLIC OF DJIBOUTI, French RÉPUBLIQUE DE DJIBOUTI, Arabic JUMHŪRIYAH JĪBŪTĪ, formerly (until 1977) FRENCH TERRITORY OF THE AFARS AND ISSAS, small country of eastern Africa, situated on the northeast coast of the Horn of Africa. Facing the Strait of Mandeb (between the Red Sea and the Gulf of Aden) on the east, Djibouti is bordered by Eritrea to the north, Ethiopia to the west and south, and the secessionist Somaliland Republic (still recognized internationally as part of Somalia) to the south. The capital is the city of Djibouti. Area 8,950 square miles (23,200 square km). Pop. (2004 est.) 466,900.

A brief treatment of Djibouti follows. For full treatment, *see* MACROPAEDIA: Eastern Africa.

For current history and for statistics on society and economy, *see* BRITANNICA BOOK OF THE YEAR.

The land. Djibouti may be divided into three principal regions: the coastal plain, deeply indented by the Gulf of Tadjoura, rising inland to less than 650 feet (200 m) above sea level; the volcanic plateaus in the country's southern and central part, rising from 1,000 to 5,000 feet (300 to 1,500 m) but bordered by sunken plains and lakes, some of which are the lowest surface elevations in Africa; and the mountain ranges in the northern part, reaching 6,654 feet (2,028 m) at Mount Mousâ. The land is bare, dry, and desolate, marked by sharp cliffs, deep ravines, burning sands, and thorny shrubs. Several sandy-bottomed streams flow in the mountain region, and a subterranean river, the Houmbouli, is an important source of water. The climate is extremely hot, with mean daily maximum temperatures at Djibouti city ranging between 84° F (29° C) in January and 106° F (41° C) in July. From late summer to the end of March, sea winds bring rain from the Indian Ocean, averaging less than 5 inches (125 mm) annually along the coast to about 20 inches (510 mm) inland. Most of Djibouti is barren desert, and the vegetation consists of low-lying thorn scrub and some grasses. There are some permanent wooded areas in the mountain re-

gions, and some palms, tamarind, and euphorbia are found in the low-lying plain. Animal life includes hyenas, antelopes, and gazelles. Only a tiny fraction of the land in Djibouti is arable, and less than one-tenth is available as pasture or rangeland.

The people. The two major Afro-Asiatic-speaking ethnic groups in Djibouti are the Afars and Somalis of the Issa clan. More than half of the population are Issas and related Somali clans; Afars constitute nearly two-fifths of the population; the rest include Yemeni Arabs and Europeans (mostly French). Both major ethnic groups were traditionally nomadic, though the Somalis have become more urbanized, and both adhere to the Sunni branch of Islām. The Afars are concentrated in the north and west of the country, and the Somalis are in the south. Official languages are French and Arabic. In the early 21st century nearly two-fifths of the total population was less than 15 years old. Djibouti city's inhabitants account for some two-thirds of the country's total population.

Many refugees escaping drought and war have fled to Djibouti from Ethiopia and Somalia since 1975. Most have settled in camps in and around Djibouti city, Dikhil, and Ali-Sabieh, placing a heavy burden on the country's environment and economy.

Economy. Djibouti has a developing market economy that is almost entirely based on trade and commercial services. Djibouti city serves as a major transshipment point for goods entering or leaving Ethiopia. The gross national product (GNP) per capita, though low by world standards, is significantly higher than those found in neighbouring African countries.

Almost all the country's land area is desert, and most food must be imported. Agriculture accounts for less than 5 percent of the gross domestic product (GDP). Livestock raising on scrub rangeland is the most important agricultural activity; extremely limited commercial crops include dates and some other fruits and vegetables. Deepwater wells have been sunk to alleviate the effects of periodic drought. Limited fishing is practiced along the coast.

Industry is also limited and includes small-scale mineral-water bottling, dairy processing, and printing concerns. Almost all consumer goods must be imported.

Transit trade and services account for about seven-tenths of the GDP. In addition to the expanding port and the Djibouti-Addis Ababa railway, there is a modern airport capable of servicing large jet aircraft, and several landlocked African countries airfreight their goods to Djibouti for reexport. Djibouti's banking sector is growing in importance, largely because of the relatively stable and easily convertible Djibouti franc, the absence of exchange controls, and Djibouti's international telecommunication services, which are some of the best in sub-Saharan Africa.

Principal exports from the region transiting Djibouti include coffee, salt, hides, dried beans, and cereals; imports, which are mainly consumed in the republic, include foodstuffs, textiles, fossil fuels, machinery, and transport

equipment. The unfavourable balance of trade is partially offset by transit taxes and harbour dues, but Djibouti depends heavily on foreign assistance, which, because of the country's strategic position, is readily available. Chief trading partners include Yemen, Saudi Arabia, Ethiopia, and Somalia.

Government and social conditions. Djibouti is a republic, governed by a president elected by the National Assembly. A prime minister heads the cabinet. The legal system is based on a mixture of traditional practices, Islāmic law, and French civil practice. The constitution, promulgated in 1992, allows for multiparty elections, but politics is dominated by the Popular Assembly for Progress (Rassemblement Populaire pour le Progrès; RPP).

Health service is provided through hospitals, clinics, multipurpose dispensaries, and medical posts. Life expectancy is about 43 years. The labour force of the country contains a large number of unemployed, and wages are generally low. Education is free but not compulsory and comprises primary, secondary, and technical education. Pôle University is located in Djibouti city. The government publishes a weekly newspaper, *La Nation*.

History. In about the 3rd century BC Ablé immigrants came from Arabia and settled generally in the north and partially in the south of what is now Djibouti. The Afars are descendants of these peoples. Later the Somali Issas pushed the Afars out of the south and settled in the coastal regions. In AD 825 Islām was brought to the area by missionaries. Arabs controlled the trade in this region until the 16th century, when the Portuguese competed for it. In 1862 France acquired Obock and in 1888 established French Somaliland (Côte Française des Somalis). Djibouti became the official capital of this French territory in 1892. A treaty with Ethiopia in 1897 ceded some territory. A railway was built to connect Djibouti with the Ethiopian hinterland, reaching Dire Dawa in 1903 and Addis Ababa in 1917. The interior of the area was effectively opened between 1924 and 1934 by the construction of roads and administrative posts. After World War II Djibouti port lost trade to the Ethiopian port of Asseb (now Aseb, Eritrea). In 1946 French Somaliland acquired the status of an overseas territory (from 1967 called the French Territory of the Afars and Issas), and in 1958 it voted to become an overseas territorial member of the French Community under the Fifth Republic. In 1977 the territory became independent as the Republic of Djibouti. The government of the new state had to deal with tension between the Afar and Issa peoples, which erupted into civil war in the early 1990s and continued until 2001. The Ethiopian-Eritrean war of 1998-2000 brought closer relations with Ethiopia, which now ships most of its cargo through Djibouti. In 2003 full multiparty elections were held in Djibouti for the first time since the country gained independence.

Djibouti, Arabic JĪBŪTĪ, port city and capital of the Republic of Djibouti. It lies on the southern shore of the Gulf of Tadjoura, which is an inlet of the Gulf of Aden. Built on three level areas (Djibouti, Serpent, Marabout) linked by jetties, the city has a mixture of old and modern architecture. Menelik Square contains the government palace. The city's climate is dry and hot.

Djibouti owes its creation as a port (c. 1888) to Léonce Lagarde, first governor of French Somaliland, as the area was then called. Shortly after it became the capital (1892), work began on the railway that linked Addis Ababa, Eth., to the port in 1917. The harbour is landlocked, covers 160 acres (65 hectares), and has been modernized and dredged to depths of 40-65 feet (12-20 m). Djibouti became a free port in 1949, and the economic life of both the city and the nation depends on the city's use as

Djibouti

an entrepôt especially between Ethiopia and the Red Sea trade and as a refueling and supply station. Trade declined during the closure (1967–75) of the Suez Canal. Guerrilla attacks on parts of the Djibouti–Addis Ababa Railway during the Ethiopian civil war in the late 1970s led to further disruption of Djibouti's economy. Drought and war during the 1980s

Place Rimbaud and the Great Mosque in Djibouti, Djibouti

A. Picou—De Wys Inc

and early '90s sent many refugees to Djibouti from Somalia and Ethiopia, swelling its population and creating an additional strain on the city's resources. Major population groups in the city are the Afars (Danakil), Issa Somalis, Arabs, Europeans (mostly French), and Asians. Pop. (1995 est.) 383,000.

Djidjelli (Algeria): see Jijel.

Djilas, Milovan, Djilas also spelled DILAS (b. June 12, 1911, Podbišće [near Kolašin], Montenegro [Yugoslavia].—d. April 20, 1995, Belgrade, Serbia), prolific political writer and former Yugoslav communist official remembered for his disillusionment with communism. Much of his work has been translated into English from Serbo-Croatian.

After receiving his law degree in 1933 from the University of Belgrade, Djilas was arrested for opposing Yugoslavia's royalist dictatorship and was imprisoned for three years. In 1937 he met Josip Broz Tito, the secretary-general of the Yugoslav Communist Party, who was to become the Communist leader of Yugoslavia. Djilas joined the party's Central Committee in 1938 and its Politburo in 1940. He played a major role in the Partisan resistance to the Germans in World War II and with the war's end in 1945 became one of Tito's leading cabinet ministers. He was active in the Yugoslav communists' assertion of their independence from the Soviet Union in 1948.

In January 1953 Djilas became one of the four vice presidents of the country, and in December he was chosen president of the Federal People's Assembly. Within a month, however, his intensifying criticism of the Communist Party and his calls for increased liberalization of the regime led to his ouster from all political posts and, in April 1954, his own resignation from the party. Djilas also received an 18-month suspended prison sentence. In 1956 he was imprisoned for writing an article in an American magazine supporting the 1956 Hungarian uprising.

In 1957 Djilas's book *The New Class* was published in the West from a smuggled manuscript. It asserted that the typical governing Communists in eastern Europe were little different from the capitalists and landowners whom they had replaced; he later renounced this theory in *The Unperfect Society* (1969). Rearrested after the publication of *The New Class*, Djilas was released in 1961 but the following year was imprisoned again for the publication in the West of *Conversations with Stalin* (1962), which was critical of the Soviet leader. He received amnesty in December 1966 and thereafter lived in Belgrade.

Among Djilas's best-known works are his four volumes of political autobiography—*Land Without Justice* (1958), *Memoir of a*

Revolutionary (1973), *Wartime* (1977), and *Rise and Fall* (1985)—which chronicle his life to the mid-1960s. Other works include *The Leper and Other Stories* (1964), the biography *Tito: The Story from Inside* (1980), and the essay collection *Of Prisons and Ideas* (1986).

Djakakarta (Indonesia): see Yogyakarta.

Djoser, also spelled ZOSER, Horus name NETJERYKHET (fl. 27th century BC), second king of the 3rd dynasty (c. 2650–c. 2575 BC) of Egypt, who undertook the construction of the earliest important stone building in Egypt. His reign, which probably lasted 19 years, was marked by great technological innovation. He became renowned as the king who brought Egypt to its first great cultural flowering. His minister, Imhotep, a talented architect and physician, was himself deified.

Djoser succeeded his brother to the throne. Through his mother, he was related to the last ruler of the 2nd dynasty. With the help of Imhotep, the king erected a tomb at Saqqārah, outside the royal capital, Memphis (southwest of modern Cairo). Built entirely of stone, the innovative structure was a departure from the traditional use of mud bricks along with stone. The greatest advance, however, was a complete alteration of the shape of the monument from a flat-topped rectangular structure to a six-stepped pyramid. Surrounding the Step Pyramid were a large number of white limestone temples used for royal rituals. The style of architecture of these buildings reproduced in minutest detail the wood, reed, and brick forms employed in utilitarian construction in Egypt, and the buildings' forms show clearly that this was a first attempt to build so extensively in stone.

The temple complex was enclosed by a wall with numerous gates, which most scholars believe reproduced the walls of Memphis. In response to the internal troubles of the 2nd dynasty, Djoser was the first king to reside exclusively at Memphis, thereby helping to make it the political and cultural centre of Old Kingdom Egypt.

Długosz, Jan, Latin JOHANNES LONGINUS (b. 1415, Brzeźnica, Pol.—d. May 19, 1480, Kraków), Polish diplomat and historian whose monumental history of Poland, the first of its kind, inspired Poles with pride in their past and helped to favourably change the attitude of educated Europeans toward Poland.

Długosz entered the service of Zbigniew Oleśnicki, bishop of Kraków, and eventually became the head of his chancery. Appointed canon of Kraków (1436), Długosz in 1449 brought back from Rome a cardinal's hat for Oleśnicki and was thereafter entrusted with a succession of missions on behalf of church and state. After Oleśnicki's death, Długosz upheld his patron's theocratic views and suffered a period of disgrace (1461–63). Unlike Oleśnicki, however, Długosz had from the start supported King Casimir IV in his Prussian policy, assisting him in the negotiations with the Teutonic Order before and during the Thirteen Years' War (1454–66) and at the peace negotiations. His relations with the king having gradually improved, Długosz was charged with the education of the royal princes in 1467.

Długosz wrote *Liber beneficiorum ecclesiae Cracoviensis* ("Book of the Benefices of the Bishopric of Kraków"), which is now a primary source for economic history. His *Historiae Polonicae* originally appeared in 12 books between 1455 and 1480 but was not published in full until 1711–12 (2 vol.). Although the work is deeply patriotic and often tendentious, it is valued as evidence of many documents no longer extant in the original.

DME (aerial navigation): see distance-measuring equipment.

Dmitry (personal name): see under Demetrius, except as below.

Dmitry, FALSE, also called PSEUDO-DEMETRIUS, Russian LZHEDMITRY, or DMITRY SAMOZVANETS, any of three different pretenders to the Muscovite throne who, during the Time of Troubles (1598–1613), claimed to be Dmitry Ivanovich, the son of Tsar Ivan IV the Terrible (reigned 1533–84) who had died mysteriously in 1591 while still a child.

After Fyodor I (reigned 1584–98), the last tsar of the Rurik dynasty, died and his brother-in-law Boris Godunov succeeded him, the first False Dmitry appeared and challenged Godunov's right to the throne. The first pretender is considered by many historians to have been Grigory (Yury) Bogdanovich Otrepyev, a member of the gentry who had frequented the house of the Romanovs before becoming the monk Grigory and who apparently sincerely believed he was the legitimate heir to the throne. He claimed to be Prince Dmitry while living in Moscow (1601–02); but, when he was threatened with banishment, he fled to Lithuania, where in 1603 he began to solicit support for a campaign to acquire the Muscovite throne.

Aided by individual Lithuanian and Polish nobles, as well as by the Jesuits, the False Dmitry gathered an army of Cossacks and adventurers and invaded Russia in the fall of 1604. His forces were defeated militarily, but he attracted followers throughout southern Russia. When Tsar Boris suddenly died in April 1605, the government army shifted its support to the pretender; Muscovite boyars murdered Boris' infant son and heir, and the False Dmitry triumphantly entered Moscow in June 1605 and was proclaimed tsar.

Dmitry, however, alienated his supporters by failing to observe the traditions and customs of the Muscovite court, by favouring the Poles who had accompanied him and Marina Mniszek (a Polish nobleman's daughter who became Dmitry's wife) to Moscow, and by attempting to engage Muscovy in an elaborate Christian alliance to drive the Turks out of Europe. In May 1606 Vasily Shuysky, one of the boyars who had turned against him, led a coup d'état, murdered the first False Dmitry, and succeeded him as tsar.

Rumours spread that Dmitry had survived the coup d'état, and in August 1607 another pretender appeared at Starodub claiming to be the recently deposed tsar. Although the second False Dmitry bore no physical resemblance to the first, he gathered a large following among Cossacks, Poles, Lithuanians, and rebels who had already risen against Shuysky. He gained control of southern Russia, marched toward Moscow, and established his headquarters (including a full court and government administration) at the village of Tushino (spring 1608).

Known thereafter as the Thief of Tushino, the second False Dmitry sent his bands to ravage northern Russia, and, after Marina Mniszek formally claimed him as her husband, he wielded authority that rivaled Shuysky's. In the spring of 1610, however, Shuysky, aided by Swedish troops, ejected the Thief of Tushino from northern Russia and forced him to flee to Kaluga. The second False Dmitry continued to contend for the Muscovite throne until one of his own followers fatally wounded him in December 1610.

In March 1611 a third False Dmitry, who has been identified as a deacon called Sidorka, appeared at Ivangorod. He gained the allegiance of the Cossacks (March 1612), who were ravaging the environs of Moscow, and of the inhabitants of Pskov, thus acquiring the nickname Thief of Pskov. In May 1612 he was betrayed and later executed in Moscow.

Dmitry (II) Donskoy, byname of DMITRY IVANOVICH (b. Oct. 12, 1350, Moscow [Rus-

sia)—d. May 19, 1389, Moscow), prince of Moscow, or Muscovy (1359–89), and grand prince of Vladimir (1362–89), who won a victory over the Golden Horde (Mongols who had controlled Russian lands since 1240) at the Battle of Kulikovo (Sept. 8, 1380).

Son of Ivan II the Meek of Moscow (reigned 1353–59), Dmitry became ruler of Muscovy when he was only nine years old; three years later he convinced his suzerain, the great khan of the Golden Horde, to transfer the title grand prince of Vladimir (which had been held by Muscovite princes from 1328 to 1359) from Dmitry of Suzdal to him.

In addition to gaining the title grand prince of Vladimir for himself, Dmitry strengthened his position by increasing the territory of the principality of Muscovy, by subduing the princes of Rostov and Ryazan, and by deposing the princes of Galich and Starodub. While the Golden Horde was suffering from internal conflicts, Dmitry stopped making regular tribute payments and encouraged the Russian princes to resist the Mongols' raids. In 1378 the Russians defeated an army of the Horde on the Vozha River.

Subsequently, Mamai, the Mongol general who was the effective ruler of the western portion of the Golden Horde, formed a military alliance with neighbouring rulers for the purpose of subduing the Russians. Confronting the Mongols on the Don River, however, in the bloody battle on Kulikovo Pole ("Snipes' Field"), Dmitry routed Mamai's forces; for his victory Dmitry was honoured with the surname Donskoy ("of the Don"). Shortly afterward, however, his lands were re-subjected to Mongol domination when the Mongol leader Tokhtamysh overthrew Mamai (1381), sacked Moscow (1382), and restored Mongol rule over the Russian lands.

Dmowski, Roman (b. Aug. 9, 1864, Kamionek, near Warsaw, Pol., Russian Empire—d. Jan. 2, 1939, Drodzowo, Pol.), Polish statesman, a leader of Poland's struggle for national liberation, and the foremost supporter of cooperation with Russia as a means toward achieving that goal.

As a student in Warsaw, Dmowski involved himself in the movement for Polish liberation and in 1895 helped found the influential *Przegląd Wszechpolski* ("All-Polish Review") at Lwów (modern Lviv, Ukraine). A leader of the National Democratic Party from its foundation (1897), he opposed revolutionary methods of establishing an independent Poland and favoured an autonomist solution to national aspirations within the Russian Empire. During

Dmowski, drawing by Lela Pawlikowska, 1929; in the collection of Dr. T. Bielecki

By courtesy of Dr. T. Bielecki

the Russo-Japanese War (1904–05) he actively combated the plans of Polish revolutionaries—especially Józef Piłsudski, the future president of Poland—to secure an understanding with Japan as a prelude to national insurrec-

tion. He later distinguished himself in the second and third Russian Dumas (legislative assemblies) as the chief spokesman for Polish collaboration with Russia. By 1912, however, his policy had been largely discredited, and in October of that year he failed to be elected to the fourth Duma.

During the early months of World War I, Dmowski helped form a "National Committee" that sought to achieve Polish national aims through cooperation with Russia and its Western allies. From the summer of 1915, however, he looked solely to the Western powers for deliverance and discarded his autonomist program for one demanding full national sovereignty for Poland. In August 1917 he formed a National Committee at Lausanne, Switz., which later was recognized by the Allies as the official representative of Polish interests.

After the war Dmowski represented the new Polish national government at the Paris Peace Conference, and in June 1919 he signed the Treaty of Versailles. He subsequently sat in the constituent Sejm (Polish national assembly) until 1922 and briefly served as foreign minister during 1923, but thereafter he largely retired from active politics. His book *Niemcy, Rosya i kwestya polska* (1908; "Germany, Russia, and the Polish Question") is an exposition of his prewar views.

DMT, abbreviation of DIMETHYLTRYPTAMINE, powerful, naturally occurring hallucinogenic compound structurally related to the drug LSD (lysergic acid diethylamide). DMT blocks the action of serotonin (a transmitter of nerve impulses) in brain tissue. It is inactive when taken by mouth and produces effects only when injected, sniffed, or smoked. The hallucinatory action begins about five minutes after administration by injection and lasts for about an hour. Naturally formed DMT has been found in the body fluids of persons suffering from schizophrenia. It also has been synthesized chemically. DMT is contained in cohoba, the hallucinogenic snuff made from the seeds of *Piptadenia peregrina* and used by the Indians of Trinidad and the Yanos in northern South America at the time of early Spanish explorations.

Dmytryk, Edward (b. Sept. 4, 1908, Grand Forks, B.C., Can.—d. July 1, 1999, Encino, Calif., U.S.), American motion-picture director, one of the "Hollywood Ten," a group of film-industry people who were blacklisted for their alleged communist association. His notable films include *Crossfire* (1947), *The Caine Mutiny* (1954), *The Young Lions* (1958), and a film noir classic *Murder, My Sweet* (1945; also entitled *Farewell My Lovely*).

Dmytryk was the son of Ukrainian immigrants. He left home at the age of 14 and soon found a job as a projectionist for the Famous Players-Lasky studios. He completed one year of college before returning to work full-time as a projectionist. During the 1930s he worked as a film editor for Paramount studios and became involved with other aspects of filmmaking. His first film, *The Hawk*, was independently made in 1935. He became a U.S. citizen in 1939. In 1939–40 he made several low-budget films for Paramount, but he hit his stride with the film *Murder, My Sweet*. The huge success of *Crossfire*, which received five Academy Award nominations, was marred by Dmytryk's subpoena to appear before the House Un-American Activities Committee (HUAC) for his alleged collusion with others in a conspiracy to take over the Screen Directors' Guild in the interests of the American Communist Party. When he refused to answer charges, he was cited for contempt of Congress and was blacklisted.

In 1948 Dmytryk went to England and made two films there—notably *Salt to the Devil* (1949; also published as *Give Us This Day*)—before being ordered to the United States to renew his passport. He was forced to serve six

months in prison for contempt of Congress and decided to become a friendly witness for HUAC. Thereafter he made *The Sniper* (1952), *The Caine Mutiny*, *The Young Lions*, and a great many lesser motion pictures. He taught at the University of Texas and at the University of Southern California (Los Angeles). His autobiography, *It's a Hell of a Life, But Not a Bad Living*, was published in 1978.

DNA, abbreviation of DEOXYRIBONUCLEIC ACID, organic chemical of complex molecular structure that is found in all prokaryotic and eukaryotic cells and in many viruses. DNA codes genetic information for the transmission of inherited traits.

A brief treatment of DNA follows. For full treatment, see MACROPAEDIA: Genetics and Heredity, Principles of; Biochemical Components of Organisms.

DNA was first discovered in 1869, but its role in genetic inheritance was not demonstrated until 1943. In 1953, James Watson and Francis Crick determined that the structure of DNA is a double-helix polymer, a spiral consisting of two DNA strands wound around each other. Each strand is composed of a long chain of monomer nucleotides. The nucleotide of DNA consists of a deoxyribose sugar molecule to which is attached a phosphate group and one of four nitrogenous bases: two purines (adenine and guanine) and two pyrimidines (cytosine and thymine). The nucleotides are joined together by covalent bonds between the phosphate of one nucleotide and the sugar of the next, forming a phosphate-sugar backbone from which the nitrogenous bases protrude. One strand is held to another by hydrogen bonds between the bases; the sequencing of this bonding is specific—i.e., adenine bonds only with thymine, and cytosine only with guanine.

The configuration of the DNA molecule is highly stable, allowing it to act as a template for the replication of new DNA molecules, as well as for the production (transcription) of the related RNA (ribonucleic acid) molecule. A segment of DNA that codes for the cell's synthesis of a specific protein is called a gene.

DNA replicates by separating into two single strands, each of which serves as a template for a new strand. The new strands are copied by the same principle of hydrogen-bond pairing between bases that exists in the double helix. Two new double-stranded molecules of DNA are produced, each containing one of the original strands and one new strand. This "semi-conservative" replication is the key to the stable inheritance of genetic traits.

Within a cell, DNA is organized into dense protein-DNA complexes called chromosomes. In eukaryotes, the chromosomes are located in the nucleus, although DNA also is found in mitochondria and chloroplasts. In prokaryotes, which do not have a membrane-bound nucleus, the DNA is found as a single circular chromosome in the cytoplasm. Some prokaryotes, such as bacteria, and a few eukaryotes have extrachromosomal DNA known as plasmids, which are autonomous, self-replicating genetic material. Plasmids have been used extensively in recombinant DNA technology to study gene expression.

The genetic material of viruses may be single- or double-stranded DNA or RNA. Retroviruses carry their genetic material as single-stranded RNA and produce the enzyme reverse transcriptase, which can generate DNA from the RNA strand.

DNA fingerprinting, also called DNA TYPING, in genetics, method of isolating and making images of sequences of DNA (deoxyribonucleic acid). The technique was developed in 1984 by the British geneticist Alec Jeffreys, after he noticed the existence of certain sequences of DNA (called minisatellites) that do not contribute to the function of a gene but are repeated within the gene and in

other genes of a DNA sample. Jeffreys also determined that each organism has a unique pattern of these minisatellites, the only exception being multiple individuals from a single zygote (e.g., identical twins).

The procedure for creating a DNA fingerprint consists of first obtaining a sample of cells containing DNA (e.g., from skin, blood, or hair), extracting the DNA, and purifying it. The DNA is then cut at specific points along the strand with substances called restriction enzymes. This produces fragments of varying lengths that are sorted by placing them on a gel and then subjecting the gel to an electric current (electrophoresis): the shorter the fragment the more quickly it will move toward the positive pole (anode). The sorted, double-stranded DNA fragments are then subjected to a blotting technique in which they are split into single strands and transferred to a nylon sheet. The fragments undergo autoradiography in which they are exposed to DNA probes—pieces of synthetic DNA that have been made radioactive and that bind to the minisatellites. A piece of X-ray film is then exposed to the fragments, and a dark mark is produced at any point where a radioactive probe has become attached. The resultant pattern of these marks can then be analyzed.

If only a small amount of DNA is available for fingerprinting, a polymerase chain reaction (PCR) may be used to create thousands of copies of a DNA segment. PCR is an automated procedure in which certain oligonucleotide primers are used to repeatedly duplicate specific segments of DNA. Once an adequate amount of DNA has been produced, the exact sequence of nucleotide pairs in a segment of DNA can be determined using one of several biomolecular sequencing methods. New automated equipment has greatly increased the speed of DNA sequencing and made available many new practical applications, including pinpointing segments of genes that cause genetic diseases, mapping the human genome, engineering drought-resistant plants, and producing biological drugs from genetically altered bacteria.

Dnieper River, Ukrainian ДНІПРО, Russian ДНЕПР, Belorussian ДНЕПРО, river of Europe, the fourth longest (1,367 miles [2,200 km]) after the Volga, Danube, and Ural rivers. The Dnieper rises on the southern slopes of the Valdai Hills west of Moscow in Smolensk *oblast* (province), western Russia, and flows in a generally southern direction through Belarus and Ukraine and then into the Dnieper estuary of the Black Sea.

A brief treatment of the Dnieper River follows. For full treatment, see MACROPAEDIA: Europe.

The river's course can be divided roughly into three parts: the swampy upper Dnieper (800 miles [1,300 km] long) located as far downstream as Kiev, where about four-fifths of the Dnieper River basin's annual runoff forms; the forest-steppe region of the middle Dnieper (340 miles [550 km] long); and the semiarid Black Sea Lowland region of the lower Dnieper (200 miles [320 km] long). The major tributaries in its drainage basin of 195,000 square miles (505,000 square km) are the Desna, Sozh, Berezhina, Vorskla, Teteriv, and Pripet rivers. The climate of the Dnieper basin is continental, and annual precipitation ranges from 30 to 32 inches (760 to 810 mm) in the north to about 18 inches (460 mm) in the south. More than 300 hydroelectric plants operate in the Dnieper basin, supplying water to the Donets Basin and Kryvyi Rih industrial regions and, for irrigation, to the arid lands of southern Ukraine and Crimea. The Kremenchuk, Kakhovka, and Dnieper are among the major hydroelectric power stations on the river. The mean annual runoff of the river is 13 cubic miles (54 cubic km), but there is considerable yearly variation. The water of

the Dnieper is low in minerals. More than 60 species of fish are found in the Dnieper, including pike, carp, roach, goldfish, whitefish, catfish, perch, and herring. The construction of dams and reservoirs has deepened the river and facilitated navigation for about 1,042 miles (1,677 km) during the 10 months of the year when it is not frozen. The principal cargoes are coal, ore, building materials, and other bulk freight. The chief ports on the Dnieper are Drogobuzh and Smolensk (Russia), Orsha (Belarus), and Kiev and Kherson (Ukraine).

Dniester River, Ukrainian ДНІСТРО, Russian ДНЕСТР, Romanian NISTRUL, Moldovan NISTRU, Turkish TURLA, river of southwestern Ukraine and of Moldova, rising on the north side of the Carpathian Mountains and flowing south and east for 840 miles (1,352 km) to the Black Sea near Odessa. It is the second longest river in Ukraine and the main water artery of Moldova.

The Dniester and its tributaries drain a long, narrow basin that is about 28,000 square miles (72,000 square km) in area but is nowhere more than about 60–70 miles (100–110 km) wide. The river's basin is bounded on the north by the Volyn-Podilsk Upland and on the south of the river's upper course by the Carpathian Mountains. Farther to the south are hilly plains and the Bessarabian Upland, and at the southeasternmost end of the basin is the Black Sea Lowland. The estuary of the Dniester is formed by the incursion of the sea into the lower Dniester River valley, forming a shallow basin that is separated from the sea by a narrow strip of land. The Dniester has many tributaries, only 15 of which are more than 60 miles (95 km) long. They include the Stryi, Zolota Lypa, Strypa, Seret, Zbruch, Smotrych, Ushytsya, Murafa, Răut, Bâc, and Botna.

The climate of the river basin is humid, with warm summers. Annual precipitation varies from 40 to 50 inches (1,000 to 1,250 mm) in the Carpathians down to 20 inches (510 mm) near the Black Sea. A large proportion of the land of the basin is under cultivation.

The Dniester frequently floods, causing extensive damage to settled areas. The water level in its middle course varies by 25–35 feet (7.5–10.5 m) at different times of the year because of melting snow and rainfall in the upper part of its basin. The river's average discharge is about 10,000 cubic feet (300 cubic m) per second, but it has been known to reach 250,000 cubic feet (7,100 cubic m) per second or more at times of flood. Freezing usually occurs at the end of December or the beginning of January and lasts about two months; although in some years there is no icebound period.

Although the basin of the Dniester is densely populated, there are no large towns along the river itself. Lviv and Ternopil (Ukraine), Chişinău (Moldova), and other urban centres lie above the main valley on tributaries.

The Dniester is navigable for about 750 miles (1,200 km) from its mouth; shipping lines run from Soroca to Dubăsari (both in Moldova) and from Dubăsari to the sea. Navigation is made difficult on the lower reaches by shallow water and sandbars. The river is used extensively for carrying logs, which are brought together at the mouths of the Carpathian tributaries and rafted downstream. Fishing is of little importance except near the coast. In the lower reaches and in the Dubăsari Reservoir there are fish hatcheries for sturgeon, whitefish, pike perch, and carp.

Dniprodzerzhynsk, Russian ДНЕПРОДЗЕРЖИНСК, formerly (until 1936) КАМЕНСКО-Е, city, Dnipropetrovsk *oblast* (province), southern Ukraine, along the Dnieper River. Founded about 1750 as the Cossack settlement of Kamenskoye, the town grew after 1889 with the developing metallurgical indus-

try. The Soviets renamed it Dneprodzerzhinsk in 1936. A large, modern iron and steel plant produces high-grade steels; there are also rolling-stock, cement, coke-chemical, and nitrate-fertilizer plants. In 1964 a dam and hydroelectric station were completed on the Dnieper just above Dniprodzerzhynsk. Most of the largest factories are in the central parts of the city, but there is also recent industrial and residential development to the south and southwest. There are a metallurgical institute and several technical schools. Pop. (1993 est.) 287,000.

Dnipropetrovsk, Russian ДНЕПРОПЕТРОВСК, *oblast* (province), southern Ukraine. It lies astride the Dnieper River, which there comprises three reservoirs dammed for hydroelectric power. The *oblast* consists of rolling plains of loess-covered sedimentary rocks, largely dissected by erosion gullies. In the valleys are outcrops of underlying ancient crystalline rocks. The climate is continental, with hot summers and cold winters, the latter modified by incursions of warm air from the Black Sea. The *oblast*, formed in 1932, is important for its mineral wealth. Around Kryvyi Rih are huge deposits of iron ore, and in the Nikopol-Marhanets area are rich manganese deposits that are estimated to be among the largest in the world. Titanium is mined at Vilnohirsk; natural gas is extracted at Pereshchepyne; and some coal is extracted in the east. These minerals are the basis of large-scale heavy industry in the *oblast*'s four large cities—Dnipropetrovsk city (the *oblast* headquarters), Kryvyi Rih, Dniprodzerzhynsk, and Nikopol—which engage in iron and steel production and in a wide range of heavy engineering. Agriculture is also important in the *oblast*, especially the cultivation of winter wheat, corn (maize), spring barley, sunflowers, fodder crops, and melons. Area 12,300 square miles (31,900 square km). Pop. (1991 est.) 3,918,600.

Dnipropetrovsk, Russian ДНЕПРОПЕТРОВСК, formerly (until 1926) ЕКАТЕРИНОСЛАВ, or ЕКАТЕРИНОСЛАВ, city and administrative centre, Dnipropetrovsk *oblast* (province), south-central Ukraine. It lies along the Dnieper River, near its confluence with the Samara. Founded in 1783 as Yekaterinoslav on the river's north bank, the settlement was moved to its present site on the south bank in 1786. The community was known as Novorossiysk from 1796 to 1802, when its old name was restored and it became a provincial centre. Despite the bridging of the Dnieper in 1796 and the growth of trade in the early 19th century, Yekaterinoslav remained small until industrialization began in the 1880s, when railways were built to Odessa, the Donets Basin, and Moscow. In 1926 the Soviets renamed it Dnepropetrovsk.

Dnipropetrovsk has developed into one of the largest industrial cities of Ukraine. With iron ore from Kryvyi Rih, manganese from Nikopol, coal from the Donets Basin, and electric power from the cascade of hydroelectric plants on the Dnieper, a huge iron and steel industry has grown up in the city; and castings, plates, sheets, rails, tubes, and wire are produced. Large engineering industries make electric locomotives, agricultural machinery, mining and metallurgical equipment, presses, and other heavy machinery, as well as light-industrial machinery and radio equipment. Coke-based chemicals, tires, plastics, paint, clothing, footwear, foodstuffs, and other materials are also produced. Dnipropetrovsk has a university and teaching institutes of mining, agriculture, chemical technology, metallurgy, medicine, and railway and constructional engineering. Cultural amenities include several theatres and a philharmonic hall. Newer suburbs have spread to

the north bank. The neighbouring suburbs of Igren and Pridneprovsk were annexed in the 1970s. Pop. (1991 est.) 1,189,300.

DNVP: see German National People's Party.

Dobell, Sydney Thompson, pseudonym SYDNEY YENDYS (b. April 5, 1824, Cranbrook, Kent, Eng.—d. Aug. 22, 1874, Nailsworth, Gloucestershire), English writer of erratic poetry characterized by formlessness, chaotic imagery, and exaggerations of passion—one of a group of poets of what the writer Charles Kingsley called the Spasmodic school.

Dobell's long dramatic poem *The Roman* (1850) was hailed by the critics and secured for its author the acquaintance of many notable figures in liberal politics and in literature. *The Roman* celebrated the revolutionary year of 1848. Another long poem, *Balder* (intended as part of a trilogy), was not appreciated and

Dobell, portrait by Briton Riviere in the National Portrait Gallery, London

was burlesqued in *Firmilium: . . . a Spasmodic Tragedy* (1854) by William Edmondstone Aytoun. The vague aesthetic of the Spasmodic school was expressed by Dobell in a number of essays collected in 1876 as *Thoughts on Art, Philosophy and Religion*. Dobell also wrote lyrics and, with Alexander Smith, a sonnet sequence on the Crimean War.

Döbereiner, Johann Wolfgang (b. Dec. 13, 1780, Hof an der Saale [Germany]—d. March 24, 1849, Jena), German chemist whose observation of similarities among certain elements anticipated the development of the periodic system of elements.

As a coachman's son, Döbereiner had little opportunity for formal schooling, but he was apprenticed to an apothecary, read widely, and attended learned science lectures. Eventually he was able to attend the University of Jena, where he became an assistant professor (1810) and later was supervisor of science instruction. He was a lifelong friend of Johann Wolfgang von Goethe.

During the 1820s Döbereiner's experiments with the ignition of hydrogen on contact with powdered platinum led the Swedish chemist J.J. Berzelius to develop the concept of catalysis. Toward the end of the decade Döbereiner found that the properties of bromine, a liquid, seem halfway between those of chlorine gas and the solid iodine. He recalled a comparable gradation of properties in two other sequences—calcium, strontium, barium; and sulfur, selenium, tellurium. He showed that in each triad the mean of the lightest and heaviest atomic weights approximated the atomic weight of the middle element. But he could not substantiate his hypothesis with a sufficient number of triads, and his findings were regarded in his time as merely interesting curiosities. Döbereiner also discovered the organic compound furfural and developed the separation of calcium and magnesium.

Doberman pinscher, breed of working dog developed in Apolda, Ger., by Louis Dober-

mann, a night watchman and keeper of a dog pound, in the late 1800s. The Doberman pinscher is a sleek, agile, and powerful dog

Doberman pinscher
Sally Anne Thompson

standing 24 to 28 inches (61 to 71 cm) and weighing 60 to 75 pounds (27 to 34 kg). It has a short, smooth coat, black, blue, fawn, or red, with rust markings on the head, throat, chest, base of the tail, and feet. The breed has a reputation for fearlessness, alertness, loyalty, and intelligence. It has been used in police and military work, as a watchdog, and as a guide dog for the blind.

Döblin, Alfred (b. Aug. 10, 1878, Stettin, Ger.—d. June 26, 1957, Emmendingen, near Freiburg im Breisgau, W.Ger.), German novelist and essayist, the most talented narrative writer of the German Expressionist movement.

Döblin studied medicine and became a doctor, practicing psychiatry in the workers' district of the Alexanderplatz in Berlin. His Jewish ancestry and socialist views obliged him to leave Germany for France in 1933 after the Nazi takeover, and in 1940 he escaped to the United States, where he converted to Roman Catholicism in 1941. He returned to Germany in 1945 at the war's end but resettled in Paris in the early 1950s.

Although Döblin's technique and style vary, the urge to expose the hollowness of a civilization heading toward its own destruction and a quasi-religious urge to provide a means of salvation for suffering humanity were two of his constant preoccupations. His first successful novel, *Die drei Sprünge des Wang-Lun* (1915; *The Three Leaps of Wang-lun*), is set in China and describes a rebellion that is crushed by the tyrannical power of the state. *Wallenstein* (1920) is a historical novel, and *Berge, Meere und Giganten* (1924; "Mountains, Seas, and Giants"; republished as *Giganten* in 1932) is a merciless anti-utopian satire.

Döblin's best-known and most Expressionistic novel, *Berlin Alexanderplatz* (1929; *Alexanderplatz, Berlin*), tells the story of Franz Biberkopf, a Berlin proletarian who tries to rehabilitate himself after his release from jail but undergoes a series of vicissitudes, many of them violent and squalid, before he can finally attain a normal life. The book combines interior monologue (in colloquial language and Berlin slang) with a somewhat cinematic technique to create a compelling rhythm that dramatizes the human condition in a disintegrating social order.

Döblin's subsequent books, which continue to focus on individuals destroyed by opposing social forces, include *Babylonische Wandlung* (1934; "Babylonian Wanderer"), sometimes described as a late masterpiece of German Surrealism; *Pardon wird nicht gegeben* (1935; *Men Without Mercy*); and two unsuccessful trilogies of historical novels. He also wrote essays on political and literary topics, and his *Reise in Polen* (1926; *Journey to Poland*) is a stimulating travel account. Döblin recounted

his flight from France in 1940 and his observations of postwar Germany in the book *Schicksalsreise* (1949; *Destiny's Journey*).

Dobrich, also spelled DOBRIČ, also called (1949–91) TOLBUKHIN, town, northeastern Bulgaria. It lies on the road and railway line between Varna and Constanța, Rom., and is a long-established market town. Under Turkish rule from the 15th century until 1878, the town was called Bazardzhik; after liberation it became Dobrich. While part of Romania from 1913 to 1940, it was known as Bazar-gic; it was renamed (1949–91) for the Soviet marshal Fyodor Ivanovich Tolbukhin, who captured it from the Germans in 1944.

Its industries, largely connected with agriculture, include ensilage, flour milling, baking, and vegetable-oil extraction. Other industries produce textiles, furniture, and agricultural-machinery parts. Pop. (1991 est.) 115,789.

Dobrolyubov, Nikolay Aleksandrovich (b. Jan. 24 [Feb. 5, New Style], 1836, Nizhny Novgorod, Russia—d. Nov. 17 [Nov. 29], 1861, St. Petersburg), radical Russian utilitarian critic who rejected traditional and Romantic literature.

Dobrolyubov, the son of a priest, was educated at a seminary and a pedagogical institute. Early in his life he rejected traditionalism and found his ideal in progress as represented by Western science. In 1856 Dobrolyubov began contributing to *Sovremennik* ("The Contemporary"), an influential liberal periodical, and from 1857 until his death he was chief critic for that journal. He was perhaps the most influential critic after Vissarion Belinsky among the radical intelligentsia; his main concern was the criticism of life rather than of literature. He is perhaps best known for his essay "What is Oblomovism" (1859–60). The essay deals with the phenomenon represented by the character Oblomov in Ivan Goncharov's novel of that name. It established the term Oblomovism as a name for the superfluous man of Russian life and literature.

Dobrovský, Josef (b. Aug. 17, 1753, Gyarmat, Hung.—d. Jan. 6, 1829, Brno, Moravia, Austrian Empire [now in Czech Republic]), scholar of the Czech language, antiquary, and a principal founder of comparative Slavic linguistics.

Dobrovský, detail of an oil painting by J. Tkadlík, 1821; in the Museum of Czech Literature, Prague

By courtesy of P.N.P. Muzeum ceske literatury, Prague

Educated for the Roman Catholic priesthood, Dobrovský devoted himself to scholarship after the 1773 dissolution of the Jesuit Order. He was tireless in his research of ancient Slavic manuscripts, and he traveled widely, notably to Russia and Sweden in 1792, in search of works removed during the Thirty Years' War. His textual criticism of the Bible led him to study Old Church Slavonic and, subsequently, the Slavic languages as a group. His erudition ultimately extended to all fields of Slavic literature, language, history, and antiquities.

The first of his three most important works was *Geschichte der böhmischen Sprache und*

Litteratur (1792; "History of the Bohemian Language and Literature"), which included considerations of many earlier works long suppressed because of their Protestant religious content. His grammar of Czech, *Lehrgebäude der böhmischen Sprache* (1809; "Learning System of the Bohemian Language"), codified the language and brought order into the usage of the literary language that had come to be neglected in the preceding 150 years. The foundation of comparative Slavic studies was laid in Dobrovský's grammar of Old Church Slavonic (1822).

Dobruja, Romanian DOBROGEA, Bulgarian DOBRUDZHA, a region of the Balkan Peninsula, situated between the lower Danube River and the Black Sea. The larger, northern part belongs to Romania, the smaller, southern part to Bulgaria. It is a tableland of some 8,970 square miles (23,000 square km) in area, resembling a steppe with maximum elevations of 1,532 feet (467 m) in the north and 853 feet (260 m) in the south, where the surface is creased by ravines. The continental climate is moderated by the Black Sea, and average temperatures range between 25° F (−4° C) in January and 73° F (23° C) in July.

Owing to its openness to the sea and its position as a zone of passage between the Balkans and the steppe north of the Black Sea, the population of the Dobruja has been diverse. The majority in the north are Romanian and in the south Bulgarian, but, despite assimilation and emigration, significant minorities, notably Turks and Tatars, remain. The inhabitants are engaged primarily in agriculture, especially in the raising of grains and in viticulture. Under the communists, from the 1940s, industrialization made rapid progress. Besides food processing and fishing, major industries—notably metallurgy and chemicals—developed around Constanța, the largest city and Romania's main seaport.

The earliest inhabitants of the Dobruja were the Getae, or Getians, a Thracian people whom Greek colonists encountered when they established trading cities on the Black Sea coast in the 6th century BC. Between the 1st century BC and the 3rd century AD, Rome dominated the region, which was known as Scythia Minor, and from the 5th to the 11th centuries Byzantine rule was contested by successive waves of nomadic peoples, including Huns, Avars, Slavs, Bulgars, Pechenegs, and Cumans. In the 14th century a despotate headed by a Bulgarian named Dobrotitsa encompassed the region (Dobruja may mean "Land of Dobrotitsa"). Mircea, prince of Wallachia (1386–1418); also claimed the region, but by 1419 the Ottomans had incorporated it into their empire. During the next 450 years significant demographic changes occurred through the large-scale settlement of Anatolian Turks and Crimean Tatars. The Treaty of Berlin (1878) brought Ottoman rule to an end by awarding Romania most of the Dobruja and attaching the southern portion (the so-called Quadrilateral) to the principality of Bulgaria. Romania obtained the Quadrilateral after the Second Balkan War in 1913, but in 1940 it was forced to return that portion to Bulgaria and to accept an exchange of population. A new frontier was established by the Peace Treaty of Paris (1947).

Dobrynin, Anatoly Fyodorovich (b. Nov. 16, 1919, Krasnaya Gorka, Russia), Soviet diplomat, ambassador to the United States (1962–86), and dean of the Washington, D.C., diplomatic corps (1979–86).

The son of a worker, Dobrynin graduated from the Sergo Ordzhonikidze Moscow Aviation Institute in 1942 and worked as an engineer at an aircraft plant. In 1944–46 he studied at the Higher Diplomatic School of the Ministry of Foreign Affairs (becoming a Communist Party member in 1945) and thereafter served in the Moscow foreign office until 1952,

when he was sent to Washington, D.C., first as counselor (1952–54) and then as the second-ranking minister-counselor (1954–55). From 1955 to 1957 he was again based in Moscow, and from 1957 to 1960 he held posts in the United Nations Secretariat in New York City.

Dobrynin was appointed Soviet ambassador to the United States by Nikita Khrushchev in March 1962 and became a highly visible presence on the Washington scene. His long tenure as ambassador—spanning five Soviet leaders and six U.S. presidents—provided a vital continuity to U.S.-Soviet relations during the Cold War. In 1986 he was called back to Moscow by Mikhail Gorbachev to serve as head of the international department of the Communist Party's Secretariat. He retired in 1988.

Dobson, Austin, in full HENRY AUSTIN DOBSON (b. Jan. 18, 1840, Plymouth, Devonshire, Eng.—d. Sept. 2, 1921, London), English poet, critic, and biographer whose love and knowledge of the 18th century lent elegance to his poetry and inspired his critical studies.

In 1856 Dobson entered the Board of Trade, where he remained until his retirement in 1901. Married in 1868, he became a father of 10 and lived in the London suburb of

Austin Dobson, detail of a portrait by Frank Brooks, 1911; in the National Portrait Gallery, London

Ealing until his death at the age of 81. His first collection of poems, *Vignettes in Rhyme* (1873), was followed by *Proverbs in Porcelain* (1877). In these and in *At the Sign of the Lyre* (1885), Dobson showed the polish, wit, and restrained pathos that made his verses popular. The ease with which he handled the artificial French forms—the ballade, the triollet, and the rondeau—helped to revive their use in English. After 1885 Dobson was chiefly occupied with biographical and critical works, including books on Henry Fielding, Horace Walpole, William Hogarth, and Fanny Burney that revealed careful research into, and sympathy with, 18th-century life. Three series of *Eighteenth-Century Vignettes* (1892–96) and *A Paladin of Philanthropy* (1899 and 1901) typify his delicate prose style.

Dobson, William (b. 1610, London, Eng.—d. Oct. 28, 1646, London), English portrait painter, one of the first distinguished native English painters.

While an apprentice to a stationer and picture dealer, the young Dobson began to copy the pictures of Titian and Anthony Van Dyck and also to draw pictures from life. Van Dyck, happening to pass a shop in Snow Hill where one of Dobson's pictures was displayed, sought out the artist and presented him to Charles I, who took Dobson under his protection and not only sat for him several times for his own portrait but also had the Prince of Wales, Prince Rupert, and many others do the same. The king had a high opinion of his artistic ability, styled him the English Tintoretto, and appointed him sergeant-painter on the death of Van Dyck. After Charles's fall, Dobson was reduced to great poverty and died at

the age of 36. Examples of Dobson's portraits are to be seen at Blenheim and several other country seats throughout England.

dobsonfly, any insect of the family Corydalidae (order Megaloptera) with four net-veined wings. Dobsonflies are found in North and South America, Asia, Australia, and Africa.

Dobsonfly (*Corydalus cornutus*)

Henry C. Johnson

Corydalus cornutus is a large insect with a wingspread of about 13 cm (5 inches). The jaws (or mandibles), considerably larger in the male than in the female, are characteristic of the insect's sexual dimorphism and may exceed 2.5 cm. Females lay up to about 3,000 eggs in whitish clusters near streams; after the eggs hatch, the young larvae crawl to the water and mature there in two or three years. The maturing larvae, large (sometimes 8 cm long) and blackish in colour, live beneath stones in rapidly flowing streams. These larvae have strong biting mouthparts and are ferocious predators on other aquatic insects and small invertebrates. They can also inflict painful bites on humans. Mature larvae migrate from their freshwater habitat to wet soil, moss, or decaying vegetation near the water to form pupal cells from which adults emerge. The larvae, sometimes known as hellgrammites, or toebiters, are eaten by fish, especially bass, and are used as bait by fishermen. Megaloptera larvae also act as important environmental indicators due to their high intolerance of water pollution.

Dobuni, also spelled DOBUNNI, an ancient British tribe centred on the confluence of the Severn and Avon rivers. The Dobuni, who were ruled by a Belgic aristocracy, apparently made peace with the Roman emperor Claudius (reigned AD 41–54). Later, Corinium (Cirencester) was made the capital, and it soon became the second largest city in Britain. The Dobuni economy was based primarily on beef and wool, and the tribe's prosperity is attested by the remains of numerous villas in the vicinity.

Doby, Larry, byname of LAWRENCE EUGENE DOBY (b. Dec. 13, 1923, Camden, S.C., U.S.—d. June 18, 2003, Montclair, N.J.), American baseball player, the second African American player in the major leagues and the first in the American League when he joined the Cleveland Indians in 1947.

He played for the Newark Eagles of the Negro National League (1942–43, 1946–47) before signing with the Indians. He played centre field for the Indians, who won the World Series in 1948 and a pennant in 1954. Doby was an all-star for 7 of his 13 major-league seasons (1947–59), which included time with the Chicago White Sox and the Detroit Tigers. In 1962 he played in Japan with the Chunichi Dragons. He became the second African American major league manager when he was hired by the White Sox in 1978. He was elected to the Baseball Hall of Fame in 1998.

doby mouth (animal disease): see sore mouth.

Dobzhansky, Theodosius, original name FEODOSY GRIGOREVICH DOBRZHANSKY (b. Jan. 25, 1900, Nemirov, Ukraine, Russian Empire [now in Ukraine]—d. Dec. 18, 1975, Davis, Calif., U.S.), Ukrainian-American ge-

neticist and evolutionist whose work had a major influence on 20th-century thought and research on genetics and evolutionary theory.

The son of a mathematics teacher, Dobzhansky attended the University of Kiev (1917–21), where he remained to teach. In 1924 he moved to Leningrad (now St. Petersburg).

Dobzhansky

By courtesy of The Rockefeller University, New York

In 1927 Dobzhansky went to Columbia University in New York City as a Rockefeller Fellow to work with the geneticist Thomas Hunt Morgan. He accompanied Morgan to the California Institute of Technology in Pasadena and, on being offered a teaching position there, decided to remain in the United States, becoming a citizen in 1937. He returned to Columbia as a professor of zoology in 1940, remaining until 1962, and then moved to Rockefeller Institute (later Rockefeller University). After his official retirement, Dobzhansky went in 1971 to the University of California at Davis.

Between 1920 and 1935, mathematicians and experimentalists began laying the groundwork for a theory combining Darwinian evolution and Mendelian genetics. Dobzhansky was involved in the project almost from its inception. His book *Genetics and the Origin of Species* (1937) was the first substantial synthesis of the subjects and established evolutionary genetics as an independent discipline. Until the 1930s, the commonly held view was that natural selection produced something close to the best of all possible worlds and that changes would be rare and slow and not apparent over one life span, in agreement with the observed constancy of species over historical time.

Dobzhansky's most important contribution was to change this view. In observing wild populations of the vinegar fly *Drosophila pseudoobscura*, he found extensive genetic variability. Furthermore, about 1940 evidence accumulated that in a given local population some genes would regularly change in frequency with the seasons of the year. For example, a certain gene might appear in 40 percent of all individuals in the population in the spring, increase to 60 percent by late summer at the expense of other genes at the same locus, and return to 40 percent in overwintering flies. Compared to a generation time of about one month, these changes were rapid and effected very large differences in reproductive fitness of the various types under different climatic conditions. Other experiments showed that, in fact, flies of mixed genetic makeup (heterozygotes) were superior in survival and fertility to pure types.

It was already known that these superiorities of such heterozygotes would ensure the preservation of both sets of genes in the population. Dobzhansky pointed out that newly arisen genes are rare at first and that an individual is exceedingly unlikely to receive such a gene from both parents. Hence, in the begin-

ning, the only genes that can "get ahead" and become more widespread in the population are those that are "good mixers"—that is, those that produce superior genotypes when combined with a random gene from the population.

A genetic system of the kind proposed by Dobzhansky can change rapidly, in response to natural selection, if environmental conditions should change. Among the myriad genotypes appearing in each generation would be many that were adapted to the changed conditions and that would leave more descendants; thus, these genes would be more common in the next generation. In contrast, under the older idea of a fairly uniform population in which most gene variants occurred rarely, much more time would be needed before variants adapted to new conditions could arise and become common. Meanwhile, local populations of the species could be in danger of becoming very reduced in numbers or even extinct.

Other important work of Dobzhansky dealt with speciation: the process by which a species does not merely change its characteristics over time but actually splits into two or more species. In extension of his work in human genetics and in human paleontology, Dobzhansky also wrote on the "descent of man" in *Mankind Evolving* (1962). Finally, his interest in the direction that human evolution might take in the future, added to a natural philosophical inclination, led him into thought on the nature of humans and the purpose of life and death, as shown in his works *The Biological Basis of Human Freedom* (1956) and *The Biology of Ultimate Concern* (1967). *Genetics of the Evolutionary Process* (1970) reflects 33 years of scientific progress in the study of evolution, largely by Dobzhansky or under his influence.

Dobzhansky provided an important part of the factual evidence for modern evolutionary theory. His preeminence, however, lay even more in the rare talent for synthesizing the masses of experimental and theoretical data in the literature into a broad, comprehensive view of the subject.

BIBLIOGRAPHY. Mark B. Adams (ed.), *The Evolution of Theodosius Dobzhansky: Essays on His Life and Thought in Russia and America* (1994).

Doccia porcelain, porcelain produced at a factory near Florence founded by Marchese Carlo Ginori in 1735; until 1896 the enterprise operated under the name Doccia, since then under the name Richard-Ginori. After an initial experimental period, during which he imported Chinese porcelain samples, Ginori engaged two Viennese painters, J.C.W. Anreiter and his son Anton, with Gaspare Bruschi employed as chief modeler. By 1740 Doccia had a monopoly of porcelain making in Tuscany and in 1746 began public sales. The product was a grayish, hard-paste porcelain made from local clay, with a glaze lacking in brilliance; a finer, white paste was adopted later. Early wares were decorated by stencil, a rare process that was to give way to a fine range of painted colours.

Such early Doccia porcelain, hardly ever marked, is often credited to other factories. In the main, Doccia continued, belated by some 30 years, the late Baroque styles of Meissen. Three decorative themes distinguish this Doccia ware: the *a galletto* design, of Chinese origin, consisting of two fighting cocks; the *a tulipano* pattern, a central, stylized red tulip with surrounding flowers; and a range of polychrome or white-figured reliefs of mythological subjects often erroneously named Capodimonte and introduced during the highly successful directorship of Lorenzo Ginori (1757–91). Doccia figures (some of which are very large) include Meissen-like figurines and Oriental figures, peasant and rustic groups, and versions of Baroque sculpture in both single figures and groups. Virtually the only Ital-

ian porcelain factory to prosper in the 19th century, Doccia extended its production to porcelain for industrial use. In recent times modern ware has been complemented by the reintroduction of traditional patterns.

Doce River, Portuguese RIO DOCE, river, eastern Brazil, formed by the junction of the Carmo and Piranga rivers in southeastern Minas Gerais state. Flowing northeastward to Governador Valadares, southeastward to Colatina, and thence eastward across the coastal plain of Espírito Santo state, it empties into the Atlantic Ocean near Regência after a course of approximately 360 miles (580 km). It is the only water-level route by land to Brazil's interior from the eastern shore. The swamps and lagoons of the lower Doce have given rise to large sanitation works. Its upper course is commercially important because the mineral riches of Minas Gerais are funneled out via the railroad paralleling the river.

Docetism (from Greek *dokein*, "to seem"), Christian heresy and one of the earliest Christian sectarian doctrines, affirming that Christ did not have a real or natural body during his life on earth but only an apparent or phantom one. Though its incipient forms are alluded to in the New Testament, such as in the Letters of John (e.g., 1 John 4:1–3; 2 John 7), Docetism became more fully developed as an important doctrinal position of Gnosticism, a religious dualist system of belief arising in the 2nd century AD which held that matter was evil and the spirit good and claimed that salvation was attained only through esoteric knowledge, or gnosis. The heresy developed from speculations about the imperfection or essential impurity of matter. More thoroughgoing Docetists asserted that Christ was born without any participation of matter and that all the acts and sufferings of his life, including the Crucifixion, were mere appearances. They consequently denied Christ's Resurrection and Ascension into heaven. Milder Docetists attributed to Christ an ethereal and heavenly body but disagreed on the degree to which it shared the real actions and sufferings of Christ. Docetism was attacked by all opponents of Gnosticism, especially by Bishop Ignatius of Antioch in the 2nd century.

dock, artificially enclosed basin into which vessels are brought for inspection and repair.

A brief treatment of docks follows. For full treatment, see MACROPAEDIA: Public Works: Harbours and sea works.

Originally, docks were used for many purposes: as dry basins, isolated from the water by dikes or other means, they served as a place for building and repairing ships (dry docks, *q.v.*); as wet basins, open to the water, they provided berthing space for ships in the normal course of traffic and cargo transfer. The latter function was later rendered by another group

Harbour installation on a tidal river, showing dock cargo handling and dry dock facilities

Encyclopaedia Britannica, Inc.

of structures especially designed for that purpose and given different designations such as quay wall, pier, and wharf. The term dock is still often used in a generic sense to indicate all waterfront docking facilities, either dry basin or berthing structures.

Docks used as berthing structures include quay walls, wharves, piers, and floating pontoon docks. Perhaps the oldest and most common waterfront facility for vessels, the quay wall is simply a retaining wall along the shore topped with a deck or platform, serving both as a barrier to protect the shore and as a staging area for cargo and passengers. Usually earth is placed behind the wall in order to build up the deck to the needed height above the prevailing high water level. In addition, it may be necessary to do some dredging in front of the wall to obtain the required water depth.

At locations where the conformation of the shore and depth of water do not favour economical construction of a quay wall, a wharf, consisting of a trestle-mounted rectangular platform running parallel to the shoreline, and with a connecting passageway to the shore, may be constructed. Normally only the front or seaward side of a wharf is used for berthing, because the water depth and accessibility on the other three sides may not be suitable for many vessels.

Because quay walls occupy valuable waterfront space, docking cost at a quay wall is high. A more economical expedient is the pier, which in its simplest form is merely a platform extending over the water, usually at right angles to the shoreline. Vessels can be moored to the pier, which serves as a transfer platform for cargo and passengers. A pier is composed of two main parts: the deck and its supporting system. The deck is usually built of reinforced concrete, though timber may be used. The supporting system is an assembly of beams, girders, and bearing piles, framed together to form a series of bents or trestles.

Floating pontoon docks, of which few have been built, rise and fall with the water level. One such dock floats up or down guided by walls of sheet-steel piling driven to bedrock, which serves to anchor or moor the whole assemblage. Access to shore is provided by a trestle hinged at the shore end and resting freely on the pontoon at the other end.

Dock, Christopher (b. 1698?, Germany—d. 1771, Skippack, Montgomery county, Pa. [U.S.]), Mennonite schoolmaster in colonial Pennsylvania whose teaching methods gave rise to publication of the first known book dealing with education in America.

Pious and humble, Dock in 1750 reluctantly wrote a description of his teaching methods. Originally intended for posthumous publication, his manuscript, *Schulordnung* ("School Management"), was published in 1770, a year before his death. The volume proved very influential and went into a second edition the same year; it was republished as late as 1861.

Dock advocated gentleness and encouragement in the teacher-student relationship. He counseled that discipline should grow from love, and he encouraged teachers to be simple, direct, and understanding, rather than harsh and overbearing.

Docodon, extinct genus of primitive mammals known only from fossilized teeth found in European deposits of the Late Jurassic (*i.e.*, those 144 to 163 million years old). The dentition patterns of the cusps and other molar structures are complex and distinct. Although it is uncertain whether *Docodon* is related to any modern mammals, it has been suggested that the genus may be close to that of the monotremes, the modern platypus and spiny anteater.

doctorate, a type of academic degree. *See* degree.

Doctors' Commons, formerly a self-governing teaching body of practitioners of canon and civil law. Located in London, it was similar to the Inns of Court, where English common law, rather than civil law, was taught. Members of the Doctors' Commons were those who held degrees either of doctor of civil law at Oxford or doctor of law at Cambridge and who subsequently had been admitted as advocates (similar to admittance to the bar for common lawyers) by the dean of arches, the presiding officer of the Court of Appeal under the authority of the archbishop of Canterbury. Members of the governing body, called fellows, were elected from the advocates by existing fellows. The members practiced in the ecclesiastical courts and in the Court of Admiralty. They also participated in arbitrations involving questions of international law.

In 1565 the society leased a site in Paternoster Row, near St. Paul's, which served as its headquarters until 1858. In that year, the society was dissolved, under terms of the Court of Probate and Matrimonial Causes acts of 1857. These measures were forerunners of the Judicature Act of 1873, which established a single supreme court of the judicature that inherited the jurisdiction of the courts of civil law as well as those of common law and equity, with a single bar practicing before it. *See also* Inns of Court.

Doctors' Plot (1953), alleged conspiracy of prominent Soviet medical specialists to murder leading government and party officials; the prevailing opinion of many scholars outside the Soviet Union is that Joseph Stalin intended to use the resulting doctors' trial to launch a massive party purge.

On Jan. 13, 1953, the newspapers *Pravda* and *Izvestiya* announced that nine doctors, who had attended major Soviet leaders, had been arrested. They were charged with poisoning Andrey A. Zhdanov, Central Committee secretary, who had died in 1948, and Alexander S. Shcherbakov (d. 1945), who had been head of the Main Political Administration of the Soviet army, and with attempting to murder several marshals of the Soviet army. The doctors, at least six of whom were Jewish, also were accused of being in the employ of U.S. and British intelligence services, as well as of serving the interests of international Jewry. The Soviet press reported that all of the doctors had confessed their guilt.

The trial and the rumoured purge that was to follow did not occur because the death of Stalin (March 5, 1953) intervened. In April *Pravda* announced that a reexamination of the case showed the charges against the doctors to be false and their confessions to have been obtained by torture. The doctors (except for two who had died during the course of the investigation) were exonerated. In 1954 an official in the Ministry of State Security and some police officers were executed for their participation in fabricating the cases against the doctors.

In his secret speech at the 20th Party Congress (February 1956), Nikita S. Khrushchev asserted that Stalin had personally ordered that the cases be developed and confessions elicited, the "doctors' plot" then to signal the beginning of a new purge. Khrushchev revealed that Stalin had intended to include members of the Politburo in the list of victims of the planned purge.

Doctors Without Borders, French MÉDECINS SANS FRONTIÈRES, a privately funded, independent humanitarian group based in Paris and dedicated primarily to helping victims of political violence or natural disasters. Its members often faced personal danger. The group received the 1999 Nobel Prize for Peace.

The organization was founded in 1971 by 10 French physicians who disagreed with the Red Cross's neutrality position and decided not to wait for a government's invitation before ex-

tending help. It aided victims in disasters ranging from the 1972 earthquake in Nicaragua to the 1990s conflict between Russia and Chechnya. By the late 1990s doctors and other medical personnel from 45 nations were participating in Doctors Without Borders.

documentary film, motion picture that shapes and interprets factual material for purposes of education or entertainment. Documentaries have been made in one form or another in nearly every country and have contributed significantly to the development of realism in films. John Grierson, a Scottish educator who had studied mass communication

Scene from *Drifters* (1929), directed by John Grierson and produced by the British Film Board
By courtesy of the Museum of Modern Art Film Stills Archive, New York

in the United States, adapted the term in the mid-1920s from the French word *documentaire*. The documentary-style film, though, had been popular from the earliest days of filmmaking. In Russia, events of the Bolshevik ascent to power in 1917-18 were filmed, and the pictures were used as propaganda. In 1922 the American director Robert Flaherty presented *Nanook of the North*, a record of Eskimo life based on personal observation, which was the prototype of many documentary films. At about the same time, the British director H. Bruce Woolfe reconstructed battles of World War I in a series of compilation films, a type of documentary that bases an interpretation of history on factual news material. The German *Kulturfilme*, such as the feature-length film *Wege zu Kraft und Schönheit* (1925; *Ways to Health and Beauty*), were in international demand.

The British documentary film movement, led by Grierson, influenced world film production in the 1930s by such films as Grierson's *Drifters* (1929), a description of the British herring fleet, and *Night Mail* (1936), about the nightly mail train from London to Glasgow. The United States, too, made significant contributions to the genre. Early examples include two films directed by Pare Lorentz: *The Plow That Broke the Plains* (1936), set in America's dust bowl, and *The River* (1937), a discussion of flood control.

The production of documentaries was stimulated by World War II. The Nazi government of wartime Germany used the nationalized film industry to produce propaganda documentaries. The American director Frank Capra presented the *Why We Fight* (1942-45) series for the U.S. Army Signal Corps; Great Britain released *London Can Take It* (1940), *Target for Tonight* (1941), and *Desert Victory* (1943); and the National Film Board of Canada turned out educational films in the national interest.

In the early 1950s attention once again focused on the documentary in the British free cinema movement, led by a group of young filmmakers concerned with the individual and his everyday experience. Documentaries also became popular in television program-

ming, especially in the late 1960s and the early 1970s. *See also* cinéma vérité.

Documentary Theatre: *see* Fact, Theatre of.

Doda Betta, mountain peak, highest point in Tamil Nādu state, southeastern India, rising to an elevation of 8,652 feet (2,637 m) near Uthagamandalam (Ootacamund). Doda Betta is a grass-covered hill that is frequently climbed by summer visitors, and the summit is accessible by automobile. It is the second highest peak in the Western Ghāts.

dodder (genus *Cuscuta*), any leafless, twining, parasitic plant of the only genus of the family Scutellariaceae. The genus contains more than 150 twining species that are widely distributed throughout the temperate and tropical regions of the world. Many species have been introduced with their host plants into new areas.

The dodder contains no chlorophyll and instead absorbs food through haustoria; these are rootlike organs that penetrate the tissue of a host plant and may kill it. The slender, stringlike stems of the dodder may be yellow, orange, pink, or brown in colour. The dodder's flowers, in nodulelike clusters, are made up of tiny yellow or white bell-like, lobed corollas (united petals). Its leaves are reduced to minute scales. The Cuscutaceae family is so close to the morning glories that some authorities unite it with the family Convolvulaceae.

The dodder's seed germinates, forming an anchoring root, and then sends up a slender stem that grows in a spiral fashion until it reaches a host plant. It then twines around the stem of the host plant and throws out haustoria, which penetrate it. Water is drawn through the haustoria from the host plant's stem and xylem, and nutrients are drawn from its phloem. Meanwhile, the root of the

Dodder (*Cuscuta gronovii*)

Russ Kinne—Photo Researchers

dodder rots away after stem contact has been made with a host plant. As the dodder grows, it sends out new haustoria and establishes itself very firmly on the host plant. After growing in a few spirals around one host shoot, the dodder finds its way to another, and it continues to twine and branch until it resembles a fine, densely tangled web of thin stems enveloping the host plant.

Dodder can do great damage to crops of clover, alfalfa, flax, hops, and beans. It is mainly controlled by the hand removal of the plants from fields and by preventing the plant's accidental introduction.

Dodds, Alfred-Amédée (b. Feb. 6, 1842, Saint-Louis, Senegal—d. July 18, 1922, Paris,

Fr.), French military figure who played a leading role in French colonial expansion in West Africa in the late 19th century.

After training at the prestigious military academy of Saint-Cyr, Dodds joined the French marine force. A company commander in the Franco-German War, he was captured at the Battle of Sedan in 1870, only to escape and return to combat in the Loire campaign. After the war Dodds returned to West Africa, where, except for brief visits to Indochina (1878 and 1883), he spent the next 20 years. In 1892–93, he led the campaign against the native forces of King Behanzin of Dahomey. His victory at Abomey (1892) was vital to the eventual linkage of French possessions in upper Senegal and the upper Niger region.

In 1899 Dodds was appointed inspector general of the marine infantry and soon after was given command of the 20th (colonial) army corps. In 1904 he returned to Paris and served on the *conseil supérieur de guerre* (high command of war, an autonomous command group) until 1914.

Dodecanese, Modern Greek DHODHEKÁNISOS, group of islands in the Aegean Sea, off the southwestern coast of Turkey, and constituting the *nomós* (department) of Dhodhekánisos, Greece. The city of Rhodes is the administrative centre. The name Dodecanese means "12 islands." The term has been applied at various times to groups differently composed and numbering more than 12. The main islands of the Dodecanese group, with their Italian names in parentheses, are: Kárpáthos (Scarpanto), Pátmos (Patmo), Kásos (Caso), Astipálaia (Stampalia), Lipsoí (Lisso), Léros (Lero), Kálimnos (Calino), Nísiros (Nisiro), Tilos (Piscopi), Kháiki (Calchi), Sími (Simi), Rhodes (Rodi), and Cos (Coo) and the outlying Kastellórizon (Castelrosso). Their land area is 1,031 square miles (2,670 square km). (*See also* Astipálaia; Cos; Kálimnos; Kárpáthos; Kastellórizon; Léros; Pátmos; Rhodes.)

The islands' substantial economic deficit has been cut gradually by increasing tourism. Except for Rhodes and Cos, the Dodecanese suffer from deforestation and poor drainage. Their crops—fruit, tobacco, olives, and wheat—have varied from marginal to enough to export, and the principal nonagricultural occupations of the islanders—fishing, shipping, sponge diving—are still underdeveloped. The islands have benefited, however, from the remarkable development of tourism in the principal islands of the group.

The islands were a part of the ancient Greek world, and Rhodes and Cos have long histories. In neither the Hellenistic nor the Roman Empire periods did the islands function as a single political or geographic unit. In the Byzantine Empire the theme (province) of the Dodecanese included the Cyclades islands as well.

The Dodecanese group came to be fixed at 12 islands during the long Turkish administration of them, which began in the 16th century. The Turks recognized 12 of the islands, "the 12 Sporades," as being entitled to special treatment since they had voluntarily submitted to Turkish rule. But the larger and richer islands of Rhodes and Cos had submitted involuntarily to Turkish rule and were given no special privileges. Turkish rule of the islands lasted until May 1912, when during the Italo-Turkish War Italian forces seized the islands—except Ikaría (which was occupied by Greek forces in November) and Kastellórizon (which remained Turkish).

Secret treaties on the future of the islands, drawn up by the Allies during and after World War I, led to a dispute between Italy and Greece over which nation should have jurisdiction over the islands. In 1919 an agreement was reached whereby Italy would cede the Dodecanese to Greece with the exception of Rhodes, which was to have broad local

autonomy. Subsequent Italian governments, however, unilaterally denounced the accord with Greece and refused to carry it out, and Italy used a special article in the Treaty of Sevres (1920), whereby Turkey had ceded to Italy all rights and titles to the Dodecanese and Kastellórizon, to enforce its claim on the Dodecanese. Italian sovereignty over the islands was confirmed by the Treaty of Lausanne (1923).

Italian rule over the Dodecanese was firm and efficient but never popular. Italian became the official language, and in 1925 the Dodecaneseans were obliged to take Italian citizenship. As a result, considerable migration from the islands to the United States occurred. After World War II the islands temporarily came under British occupation, with Greek participation. The conference of foreign ministers in Paris agreed in 1946 that the islands should pass to Greece; they were formally ceded in 1947. Pop. (1991) 162,596.

Dodeigne, Eugène (b. July 27, 1923, Rouvieux, near Liège, Belg.), Belgian-born French sculptor best known for his monumental stone figures, usually placed outdoors.

Dodeigne was trained by his father, a stonemason, and attended the École des Beaux-Arts in Tourcoing and the Académie des Beaux-Arts in Paris. From the emaciated angularity of his earliest carved wooden figures he moved steadily toward a use of eroded curves and complete abstraction. In 1949 he settled in Bondues in northern France, where he began to sculpt in the local Soignies blue limestone. His works range widely in scale. While the smaller of his Soignies forms are highly polished, the surfaces of the monumental outdoor pieces (e.g., "Sculpture," 1958) are stressed and patterned, suggesting weathered traces of archaic decoration.

Doderer, Heimito von (b. Sept. 6, 1896, Weidlingau, near Vienna, Austria—d. Dec. 23, 1966, Vienna), Austrian novelist who achieved international fame with his novel of post-World War I Vienna, *Die Dämonen* (1956; *The Demons*), on which he had worked since 1931. It explores the society and mood of Vienna in 1926–27 in a many-layered web of detail and complex characters.

Doderer served as an officer in the Imperial Austrian Dragoons in World War I and was captured by the Russians, spending several years in Siberia working as a lumberjack before repatriation in 1920. He received a doctorate in history from the University of Vienna in 1925. An involved psychological thriller, *Ein Mord, den jeder begeht* (1938; *Every Man a Murderer*), and several other novels attracted little attention. In the 1930s Doderer was briefly a member of the then-outlawed National Socialist Party in Austria, which he described in a book of reminiscences, *Tangenten* (1964; "Tangents"). In World War II he was a Luftwaffe captain. *Die Strudlhofstiege* (1951; "The Strudlhof Stairs"), which covered the Vienna scene in 1910–11 and 1923–25, sets the stage for *Die Dämonen*, which was a success and established Doderer's reputation. *Die Wasserfälle von Slunj* (1963; *The Waterfalls of Slunj*) was the first novel in an intended tetralogy spanning life in Vienna from 1880 to 1960 and collectively entitled *Roman Nr. 7* ("Novel No. 7"). The second volume, *Der Grenzwald* ("The Frontier Forest"), unfinished, appeared posthumously in 1967.

Grundlagen und Funktion des Romans (1959; "Principles and Function of the Novel") describes the novel as he sees it. Doderer's style and ideas are traditional and formal and had little influence.

Dodge, Bernard Ogilvie (b. April 18, 1872, Mauston, Wis., U.S.—d. Aug. 9, 1960, New York, N.Y.), American botanist and pioneer researcher on heredity in fungi.

After completing high school (1892), Dodge

taught in district schools and eventually became a high school principal. At the age of 28 he resumed his formal education at the Milwaukee Normal School. He obtained a bachelor's degree from the University of Wisconsin, Madison, in 1909, where he was much influenced by R.A. Harper, an eminent botanist who was soon to become professor of botany at Columbia University. As a consequence, Dodge moved to New York City and entered Columbia in 1909, receiving his Ph.D. three years later.

In 1920, after eight years as an instructor at Columbia, Dodge accepted an appointment as plant pathologist in the U.S. Department of Agriculture, Washington, D.C. In 1928 he became plant pathologist at the New York Botanical Garden, a position he held until his retirement in 1947. Even after retirement, he continued his research there until shortly before his death.

Because of the long delay in finishing his formal education, Dodge was over 40 when his first paper on mycology was published, his last work appeared when he was 85, and he was already 55 when his major work on the genetics of *Neurospora* began. In 1920 he had discovered heterothallism in the ascomycetes (sac fungi), first in *Ascobolus* and then in *Neurospora*. His early papers demonstrated the excellent potential of *Neurospora* for genetic research, and later he was able to prove conclusively that this fungus obeys the basic laws of genetics. He worked out excellent techniques for the experimental manipulation of *Neurospora*, as well as other microorganisms, and his many basic discoveries of new phenomena set the stage for the development of the field of biochemical genetics. At the age of 71, Dodge published jointly with H.W. Rickett the highly influential book, *Diseases and Pests of Ornamental Plants*.

Dodge, Grace Hoadley (b. May 21, 1856, New York, N.Y., U.S.—d. Dec. 27, 1914, New York City), American philanthropist who helped form organizations for the welfare of working women in the United States.

A great-granddaughter of David L. Dodge, New York merchant and peace activist, and granddaughter of William E. Dodge, metals business executive (Phelps, Dodge & Company) and philanthropist, Grace Dodge donated about \$1,500,000 and years of leadership to her philanthropies. In 1880 she helped form the Kitchen Garden Association (later the Industrial Education Association) to foster manual and domestic training and industrial arts in the public schools. In 1887 she funded the New York College for the Training of Teachers, which became Teachers College in 1892 and subsequently a school of Columbia University.

In 1884 Dodge helped organize a club for working women that eventually developed into the Association of Working Girls' Societies, a group encompassing some 75 units by 1890. She served as president of that association until 1905, when she mediated the merger of two rival Young Women's Christian Association groups into the Young Women's Christian Association (YWCA) of the United States. She served as president of the YWCA board until her death nine years later.

Dodge also organized the New York Travelers' Aid Society in 1907—a group devoted to the protection of migrant and immigrant women, and in 1912 she led efforts to organize the National Travelers' Aid Society; she contributed as well to the growth of the international travelers' aid movement.

Dodge, Grenville Mellen (b. April 12, 1831, Danvers, Mass., U.S.—d. Jan. 3, 1916, Council Bluffs, Iowa), American civil engineer who was responsible for much of the railroad construction in the western and southwestern United States during the 19th century.

Educated at Durham (N.H.) Academy and

Norwich (Vt.) University, Dodge graduated as a military and civil engineer in 1851, just when railroad building was beginning in the United States on a large scale. During the American Civil War he was promoted rapidly to the rank of brigadier general of volunteers and provided valuable service in bridge and railroad construction. For example, he built a bridge 14 feet (4 m) high and 710 feet (216 m) long across the Chattahoochee River in only three days.

From 1866 to 1870 Dodge was chief engineer for construction of the Union Pacific Railroad. In 1873 he joined Jay Gould in railroad development in the Southwest and in the next 10 years helped build nearly 9,000 miles (14,500 km) of track in the United States.

Dodge, Horace E.; and Dodge, John F., in full HORACE ELGIN DODGE and JOHN FRANCIS DODGE (respectively b. May 17, 1868, Niles, Mich., U.S.—d. Dec. 10, 1920; b. Oct. 25, 1864, Niles, Mich., U.S.—d. Jan. 14, 1920, New York, N.Y.), American brothers, automobile manufacturers who invented one of the first all-steel cars in America.

Bicycles were the first vehicles produced by the Dodge brothers. In 1901 they opened a machine shop in Detroit, making stove parts and, later, auto parts. The Dodge Brothers Company in 1910 established a large auto-parts plant in Hamtramck, Mich. There the brothers made engines and other auto parts for the Ford Motor Company and for Olds Motor Works. In 1913 they began producing their own automobiles, and the first Dodge automobile appeared on Nov. 14, 1914. Horace Dodge was responsible for a number of manufacturing innovations, including an oven that could bake enamel onto steel auto bodies. By 1920, the year in which both brothers died, Dodge was one of the industry's largest companies. The Dodge concern was purchased by Chrysler Corporation in 1928 and remains a division of Chrysler.

Dodge, John V., in full JOHN VILAS DODGE (b. Sept. 25, 1909, Chicago, Ill., U.S.—d. April 23, 1991, Glenview, Ill.), American editor and publishing executive of the *Encyclopædia Britannica*.

A graduate of Northwestern University, Evanston, Ill. (1930), Dodge also studied at the University of Bordeaux, France (1930–31). During World War II he served with U.S. Army Intelligence. He joined *Encyclopædia Britannica, Inc.*, in 1938, was managing and, later, executive editor of all Britannica publications (1950–64), and was vice president of the international division when he retired in 1972. Consultant to the editors of the 20-volume *Encyclopædia Universalis* (Paris), he also helped to develop multivolume encyclopaedias in Japanese, Portuguese, and Spanish.

Dodge, Josephine Marshall Jewell, née JEWELL (b. Feb. 11, 1855, Hartford, Conn., U.S.—d. March 6, 1928, Cannes, France), American pioneer in the day-nursery movement.

In 1875 she was married to Arthur Murray Dodge (d. 1896), son of a New York philanthropist. By the 1880s day nurseries for the children of working mothers were few in number and attempted, in general, only to alleviate the immediate child-care needs of the mother. In 1888 Josephine Dodge founded the Jewell Day Nursery in New York City, hoping to show that the day nursery should have a broader goal—that of instilling middle-class values into working-class children. In 1893 she demonstrated a model nursery at the World's Columbian Exposition in Chicago; in 1895 she founded the Association of Day Nurseries in New York City. In 1898 Dodge founded and directed the National Federation of Day Nurseries, which grew to 700 affiliates within some 20 years.

Dodge was also a prominent antisuffragist. She formed the National Association Opposed to Woman Suffrage in 1911 and edited *Woman's Protest*, an antisuffrage newsletter.

Dodge, Mary Mapes, in full MARY ELIZABETH MAPES DODGE (b. Jan. 26, 1831, New York, N.Y., U.S.—d. Aug. 21, 1905, Oteora Park, N.Y.), American author of children's books and first editor of *St. Nicholas* magazine.

As the daughter of an inventor and scientist, Mary Mapes grew up surrounded by creative figures. At 20 she married William Dodge, a lawyer, and they had two sons. To maintain her independence after she was suddenly widowed seven years later, she started writing children's stories. Her first collection, *Irvington Stories* (1864), centred on the American colonial family. Its success prompted her publisher to request another. The following year Dodge's beloved classic, *Hans Brinker; or, The Silver Skates*, appeared. The tale of an impoverished Dutch boy whose determination enabled him to obtain help for his sick father went through more than 100 editions during the author's lifetime.

In 1873, in the midst of an economic depression, Dodge was asked to become editor of a new publishing venture, the children's magazine *St. Nicholas*. Its subsequent success stemmed from Dodge's high literary and moral standards. Her editorial excellence enabled *St. Nicholas* to attract such well-known contemporary writers as Mark Twain, Bret Harte, Lucretia Peabody Hale, Louisa May Alcott, Robert Louis Stevenson, and Rudyard Kipling.

Dodge, William E., in full WILLIAM EARL DODGE (b. Sept. 4, 1805, Hartford, Conn., U.S.—d. Feb. 9, 1883, New York, N.Y.), American merchant, cofounder of Phelps, Dodge & Company, which was one of the largest mining companies in the United States for more than a century.

Descended from early New England settlers, Dodge began his career in the dry-goods business. In 1833 he and his father-in-law, Anson Phelps, organized the firm of Phelps, Dodge & Company, a dealer in metals. The company soon established a prosperous trade throughout the United States and abroad, eventually becoming the largest American importer of metals. Dodge's extensive investments included timberland in Pennsylvania, Michigan, and elsewhere; a copper mine in Minnesota; an iron mine in New Jersey; and mills in Connecticut, New Jersey, and other states. Dodge also had interests in a number of railroads, several of which served his metals companies.

In 1882 the company purchased the Copper Queen mine in Arizona, which signaled its entry into the front ranks of American mining companies, although metals extraction did not become the firm's primary business until after Dodge's death.

Considered an energetic and conservative man, Dodge was noted for his civic activities and his efforts on behalf of religious and temperance societies. He also served one term as a member of the U.S. Congress (1866–67), where he was an outspoken advocate of moderate postwar Reconstruction policies.

Dodge City, city, seat (1873) of Ford county, southwestern Kansas, U.S., on the Arkansas River. Fort Dodge, 5 miles (8 km) east, was established in 1864 and named for Colonel Henry I. Dodge. Settled in 1872, Dodge City attained notoriety as a frontier town on the old Santa Fe Trail, the rendezvous of picturesque characters, the centre of freight lines, and headquarters of the cattle business. At the peak of the cattle drives, in 1884, herds totaling 8,000,000 head passed through from

Texas. Lawlessness and gunfights resulted in the establishment of Boot Hill Cemetery, and a succession of marshals and sheriffs, including Bat Masterson and Wyatt Earp, won fame

Historic Front Street, Dodge City, Kan.

in the annals of the West. The famous Front Street has been restored and is now a popular tourist attraction that generates much of the city's revenue. Beeson Museum exhibits many pioneer relics. The modern city has railroad shops, cattle feed yards, and farm implement plants and is the supply centre for a wheat, sorghum, and stock-raising area. The meridian separating Central from Mountain Time passes near Dodge City. It is the site of Dodge City Community College (1935). Inc. 1875. Pop. (2003 est.) 25,568.

Dodgson, Charles Lutwidge (novelist): see Carroll, Lewis.

Dodington, George Bubb, BARON MELCOMBE OF MELCOMBE-REGIS, original name (until 1717) **GEORGE BUBB** (b. 1691—d. July 28, 1762, Hammersmith, Middlesex, Eng.), English politician, a career office seeker who was the subject of a satirical engraving by William Hogarth, "Chairing the Members" (1758), and kept a diary (published 1784) that remains one of the best sources on British politics of his time.

Until he was raised to the peerage (1761), he represented one of the House of Commons constituencies controlled by his family and selected members for two or three others. After serving capably as envoy extraordinary to

Dodington, detail of an engraving
By courtesy of the trustees of the British Museum, photograph, J.R. Freeman & Co. Ltd.

Spain (1715–17), he held a succession of government sinecures. In 1744 he was appointed treasurer of the navy, but he wavered in his support of George II, periodically opting instead to back the prince of Wales. His political philosophy was summarized in his couplet: "Strive thy little bark to steer/With the tide, but near the shore." His most creditable action was a speech (Feb. 22, 1757) against the impending execution of Admiral John Byng

on a questionable charge of neglect of duty in battle. He died without legitimate issue, and his peerage became extinct.

dodo (*Raphus cucullatus*), extinct flightless bird of Mauritius, one of the three species that constituted the family Raphidae, usually placed with pigeons in the order Columbiformes but sometimes separated as an order (Raphiformes). The other two species, also found on islands of the Indian Ocean, were the solitaires (*R. solitarius* of Réunion and *Pezophaps solitaria* of Rodrigues). The birds were first seen by Portuguese sailors about 1507 and were exterminated by man and his introduced animals. The dodo was extinct by 1681, the Réunion solitaire by 1746, and the Rodrigues solitaire by about 1790.

The dodo, bigger than a turkey, weighed about 23 kg (about 50 pounds). It had blue-gray plumage, a big head, a 23-centimetre (9-inch) blackish bill with reddish sheath forming the hooked tip, small useless wings, stout yellow legs, and a tuft of curly feathers high on its rear end. The Réunion solitaire may have been a white version of the dodo. The brownish Rodrigues solitaire was taller and more

Restoration of a dodo (*Raphus cucullatus*)

slender, with smaller head, short bill lacking the heavy hook, and wings with knobs. All that remains of the dodo is a head and foot at Oxford, a foot in the British Museum, a head in Copenhagen, and skeletons, more or less complete, in various museums. Many bones of solitaires have also been preserved.

Dodoens, Rembert, Latin **REMBERTUS DODONAENS**, original name **REMBERT VAN JOENCKEMA** (b. June 29, 1516/17, Mechelen, Spanish Netherlands [now in Belgium]—d. March 10, 1585, Leiden, Neth.), Flemish physician and botanist whose *Stirpium historiae pemptades sex sive libri XXX* (1583) is considered one of the foremost botanical works of the late 16th century.

Dodoens received a medical degree from the University of Louvain in 1535 and composed works on cosmography and physiology before turning to botany with the brief treatise *De frugum historia* (1552). His *Cruydeboek* (1554), an extensive herbal, owes a great deal to the "German fathers of botany," especially Leonhard Fuchs; instead of arranging plants in alphabetical order, Dodoens grouped plants according to their properties and reciprocal affinities. Translated into French in 1557, it became a standard in England through Henry Lyte's English translation of 1578. *Pemptades* introduced new families, arranged plants into 26 groups, and added many original and borrowed illustrations. It was the basis of John Gerard's celebrated *Herball*. Dodoens served as physician to the Holy Roman emperor Maximilian II and his successor, Rudolph II. He joined the

faculty of medicine at Leiden University in 1582.

Dodoma, city, designated national capital of Tanzania since 1974 (pending complete transfer of official functions from Dar es-Salaam), eastern Africa, about 300 miles (480 km) inland (west) from the Indian Ocean. Situated at an elevation of 3,720 feet (1,135 m) in a sparsely populated agricultural region, it is a market centre for peanuts (groundnuts), castor beans, sunflower seeds, gum, corn (maize), rice, wheat, coffee, tea, tobacco, and sorghum. Coffee and sisal are cultivated in the northern part of the region, and cattle raising is important throughout the region. Dodoma is connected by air, road, and rail with Arusha, Dar es-Salaam, and Tanga. The relocation of the national capital from Dar es-Salaam to Dodoma began in the early 1980s and was scheduled to be completed in the early 21st century. The population is primarily agricultural and is engaged in small-scale farming carried on in immediate proximity to residential quarters. Most of Dodoma's inhabitants are of the Gogo, Sanawe, Rangi, and Burungi peoples. Industries produce wood and furniture, beverages, processed food, milled rice and flour, soap, and oil. Pop. (2002) 324,347.

Dodona, ancient sanctuary of the chief Greek god, Zeus, in Epirus, Greece; the ceremonies held there had many remarkable and unusual features. The earliest mention of it is in the *Iliad* (xvi, 234), where its priests are called the Selloi (or Helloi) and are described as "of unwashed feet, sleeping on the ground." The description suggests worshipers or servants of an earth goddess or of some chthonian power with whom they kept in continual contact, day and night. Homer (*Odyssey*, xiv, 327) was also the first to mention the oracle at Dodona. A tree (or trees) was reputed to give oracles, presumably through the rustling of its leaves and other sounds. Herodotus, but no earlier writer, mentions priestesses, whom he describes as the givers of the oracles, doubtless under some kind of inspiration from the god. A further peculiarity of Dodona was the "bronze," a large gong set vibrating at every breeze by a scourge held in the hand of a figure standing over it; the persistent ringing passed into a Greek proverbial phrase—*Khalkos Dodones* ("Brass of Dodona")—for a continuous talker who has nothing to say.

Dodsley, Robert (b. 1703, near Mansfield, Nottinghamshire, Eng.—d. Sept. 23, 1764, Durham, Durham), British author, London bookseller, publisher, playwright, and editor who was influential in mid-18th-century literary England and is associated with the publication of works by Samuel Johnson, Alexander Pope, Thomas Gray, and Oliver Goldsmith.

Apprenticed to a stocking weaver, Dodsley ran away and went into domestic service as a footman; during this period he published a poem, *Servitude* (1729), which was later reissued as *The Muse in Livery: or, the Footman's*

Dodsley, detail of an oil painting by Sir Joshua Reynolds, 1760; in Dulwich College Picture Gallery, London
By permission of the Governors of Dulwich College Picture Gallery

Miscellany (1732). His other early works included a satirical farce, *The Toy-Shop* (1735). Financed by his friends, who included Alexander Pope, he established himself as a publisher in 1735, publishing Johnson's poem *London* (1738) and suggesting and backing his *Dictionary of the English Language*.

Dodsley founded several literary periodicals, including *The Annual Register* (1758), edited by the political philosopher Edmund Burke. Dodsley himself edited two major collections: *A Select Collection of Old Plays* (1744) and *A Collection of Poems. By Several Hands* (1748). In 1758 his tragedy *Cleone* began a long run at London's Covent Garden (2,000 copies of its text sold on the day of publication); and in 1759 he fêted, leaving the conduct of his business to his brother James.

Doe, Samuel K(anyon) (b. May 6, 1950/51, Tuzon, Liberia—d. Sept. 9/10, 1990, Monrovia), soldier and Liberian head of state from 1980 to 1990.

Doe, a member of the Krahn (Wee) tribe, enlisted in the army at age 18. He rose through the ranks to become a master sergeant in 1979. Like other indigenous Liberians, Doe resented the privilege and power granted the Americo-Liberians, descendants of the freed American slaves who founded the colony of Liberia in 1822. In April 1980 Doe led an attack by a group of Krahn soldiers on the Liberian executive mansion, killing President William R. Tolbert. Later, 13 prominent Tolbert associates were summarily tried and executed.

After the coup Doe assumed the rank of general and established a People's Redemption Council (PRC) composed of himself and 14 other low-ranking officers to rule the country. Doe suspended the nation's constitution until 1984, when a new constitution was approved by referendum. In 1985 he won a presidential election that was denounced as fraudulent by some observers. Doe faced opposition both at home and abroad, where his regime was often described as corrupt and brutal. His term of office was burdened by deteriorating economic conditions, and his life was continually threatened by assassination attempts and plots, which he suppressed with considerable brutality. These actions, along with Doe's favouritism toward his own Krahn tribe, sparked a rebellion against him that began in eastern Liberia in late 1989. By July 1990 the rebel forces had advanced into the capital city of Monrovia, but Doe refused to yield power. As the civil war continued, he was captured and assassinated.

Does, Johan van der, also called JANUS DOUSA (b. Dec. 5, 1545, Noordwijk, Spanish Habsburg domain [now in The Netherlands]—d. Oct. 8, 1604, The Hague), Dutch statesman, *jonkheer* (squire) of Noordwijk, poet, and historian who commanded the citizens' resistance movement during the Spanish siege of Leiden (1573–74); he was also the first curator of the University of Leiden.

In recognition of his leadership during the siege, as well as his background as a humanist scholar at the universities of Louvain and Paris, van der Does was appointed curator of the university, which was founded in 1575 to commemorate the raising of the siege. While curator he wrote many poems and historical treatises. His most important historical work was *Annales rerum a priscis Hollandiae comitibus per CCCXLVI annos gestarum* ("Annals of the Affairs of the Noble Counts of Holland Through 346 Years"), the first critical history of the province of Holland. This work first appeared in poetic form (1599) and later in prose (1601) as *Bataviae Hollandiaeque Annales* ("Annals of Batavia and Holland"). His poems include *Nova poemata* (1575; "New Poems").

Van der Does led a delegation (1584–85) that unsuccessfully offered sovereignty of the Netherlands to Queen Elizabeth I of England.

He also served as legal adviser to the Supreme Court (Hoge Raad) of Holland from 1591.

Doesburg, Theo van, pseudonym of CHRISTIAN EMIL MARIE KÜPPER (b. Aug. 30, 1883, Utrecht, Neth.—d. March 7, 1931, Davos, Switz.), Dutch painter, decorator, poet, and art theorist, a leader of the de Stijl movement.

Originally he intended to follow a career in the theatre, but he turned to painting about 1900 and worked in Post-Impressionist and Fauvist styles until 1916, when he began to paint geometric abstractions of subjects from nature. In 1917 he was instrumental in founding the de Stijl group and founded the avant-garde art review *De Stijl* (a publication that was continued until 1931). His advocacy of de Stijl's geometric style influenced the modernist architects Le Corbusier, Walter Gropius, and Ludwig Mies van der Rohe. From 1921 to 1923, when he taught at the Weimar Bauhaus, Doesburg's painting style was much influenced by Piet Mondrian's aesthetic of neoplasticism. Using the alias I.K. Bonset, he exhibited as a Dadaist in Holland in 1923 and published another art review, *Mechano*. In 1926 he wrote his manifesto "De Stijl," explaining his theory of elementarism, an aesthetic concept based on the use of inclined planes in geometric abstract paintings to increase the dynamic effect of the composition.

dog (species *Canis familiaris*), common mammal of the family Canidae (order Carnivora); it is related to wolves, foxes, and jackals.

A brief treatment of dogs follows. For full treatment, see MACROPAEDIA: Dogs.

Dogs are the first animal to have been domesticated. They probably originated somewhere in Eurasia approximately 12,000 to 14,000 years ago. The association may have developed gradually as wild dogs took to hanging around encampments to pilfer scraps, and humans began to rely on the dogs for warning of any approaching danger. Through the centuries many breeds were developed for specific tasks, such as hunting, herding, or guarding. Today, however, most dogs are kept chiefly for companionship.

Selective breeding by humans has had great effect on the natural variation present in one species. The smallest dog, the chihuahua, may weigh less than 2 pounds (0.9 kg), while 150 pounds (68 kg) is not uncommon for a mastiff or a Saint Bernard. Selective breeding has also altered the physical form of many breeds of dog. Early in domestication a mutation occurred for the upcurved tail; this trait occurs in most dog populations, but it is not found among wolves. Other variations from the original wolflike body-form include the very short legs of breeds such as dachshunds and Welsh corgis; the foreshortened face of bulldogs, mastiffs, and Pekingese; and the drooping ears that are more typical of domestic dogs than are the ancestral erect ears still found on some of the most wolflike breeds, such as German shepherds and malamutes. Coat colour also has been modified and includes solid black, black and tan, piebald (mottled), and white. Coat texture may be wolflike (as in German shepherds), curly (poodles), wiry (Airedale terriers), long (briards), short (Labrador retrievers), or even nonexistent (Mexican hairless).

Selective breeding has also enhanced particular behavioral patterns. Hounds, such as bloodhounds, foxhounds, and beagles, have been developed to hunt by scent; bloodhounds can follow a faint trail that is days old. The herding instinct, part of the hunting behaviour of the wolf and wild dog, has been highly developed in such breeds as border collies (used by shepherds) and Welsh corgis (used by cowherds). Some breeds, including the Great Pyrenees and komondors, live with flocks of sheep and protect them from predators. Terriers, such as fox terriers and miniature schnauzers, were developed to follow small game and vermin—such as foxes and rats—into their

burrows and to trap and kill them. Sporting breeds are used to find game birds—setters and pointers to stand on point (*i.e.*, stop and wait) when they locate a bird, spaniels to rush in and flush the bird, and retrievers to collect dead and wounded birds and bring them to the hunter. Mastiffs, originally used as guard dogs and watchdogs, have been superseded by more agile breeds, such as Doberman pinschers and German shepherds. Breeds like the husky, malamute, and Bernese mountain dog were developed mainly as draft animals. Members of all these breeds also serve as companions, as do the various toy or miniature dogs and breeds that are categorized as non-sporting dogs—*e.g.*, the Lhasa apso (originally a temple dog), the poodle (bred as a water retriever), and the Dalmatian (originally a hunting dog and later used to escort and guard horse-drawn carriages).

The dog's best-developed senses are smell and hearing. Its nasal passages can process large amounts of air, and the olfactory centre in the brain is enlarged. The dog's hearing is also acute; it can respond to frequencies of up to 35,000 vibrations per second (human hearing stops at 20,000). Sight is relatively poorly developed, although certain hounds (*e.g.*, greyhounds and Afghans), known as gazehounds, or sight hounds, have been bred to follow their prey—usually antelopes or hares—visually. All dogs lack colour vision.

Wild dogs are highly social animals and, like wolves, tend to run in groups and follow a leader. In domestic dogs, this characteristic makes possible the transference of "pack" loyalties to human owners. They are also fairly intelligent animals, and, when motivated, many can learn a large number of commands. German shepherds, Labrador retrievers, and poodles are among the most amenable to extended training, although individuals of almost any breed may excel in obedience.

Domestic dogs are mature by about one year of age, and females, called bitches, may come into their first heat, or estrus, before six months of age. Most bitches have two heats yearly, about six months apart. To avoid unwanted puppies, females can be spayed (removing the ovaries) and males castrated. After mating, dogs are attached in a copulatory tie for up to half an hour. Gestation lasts approximately nine weeks. An average litter consists of 4 to 6 puppies—born blind, deaf, and helpless—but the tiny breeds may have only 1 or 2 and the large breeds more than 10. Puppies should be allowed to nurse for at least six weeks before they are weaned. Between six and eight weeks is the ideal age at which to transfer the pup's social allegiance from dogs to humans, but this usually can be accomplished any time up to 12 weeks. Puppies that interact only with other dogs for a longer period of time may never become fully adapted to humans.

Simple training may begin at six to eight weeks, but complex training generally is not successful until the dog is about six months old. The reward system seems to be the best basis for training a dog; most work willingly for a pat and a fond word.

Various competitions are held by groups interested in dogs and dog breeding. During dog shows animals are judged on how closely they match the breed standards set by the ruling organization. In the United States these rules are formulated by the American Kennel Club, in Britain by the Kennel Club of England. Other competitions include field trials (for hunting and shepherd dogs) and obedience trials.

dog days, periods of exceptionally hot and humid weather that often occur in July, August, and early September in the northern temperate latitudes. The name originated with the ancient Greeks, Romans, and Egyptians;

they believed that Sirius, the dog star, which rises simultaneously with the Sun during this time of the year, added its heat to the Sun's and thereby caused the hot weather. Their belief that dogs were subject to spells of madness at this time also may have contributed to the name. Because people tended to become listless during the dog days, Sirius was held to have a detrimental effect on human activities.

dog lichen (species *Peltigera canina*), foliose (leafy) lichen usually found in patches 5 to 10 cm (2 to 4 inches) in diameter on heaths, sand dunes, walls, or grassy ground. The dull

Dog lichen (*Peltigera canina*)
Louise K. Broman—Root Resources

brown thallus with rounded lobes is soft when moist and papery when dry. Because its reproductive bodies resemble the teeth of a dog, it was used as a treatment for rabies in the European Middle Ages; powdered *Peltigera* was mixed with black pepper and warm milk.

dog racing, also called GREYHOUND RACING, the racing of greyhounds around an enclosed track in pursuit of an electrically controlled and propelled mechanical hare (rabbit). Dog racing is a 20th-century outgrowth of the older sport of coursing (*q.v.*), in which dogs hunted by sight rather than scent.

O.P. Smith demonstrated dog racing in 1919 at Emeryville, Calif., and the first track opened there that year. The sport was introduced in England in 1926 and became more popular

Greyhounds racing on a track
By courtesy of the National Greyhound Racing Club Ltd

there than in the United States. Dog racing later spread to such other countries as Ireland, Belgium, and Mexico.

In England there are normally eight races to a meeting. The National Greyhound Racing Club (founded 1928), the governing body, established race distances for flat and hurdle races from 230 to 1,200 yards (210 to 1,100 m). Usually no more than six greyhounds run in a race, which is run on grass. Most races are held at night under lights.

In the United States, dog racing started in California, but the sport had spread as far east as Florida by the mid-1920s. By the 1990s dog racing was a popular pastime in many states. Dog racing in the United States is under the supervision of state commissions. Eight dogs compete in each race, and there may be 10 or 11 races to a program. Dog tracks in the United States are made of sand and loam and

are normally ¼ mile (400 m), most races being at ⅜ or ⅝ mile. Betting, an essential feature of dog racing in most countries, is by the pari-mutuel (totalizator) system.

dog show, competition in which purebred dogs are judged on the basis of their physical perfection, as determined by breed standards. Dog shows in the United States are held according to rules set up by the American Kennel Club; shows in Great Britain follow the rules of the Kennel Club of England.

The first English dog show was held in Newcastle in 1859, and a more ambitious one followed at Chelsea in 1863. The best known of English dog shows is Cruft's, which has been held annually in London since 1886.

The first formal dog show in the United States was held in 1877 and was sponsored by the Westminster Kennel Club. The annual shows sponsored by this kennel club, in New York City, and by the International Kennel Club, in Chicago, are two of the most important dog shows in the United States.

dog tooth: see canine tooth.

doge (Venetian Italian: "duke"), highest official of the republic of Venice for more than 1,000 years (from the 8th to the 18th century) and symbol of the sovereignty of the Venetian state. The title was also used relatively briefly in Genoa.

In Venice the office of doge (from Latin *dux*, "leader") originated when the city was nominally subject to the Byzantine Empire and became permanent in the mid-8th century. According to tradition, the first doge was Paolo Lucio Anafesto, elected in 697.

From the 8th to the 12th century the doge's power was extensive, but all attempts to make the office hereditary failed. From the 12th century the aristocracy placed strict limits on the doge. Newly developed constitutional bodies took over many of the functions of government, and the doge on taking office had to swear an oath that restricted his freedom of action. During the same period, the main characteristics of the office were fixed: the doge was chosen from among the ruling families of Venice and held office for life. By

the 15th century the office had assumed the character of prince subject to law. The last doge, Ludovico Manin, was deposed when Napoleon conquered northern Italy in 1797.

Among the most famous doges, capable of exerting considerable political influence because of personal ability, were Enrico Dandolo (doge, 1192–1205), who promoted the Fourth Crusade, and Francesco Foscari (doge, 1423–57), under whom Venice first undertook conquests on the Italian mainland.

The name doge was also given to the principal civil official of Genoa, the office being modeled on that of Venice and instituted in 1339 to help end disorders among factions in the city. From 1384 to 1515 the popular elements of Genoa controlled the office of doge except for brief periods of foreign domination. In 1528 the office was reinstated but restricted to aristocrats who held it for a term

of two years. This office, like that of Venice, ended with French control of the peninsula.

Dōgen, also called JŌYŌ DAISHI, or KIGEN DŌGEN (b. Jan. 19, 1200, Kyōto, Japan—d. Sept. 22, 1253, Kyōto), leading Japanese Buddhist during the Kamakura period (1192–1333), who introduced Zen to Japan in the form of the Sōtō school (Chinese: Ts'ao-tung). A creative personality, he combined meditative practice and philosophical speculation.

Dōgen was born into a family of the court nobility and was orphaned at the age of seven. He was ordained a monk at 13 and studied the holy scriptures of Buddhism on Mount Hiei, the centre of Tendai Buddhism, without, however, fully satisfying his spiritual aspirations. Between 1223 and 1227 he studied Zen meditation in China and gained enlightenment under the Zen master Ju-ching. Back in Japan again, he lived at various temples and worked for the spread of Zen practice. He spent his last years at Eihei Temple, which he founded northwest of Nagoya. His first literary work, *Fukan zazen gi* (1227; "General Teachings for the Promotion of Zazen"), contains a brief introduction to the Zen practice. He wrote a number of other instructive works as well. His chief work, *Shōbōgenzō* (1231–53; "Treasury of the True Dharma Eye"), containing 95 chapters and written over a period of more than 20 years, consists of his elaboration of Buddhist principles. Dōgen taught *shikan taza*, "zazen only," zazen signifying the Zen practice of meditation in the cross-legged (lotus) position. He stressed the identity of practice and enlightenment.

Doges' Palace, Italian PALAZZO DUCALE, official residence in Venice of the doges, who were the elected leaders of the former Venetian republic. The first palace was built in 814 and was burned by the populace in 976. It was reconstructed, damaged by a second fire, and begun in its present form in the early 14th century. In 1424 the completion of this Venetian Gothic-style palace was undertaken, and the two identical facades facing the Molo (steps) and the Piazzetta San Marco were extended. The Porta della Carta, the main gateway, was designed by Giovanni and Bartolomeo Bon (Buon) and begun in 1438. Severe fires later necessitated rebuilding parts of the palace and destroyed the frescoes of, among others, Il Pisanello and paintings by the Bellini family and Titian. Partly in replacement of these, important paintings (still in situ) were commissioned from such artists as Tintoretto and Paolo Veronese.

dogfish, any of several small sharks of the families Squalidae, Scyliorhinidae, and Triakidae. In North America, the name is also used for a freshwater fish, the bowfin (*q.v.*).

The spiny dogfishes of the family Squalidae possess a sharp spine in front of each of their two dorsal fins. The most widely known species is *Squalus acanthias*, called the spiny dogfish, spurdog, or skittle dog. It is abundant along northern Atlantic and Pacific coasts; a closely related, if not identical, form inhabits the southern half of the world. The spiny dogfish is gray, with white spots, and is about 60 to 120 cm (2 to 4 feet) long. Often found in dense schools, it preys on fishes and various invertebrates. It is often a nuisance, as it takes baits and damages fishing nets, but it is edible and also yields liver oil and is ground for fertilizer. Its dorsal fin spines are associated with small venom glands and can cause painful wounds.

The spotted dogfishes of the family Scyliorhinidae include the larger spotted dogfish, or nursehound (*Scyliorhinus stellaris*), which grows to about 150 cm long, and the lesser spotted dogfish (*S. cuniculus*), which is about 90 cm long. Both of these common, brown-spotted sharks are caught and sold as food.

The smooth hound, or smooth dogfish

Smooth dogfish (*Mustelus canis*)

George Whiteley—The National Audubon Society Collection/Photo Researchers

(*Mustelus canis*), is one of the best-known members of the family Triakidae. It is also one of the most common sharks on the American Atlantic coast. It is a slim shark, up to 150 cm long, and is grayish in colour. Like others of its family, it has small teeth, arranged in series, and lacks a well-developed lower tail lobe. It is a bottom dweller and preys on fish and crustaceans.

Dogger Bank, extensive isolated shoal in the North Sea, lying about 60 miles (100 km) off the northeastern coast of England. It rises 70 feet (20 m) higher than the surrounding sea floor, is 160 miles (260 km) long and 60 miles wide at the 120-foot (35-metre) level, and reaches its shallowest point (50 feet [15 m] below the sea surface) at its western end. The bank is a huge moraine that was deposited at the southern limit of the last glaciation. For centuries it has been a well-known fishing ground. The large amounts of food available to the fish result in the catch of sizable quantities of plaice, cod, haddock, turbot, dabs, and herring. The origin of the name is obscure, but the Dutch *dogger*, signifying a trawling vessel, was formerly applied to two-masted ships employed in North Sea fishing and, by extension, to their crews (doggermen) and the fish taken (doggerfish). The lines demarcating the international rights of Great Britain, The Netherlands, Germany, Denmark, and Norway to the North Sea intersect just north of the Dogger Bank; all but Norway have rights to the bank itself.

doggerel, a low, or trivial, form of verse, loosely constructed and often irregular, but effective because of its simple mnemonic rhyme and loping metre. It appears in most literatures and societies as a useful form for comedy and satire. It is characteristic of children's game rhymes from ancient times to the present and of most nursery rhymes.

One of the earliest uses of the word is found in the 14th century in the works of Geoffrey Chaucer, who applied the term "rym doggerel" to his "Tale of Sir Thopas," a burlesque of the long-winded medieval romance.

John Skelton, caught in the transition between Chaucer's medieval language and the beginning of the English Renaissance, wrote verse long considered to be almost doggerel. He defended himself in *Colin Clout*:

For though my rhyme be ragged,
Tauered and jagged,
Rudely rain-beaten,
Rusty and moth-eaten,
If ye take well therewith,
It hath in it some piih.

Since then, doggerel has been employed in most English comic verse, from that of Samuel Butler and Jonathan Swift to the American poet Ogden Nash.

The German version, called *Knüttelvers* (literally "cudgel verse"), was popular during the Renaissance and was later used for comic effect by such poets as J.W. von Goethe and Friedrich von Schiller. Doggerel verse is still commonly heard in limericks and nonsense verse, popular songs, and commercial jingles.

Doggett, Thomas (b. c. 1670, Dublin, Ire.—d. September/October 1721, London, Eng.), English actor who excelled in low-comedy

parts and is best remembered as a member of a famous actor-manager triumvirate of Cibber, Doggett, and Wilks at the Drury Lane Theatre, London.

Doggett is said to have begun his acting career about 1691 in the provinces, appearing in London some years later. William Congreve so admired Doggett's acting that he wrote him the parts of Fondlewife in *The Old Batchelour* and Ben in *Love for Love*. For a while Doggett managed the Drury Lane Theatre with Colley Cibber and Robert Wilks, but the partnership broke up in a quarrel over politics. He wrote a comedy, *The Country Wake* (1696), that was successfully staged at Lincoln's Inn Fields Theatre and later revived by Cibber in 1711.

Doggett's Coat and Badge, one of the world's oldest continuing rowing races, held annually in England along the River Thames from London Bridge to Chelsea, a distance of 4 miles 5 furlongs (7.4 km). The race is a sculling contest between skiffs originally used to ferry passengers across the river. The boats are manned by watermen who have recently completed their apprenticeship. The contest was instituted in 1715 by Thomas Doggett, an English comic actor, to commemorate the accession of George I in 1714. Doggett provided for a cash prize and "an Orange coloured Livery with a Badge representing Liberty" to be awarded to the winner. Although the colour of the uniform has changed from orange to red and the cash prize is no longer awarded, Doggett's decree continues to be fulfilled.

Dogon, ethnic group of the central plateau region of Mali. There is some doubt as to the correct classification of the many dialects of the Dogon language; the Dogon language has been placed in the Mande, Voltaic, and other language groups. The Dogon number about 350,000, and the majority of them live in the rocky hills, mountains, and plateaus of the Bandiagara district. They are mainly an agricultural people; and their few craftsmen, largely metalworkers and leatherworkers, form distinct castes. They have no centralized system of government but live in villages composed of patrilineages and extended families, whose head is the senior male descendant of the common ancestor. Polygyny is practiced but reportedly has a low incidence.

Each large district has a *hogon*, or spiritual leader; and there is a supreme *hogon* for the whole country. In his dress and behaviour the *hogon* symbolizes the Dogon myth of creation, to which the Dogon relate much of their social organization and culture. Their metaphysical system—which categorizes physical objects, personifies good and evil, and defines the spiritual principles of the Dogon personality—is more abstract than that of most other African peoples. The climax of Dogon religious life occurs every 60 years, in a ceremony called the *sigui*. It occurs when the star Sirius appears between two mountain peaks. Before the ceremony, young men go into seclusion for three months, during which they talk in secret language. The general ceremony rests on the belief that some 3,000 years ago amphibious beings from Sirius visited the Dogon.

Fewer than half the Dogon are Muslim, and fewer still are Christian. Most practice traditional religion.

Dogra DYNASTY, Rājput clan, or group of clans, that still dominates the Indian state of Jammu and Kashmir. They form the chief, or *miān*, portion of Rājputs of the Jammu territory (lying north of Lahore, roughly between the Chenāb and Rāvi rivers). They are a hardy and martial people who attained prominence in the 19th century. There had long been a small state of Jammu, but after 1780 it became tributary to the Sikhs. One of the princely house, Gulab Singh, distinguished himself in the service of the Sikhs and was made raja of Jammu in 1820, which was the beginning of the Dogra dynasty. He expanded to the north, annexing Ladāk and Baltistān.

In the First Sikh War (1845–46), Singh held aloof and then appeared as a mediator. As a reward, Kashmir (annexed by the Sikhs in 1819) was given to him by the British for a cash payment. This was the origin of what became known as the Kashmir problem. Kashmir itself, apart from a Brahman minority, was Muslim in population, so that a Hindu thus ruled a Muslim majority state. In 1947 Hari Singh, the great-grandson of Gulab Singh, faced with an incursion of Pashtuns from Pakistan, acceded to union with India.

Dogrib, also called THLINGCHADINNE, a group of Athabaskan-speaking Indian tribes inhabiting the forested and barren-ground areas between the Great Bear and Great Slave lakes in northwestern Canada. The name is an English adaptation of their own name, Thlingchadinne, or Dog-flank People, referring to their fabled descent from a supernatural dog-man.

Traditionally, the Dogrib fished and hunted, subsisting chiefly on barren-ground caribou, which were trapped or speared. Their usual habitation was a skin-covered tepee, although in the hard winters they sometimes built wooden and brush-covered lodges. Their social organization consisted of many independent, loosely led bands, each with its own territory. Dogrib women enjoyed generally better status than those of other northern tribes (compare Chipewyan), but the aged and infirm were often cast off to die. The chief enemies of the Dogrib were the Cree, Chipewyan, and Yellowknife; the Yellowknife they eventually massacred in raids in the late 18th and early 19th centuries.

The Dogrib remained relatively isolated until the mid-20th century, when improved transportation and communication facilities brought them into greater contact with other parts of Canada. In the late 20th century the Dogrib numbered about 1,200.

dogsled racing, also called SLED DOG RACING, sport of racing sleds pulled by sled dogs over snow-covered cross-country courses; it was developed from a principal Eskimo method of transportation. Dogsleds are still used for transportation and working purposes in some northern areas, although they largely have been replaced by aircraft and snowmobiles.

The modern, lightweight racing sled weighs about 30 pounds (13.5 kg). Its ash frame is lashed together with leather and its runners sheathed with steel or aluminum. Dogs usually are especially bred and trained Eskimo dogs, Siberian huskies, Samoyeds, or Alaskan Malamutes. The teams typically consist of 4 to 10 dogs, with more being used for longer races. They are driven in pairs in a gang hitch. Control of the team is by voice, although drivers may carry whips of limited length. In open country, point-to-point races are held. In more populated areas, back roads form the course, with races usually varying in length from 12 to 30 miles (19 to 48 km). A team of 6 to 8 dogs can pull the sled and its driver, called a musher, at speeds of more than 20

miles (32 km) per hour. Teams start at intervals and race for time. Usually, all dogs must finish in the order they start, and an injured dog must be carried on the sled.

A dogsled-racing event was included in the 1932 Winter Olympics program and won by E. Goddard of Canada. The sport is popular in Norway, Canada, Alaska, and the northern states of the contiguous United States. One

Dogsled team racing in the Redstone Classic, Redstone, Colo.
Kent & Donna Dannen

popular event is the Iditarod Trail Sled Dog Race (*q.v.*) held in March between Anchorage and Nome, Alaska. A world-championship event is held annually at Laconia, N.H.

dogū, abstract clay figurines, generally of pregnant females, made in Japan during the Jōmon period (*c.* 5th or 4th millennium to *c.* 250 BC). *Dogū* are reminiscent of the rigidly frontal fertility figures produced by other prehistoric cultures.

Harelipped clay *dogū* figurine, mid-Jōmon period; in the Tokyo National Museum
By courtesy of the Tokyo National Museum

Their precise function is unknown, but archaeological evidence suggests they were aids in childbirth as well as fertility symbols. They are also found in simulated burials, indicating some kind of ceremonial function. Fired at a low temperature, they often have crumbly surfaces; many are painted in red.

Doğubayazıt, town, eastern Turkey, at an elevation of 6,000 feet (1,800 m) and situated about 10 miles (16 km) from Turkey's border with Iran. Lying near the ancient trade route from Trabzon (ancient Trebizond) to

İshak Paşa's palace, Doğubayazıt, Turkey
K Scholz—Shostal

northwestern Iran, Doğubayazıt was once an important trading town, but its importance declined with the reduction of trade along this route and was destroyed during the Russo-Turkish wars of the 19th century and World War I, when the town was occupied by Russian troops. On a spur above the town are cuneiform inscriptions dating from the 1st millennium BC. Now a transit station on the main Europe-Iran highway, Doğubayazıt is the trading centre for animal products of the region. Pop. (1990 prelim.) 35,488.

dogwood, any of the shrubs, trees, or herbs of the genus *Cornus*, in the dogwood family (Cornaceae), native to Europe, eastern

(Top) flowers and (bottom) leaves and fruit of flowering dogwood (*Cornus florida*)
J.C. Allen and Son

Asia, and North America. The bunchberry (*q.v.*; *C. canadensis*) is a creeping perennial herb. Flowering dogwood (*C. florida*), a North American species, is widely grown as an ornamental for its showy petallike bracts (modified leaves) under the tiny flowers. Cornelian cherry (*C. mas*), a European species also grown as an ornamental, produces fruit that is eaten fresh or made into preserves or wine (*vin de corneille*). The Pacific, or mountain, dogwood (*C. nuttallii*) resembles the flowering dogwood with minor differences. A few shrubby species are planted for their variegated leaves and colourful twigs—which can be red, purple, or yellow—and as food for game.

Since the mid-1970s a blight, dogwood anthracnose (*see* anthracnose), has infested the North American species, causing particularly severe damage in portions of the eastern United States.

Doha, Arabic AD-DAWĤAH, city, capital of Qatar, on the east coast of the Qatar Peninsula, in the Persian Gulf. About three-fifths of Qatar's population lives within the city's limits. Situated on a shallow bay, about 3 miles (5 km) from east to west, Doha (meaning "bay") has long been a locally important port. Because of offshore coral reefs and a shallow bottom, it handled only small vessels until the completion of its deepwater port in the 1970s.

The original quarter of the city, al-Bida', Bida in sailor's parlance, is at the northwest; it was probably founded by Sudanese refugees from the sheikhdom of Abu Dhabi. Long a centre of pirate activity in the Persian Gulf, Doha, then a small village, was destroyed in 1867 in the war between Bahrain (which was aided by Abu Dhabi) and Qatar. In the following year, the British government installed Muḥammad ibn Thāni Al Thāni, sheikh of Doha, as the

Quay in Doha, capital of Qatar
J Allan Cash

premier ruler of Qatar. He agreed to abide by the terms of the Perpetual Maritime Truce of 1853, and piracy was greatly reduced. In the late 19th century, the Ottoman Empire, as suzerain of much of the Arabian Peninsula, sporadically maintained a garrison at Doha. After Qatar became a British protected state in 1916, a British political agency was maintained in the town. In late 1971, Doha became the capital of newly independent Qatar.

Long a sleepy pearling and fishing village, Doha had about 350 pearling boats at the beginning of the 20th century. The development of Japanese cultured pearls and the worldwide economic depression of the 1930s severely affected the town. The development of Qatar's considerable oil reserves after World War II, however, led to a complete economic transformation. Qatar became an extremely prosperous country with a high per capita income and undertook the thorough modernization of its capital. Old slum sections were razed, and modern commercial and residential quarters were built; Doha's water supply is ob-

tained by distilling seawater. The deepwater port accommodates oceangoing vessels. The Qatar National Fishing Company, using modern motorized craft, is headquartered at the port, where a modern shrimp packing plant has been built. Sites of interest include the new Clock Tower Square, the souk (marketplace), and the new Government House (1969), built on reclaimed waterfront land. Doha International Airport is located just southeast of the city. Pop. (1997) 264,009.

Doherty, Laurie; and Doherty, Reggie, bynames of HUGH LAWRENCE DOHERTY and REGINALD FRANK DOHERTY (respectively b. Oct. 8, 1875, London, Eng.—d. Aug. 21, 1919, Broadstairs, Kent; b. Oct. 14, 1872, London, Eng.—d. Dec. 29, 1910), English tennis-playing brothers who dominated the sport from 1897 to 1906. As a team they held the record for the most doubles titles at Wimbledon, winning eight from 1897 to 1905.

Laurie held the Wimbledon record for most men's titles altogether, with 13 between 1897 and 1905, winning British singles from 1902 to 1906. Reggie took Wimbledon singles from 1897 to 1900. The Dohertys also won the U.S. doubles championships in 1902 and 1903, and Laurie was the first foreigner to win the U.S. singles, in 1903.

The brothers were vital to British Davis Cup competition from 1902 to 1906, during which time Laurie achieved the best record ever in Davis finals, going 7-0 in singles and 5-0 in doubles. Between 1902 and 1906 Reggie lost one singles match outright, to Malcolm Whitman of the United States in 1902, and one by default, to Bill Larned in 1903.

Doherty, Peter C. (b. Oct. 15, 1940, Australia), Australian immunologist and pathologist who, with Rolf Zinkernagel of Switzerland, received the Nobel Prize for Physiology or Medicine in 1996 for their discovery of how the body's immune system distinguishes virus-infected cells from normal cells.

Doherty earned bachelor's (1962) and master's (1966) degrees in veterinary medicine from the University of Queensland but switched to pathology while earning his Ph.D. (1970) from the University of Edinburgh, Scot. While conducting research (1972-75) at the John Curtin School of Medical Research in Canberra, Doherty began collaborating with Zinkernagel in studying what role the white blood cells known as T lymphocytes play in mice infected with a particular type of virus able to cause meningitis. They theorized that it was the strength of the immune response itself that caused the fatal destruction of brain cells in mice infected with this virus. To test this theory, they mixed virus-infected mouse cells with T lymphocytes from other infected mice. The T lymphocytes did destroy the virus-infected cells, but only if the infected cells and the lymphocytes came from a genetically identical strain of mice; the T lymphocytes would ignore virus-infected cells that had been taken from another strain of mice. Further research showed that T cells must recognize two separate signals on an infected cell before they will destroy it. One signal is a fragment of the invading virus that the cell displays on its surface; the other is a self-identifying tag from the cell's major histocompatibility complex (MHC) antigens, which identify a cell as belonging to one's own body. This concept of the simultaneous recognition of both self and foreign molecules formed the basis for a new understanding of the general mechanisms used by the immune system at the cellular level.

After teaching at the Wistar Institute in Philadelphia, Pa. (1975-82), Doherty headed the department of pathology at the Curtin School in Canberra (1982-88) and became chairman of the department of immunology at St. Jude Children's Research Hospital in Memphis, Tenn., in 1988.

Dohnányi, Ernst von, Hungarian ERNŐ DOHNÁNYI (b. July 27, 1877, Pozsony, Hung.—d. Feb. 9, 1960, New York, N.Y., U.S.), Hungarian composer, pianist, and conductor, principally known for his *Variations on a Nursery Song* for piano and orchestra.

Dohnányi, c. 1920
Jean-Loup Charmet—J.P. Zolo

Dohnányi studied in Budapest at the Royal Academy of Music, where his first symphony was performed in 1897. As a pianist he traveled widely and established a reputation as one of the best performers of his day.

He taught at the Berlin Academy for Music (1908-15) and was conductor of the Budapest Philharmonic and associate director of the Budapest Academy of Music (1919). In 1931 Dohnányi was musical director of Hungarian radio. In 1948 he left Hungary as a political exile; his influence under the prewar regime was held against him, and his music was banned in communist Hungary for more than 10 years. He taught in Argentina and from 1949 held the position of composer-in-residence at Florida State University. He became a U.S. citizen in 1955.

Dohnányi's music, which was chiefly influenced by Johannes Brahms, was late Romantic and conservative in style, and after 1910 he occupied only a minor place among contemporary Hungarian composers. His works include the *Ruralia Hungarica* for violin, three symphonies, a ballet, the *Suite in F-sharp Minor*, three operas, and chamber works, notably the *Second String Quartet* and the two piano and string quintets.

Doi Takako (b. Nov. 30, 1928, Kōbe, Japan), Japanese politician, educator, and head of the Japan Socialist Party (JSP; since 1991 called the Social Democratic Party of Japan [SDPJ]) from 1986 to 1991. She was the first woman ever to head a political party in Japan.

Doi attended Dōshisha University in Kyōto, and after her graduation she taught constitutional law there. She was elected to the House of Representatives (lower house of the Diet [parliament]) in 1969. After the JSP, second largest party in Japan's multiparty system, suffered a major defeat in the general elections of 1986, Doi was asked to lead the party. From the outset of her leadership she attempted to bring the party more into the mainstream on such divisive issues as defense and nuclear power.

Doi contributed to the growth in political power of Japanese women. Although she had done little to identify with feminist issues at the outset, she helped channel the dissatisfaction of women angered by the money politics and scandals of the ruling Liberal-Democratic Party (LDP). Following her "madonna strategy," a number of women candidates succeeded in winning office in the summer elections of 1989, and for the first time in three decades the LDP lost its majority of upper-house seats to the JSP under Doi's leadership.

Subsequent electoral reverses by her party, however, led to her resignation as party leader in June 1991, although she retained her lower-house seat. In August 1993, after the LDP had lost its majority in the lower house in

elections a month earlier and the SDPJ had joined in a coalition government, Doi became the first woman speaker of the House of Representatives.

Doisy, Edward Adelbert (b. Nov. 13, 1893, Hume, Ill., U.S.—d. Oct. 23, 1986, St. Louis, Mo.), American biochemist who shared the 1943 Nobel Prize for Physiology or Medicine with Henrik Dam for the discovery of the antihemorrhagic vitamin K (1939).

Doisy earned his bachelor's and master's degrees at the University of Illinois and his Ph.D. at Harvard University (1920). He taught at Washington University School of Medicine, St. Louis, Mo. (1919-23), and St. Louis University (1923-65; emeritus 1965-86). Over the years he worked with the embryologist Edgar Allen in developing assay techniques that facilitated research on sex hormones. Besides vitamin K itself, Doisy and his associates isolated a variant form of the vitamin, vitamin K₂, and the sex hormones estrone (theelin, 1929; the first estrogen to be crystallized), estriol (theolol, 1930), and estradiol (dihydrotheelin, 1935).

His writings include *Sex Hormones* (1936) and *Sex and Internal Secretions* (1939), with Edgar Allen and Charles H. Danforth.

Dokuchayev, Vasily Vasilyevich (b. Feb. 17 [March 1, New Style], 1846, Milyukovo, Russia—d. Oct. 26 [Nov. 8], 1903, St. Petersburg, Russia), Russian geomorphologist and early soil scientist.

In 1872 Dokuchayev became curator of geology at the University of St. Petersburg; in 1879 he joined the geology faculty and instituted the first course in Quaternary geology taught at a university. From 1892 to 1895 he reorganized and directed the Novo-Aleksandr Institute of Agriculture and Forestry, adding departments of soil science and plant physiology. He organized soil surveys throughout most of Russia and introduced the term *chernozem* to describe the black soil, rich in carbonates and humus, that occurs in the temperate latitudes of Russia. Dokuchayev viewed soil as the result of interaction between climate, bedrock, and organisms. In 1898 he introduced a classification of Russian soils that showed that similar bedrocks give rise to different soils, depending on climate. His emphasis on interactions among bedrock, climate, and organisms anticipated the biome theory.

Dōkyō (d. 772, Shimotsuke province [modern Tochigi prefecture], Japan), Japanese Buddhist priest who attempted to usurp the Japanese imperial throne.

In 761 Dōkyō won the confidence of the former empress Kōken (who had occupied the throne from 749 to 758) and, according to some accounts, became her lover. With the empress's aid he began to exercise a dominant influence within the government. In 764 Dōkyō succeeded in eliminating his major political rival, the minister Oshikatsu, who was the favorite of the emperor Junnin.

In the ensuing coup, the emperor was deposed, and the former empress reascended the throne, ruling as the empress Shōtoku (764-770). Within a year Dōkyō was named prime minister, and in 766 he also was made high priest of state. Not content with virtually ruling the country, he persuaded an oracle to predict his succession to the throne, a pretension that angered many important members of the government, especially those of the powerful Fujiwara family. When the empress died in 770, the Fujiwara had Dōkyō banished from the capital. As a result of this episode, no woman was allowed to succeed to the Japanese throne for nearly a thousand years.

dolce stil nuovo (Italian: "sweet new style"), nuovo also spelled NOVO, the style of a group

of 13th–14th-century Italian poets, mostly Florentines, whose vernacular sonnets, canzoni, and ballate celebrate a spiritual and idealized view of love and womanhood in a way that is sincere, delicate, and musical. The Bolognese poet Guido Guinizelli is considered a forerunner of the *stilnovisti* (“writers of the new style”), and the most brilliant poets of the group were Guido Cavalcanti and Dante himself (in his lyric works). The most prominent minor poet associated with the group was Cino da Pistoia; others were Lapo Gianni, Gianni Alfani, and Dino Frescobaldi.

Several influences prepared the way for the development of the *dolce stil nuovo*. Among these influences were the troubadour poetry of Provence, which contained a courtly love tradition and used poetic forms that evolved into the Italian sonnet and canzone; the simplicity and mysticism of St. Francis of Assisi and his followers; the 13th-century Sicilian school of poets, who created the sonnet and canzone from Provençal forms and who were the first poets in Italy to use the vernacular; and the philosophical doctrines of Thomism, Platonism, and Aristotelianism, with which all the *stilnovisti* had contact. Guinizelli’s contribution was his own gentle style of poetry as well as the exalted view of woman and love, which he presented in the canzone “Al cor gentil ripara sempre amore” (“Within the gentle heart, love is always sheltered”).

The genius of Dante and Cavalcanti brought the movement to its full power. Dante pointed out in *Il convivio* (“The Banquet”) that he deliberately chose sweet and musical language for his love poetry, and the lyrics to Beatrice that interlace *La vita nuova* (“The New Life”) amply prove his success. His notion of love is a very exalted one: even while she was alive, Beatrice was pictured as an angelic presence, and after her death, Dante gave her the role of his divine guide in *La divina commedia*.

The beatific quality suffusing Dante’s love for Beatrice is somewhat different from that which Cavalcanti expresses in his emotionally complex, often anguished love lyrics. But Cavalcanti, the poet of the complexities of love, contributed some of the finest examples of the *dolce stil nuovo*, for example, the sonnet that begins “Who is she coming, whom all gaze upon.” Cavalcanti was also the author of a famous and difficult canzone analyzing the nature of love, called “Donna me prega” (“A lady entreats me”), which suggests the notion that love exists when a man encounters a woman who corresponds to an ideal image in his mind and ceases to exist when this correspondence of images ceases.

The influence of the *stilnovisti* extended far beyond their own period, affecting the poetry of Petrarch, Lorenzo de’ Medici (who consciously imitated them), Michelangelo, Pietro Bembo, Torquato Tasso, Dante Gabriel Rossetti, and Ezra Pound.

Dolci, Carlo, byname CARLINO (b. May 25, 1616, Florence [Italy]—d. Jan. 17, 1686, Florence), Italian painter, one of the last representatives of the Florentine school of Baroque painting, whose mainly devotional works are characterized by their oversweet and languid piety.

Dolci studied with a minor local painter and at an extremely early age showed a talent for portrait painting. Failing to develop significantly in this direction, however, he vowed, inspired by Counter-Reformation teachings, to devote his career to painting religious subjects. At a time when other Florentine artists migrated to Rome, the centre of monumental Baroque painting, Dolci remained in Tuscany and developed his manner out of the more sober, static native traditions of Florence.

Although he possessed little genius or in-

Dolci, self-portrait, oil painting, in the Uffizi Gallery, Florence

© SCALA/Art Resource, New York City

ventiveness, Dolci painted pictures that were highly popular in his day. The figures in his dramatically concentrated compositions are typically half-length and treated with refinement of detail, soft colour, and strong contrasts of light and dark.

doldrums, equatorial regions of light ocean currents and winds within the intertropical convergence zone, a belt of converging winds and rising air encircling the Earth near the Equator. The northeast and southeast trade winds meet there; this meeting causes slow air uplift and produces the doldrums. They occur along the Equator in the Indian and western Pacific oceans and slightly north of the Equator off the African and Central American west coasts. The crews of sailing ships dreaded the doldrums because their ships were often becalmed there; the designation for the resultant state of depression was apparently thus extended to these geographic regions themselves.

Dole, also spelled DÔLE, town, Jura *département*, Franche-Comté region, eastern France. The town lies along the Doubs River and the Rhine-Rhône Canal, southeast of Dijon. It was called Dolla under the Romans. It was the seat of the dukes of Burgundy in medieval times and was the capital (1332–1674) of Franche-Comté. It belonged to the house of Habsburg from 1493 until the Peace of Nijmegen made it French in 1678, when its *parlement* and university (founded 1423) were transferred to Besançon. The birthplace of Louis Pasteur in

The Church of Notre-Dame, Dole, Fr., on the Rhine-Rhône Canal

© A. Parnet/Explorer

Dole is preserved as a monument, and the Hôpital Pasteur is housed in a 17th-century building. The Gothic-style Church of Notre-Dame dates from the 16th century. Dole has metal and sanitary porcelain manufacturing and trades in grain, wine, and cheese. Pop. (1990) 27,860.

Dole, Robert J., in full ROBERT JOSEPH DOLE, byname BOB DOLE (b. July 22, 1923, Russell, Kan., U.S.), U.S. senator and Republican congressional leader who was his party’s candidate for the presidency in 1996.

Dole was born into a working-class family and left the University of Kansas to serve in the army during World War II. He became a second lieutenant and was seriously wounded during fighting in Italy. His recuperation from almost total paralysis took nearly four years, and, despite three major operations, he was left without the use of his right arm and hand. He returned to school and graduated with a law degree from Washburn Municipal University, Topeka, Kan.

From 1951 to 1953 Dole was a Republican member of the Kansas state legislature, and he thereafter served four terms as the Russell county prosecuting attorney. From 1961 to 1969 he was a Republican member of the U.S. House of Representatives. He was first elected to the U.S. Senate in 1968 and was reelected repeatedly thereafter. He also served (1971–73) as chairman of the Republican National Committee under President Richard M. Nixon.

In 1984 Dole became leader of his party in the Senate, and he twice served as majority leader (1984–86; 1994–96). He was selected by President Gerald R. Ford as the vice-presidential candidate in the 1976 election, and after their defeat he unsuccessfully sought the Republican presidential nomination in 1980 and 1988. After finally clinching his party’s nomination for president in March 1996, he retired from the Senate in June to wholly devote himself to the campaign, naming former congressman Jack Kemp as his running mate. Dole was defeated in November when President Bill Clinton won election to a second term.

Dole’s political career was characterized by pragmatic conservatism. His second wife, Elizabeth Hanford Dole, whom he married in 1975, also held a number of influential U.S. governmental posts.

Dole, Sanford Ballard (b. April 23, 1844, Honolulu, Hawaiian Islands [U.S.]—d. June 9, 1926, Honolulu), first president of the Republic of Hawaii (1894–1900), and first governor of the Territory of Hawaii (1900–03) after it was annexed by the United States.

The son of American Protestant missionaries, Dole spent two years in the United States (1866–68) studying at Williams College in Williamstown, Mass. He then returned to Hawaii, practiced law in Honolulu (1869–87), and was twice elected to the Hawaiian legislature (1884, 1886). An opponent of the policies of King Kalakaua, Dole was a leader of the reform movement that brought about the adoption of a constitution in 1887. Also in 1887, he was appointed a justice of the Supreme Court of Hawaii.

In January 1893 Dole agreed to serve as the leader of the committee, acting for Hawaiian sugar interests and their American allies, that was formed to overthrow Queen Liliuokalani (who had succeeded her brother, Kalakaua, in 1891) and to seek annexation of Hawaii by the United States. The committee deposed the queen and installed a provisional government with Dole as president (Jan. 17, 1893), but annexation was blocked when President Grover Cleveland withdrew an annexation treaty from the Senate and demanded the restoration of Liliuokalani to the throne. Refusing to recognize Cleveland’s authority in the matter, Dole and his colleagues established the Republic of

Hawaii (1894), with Dole as president, and continued to seek annexation. When, finally, in 1900 Congress created the Territory of Hawaii, Dole was appointed the first territorial governor by President William McKinley. In 1903 he resigned to become judge of the U.S. district court of Hawaii, a post he held until his retirement in 1915.

dolerite (petrology): see diabase.

Dolet, Étienne (b. Aug. 3, 1509, Orléans, France—d. Aug. 3, 1546, Paris), French Humanist, scholar, and printer whose *Commentarii linguae Latinae* contributed notably to Latin scholarship. He is often described as “the first martyr of the Renaissance.”

After studying at Paris and the universities of Padua and Venice, Dolet settled in Toulouse, France. His quarrelsome temperament, unrestrained enthusiasm for Renaissance learning, and anticlericalism involved him in personal and public controversies. He was banished

Dolet, engraving, c. 1546

J. E. Bulloz

from the University of Toulouse and moved to Lyon, where for a time he was imprisoned for the justifiable homicide of a painter; he was released by royal pardon.

An ardent Ciceronian, he answered Erasmus' attack on slavish imitations of Cicero's style with *Dialogus de imitatione ciceroniana* (1535) and in 1536 published the first volume of his *Commentarii*; the second followed in 1538. This work was dedicated to Francis I, who gave him permission to set himself up as a printer. His first publication, *Cato Christianus* (“The Christian Cato”), was a profession of his creed as a Christian moralist. *Cato* was followed by Dolet's translations and editions of classical authors, Erasmus, the New Testament and Psalms, and Rabelais.

He was thrice accused of atheism and imprisoned (1542 and 1544) on the double charge of having published Calvinistic works and a dialogue by Plato denying the immortality of the soul; his third imprisonment was in 1546. He was finally condemned by the theological faculty of the Sorbonne and, having first been tortured, was burned at the stake.

Whether Dolet was a Protestant or an anti-Christian rationalist and freethinker is debatable. He was condemned by both Calvin and the Roman Catholic church, but he published many religious books and repeatedly advocated the reading of the Scriptures in the vernacular. It seems likely that his fate was the result of his capacity to make enemies rather than the result of his opinions.

Dolgan, Turkic-speaking people constituting the basic population of the Taymyr autonomous okrug, far above the Arctic Circle in north-central Russia. They numbered about 6,000 in the late 20th century. The Dolgan migrated to the area from the southwest presumably in the 18th century. The nucleus of the Dolgan people was formed from a few

Evenk clans that subsequently adopted a dialect of the Turkic-speaking Yakuts.

In the 1970s the Dolgan were principally reindeer herders, collectivized under the Soviets, though their way of life was only gradually becoming less nomadic. Vegetable gardening had become important, along with traditional game hunting. Before the Russian Revolution of 1917 they were organized into clans, headed by clan elders.

Dolgo-Nenets (Russia): see Taymyr.

Dolgoprudny, also spelled DOLGOPRUNDNYJ, city, Moscow oblast (province), western Russia. It is situated north of Moscow, where the Savyolovo railway crosses the Moscow Canal, linking the capital with the Volga River. Dolgoprudny appeared in the first Soviet five-year plans as a centre for airship construction. It now has machine-building and engineering industries. It is the site of the Moscow Institute of Physics and Technology, the Central Aerological Observatory, and the Pryanishnikov All-Russia Research Institute of Fertilizers and Agropedology. Pop. (1995 est.) 68,500.

Dolgoruky FAMILY, Dolgoruky also spelled DOLGORUKOV, a Russian princely family whose origins are believed by some to go back to Yury Dolgoruky (1090–1157), a son of Vladimir II Monomakh of Kiev. The Dolgorukys produced well-known statesmen, military leaders, and men of letters.

Yury Alekseyevich Dolgoruky (d. 1682) was a high-ranking nobleman and military commander who achieved a number of victories in the Russo-Polish War of 1654–57. In 1676 he was appointed guardian of the child tsar Fyodor Alekseyevich; he was killed during the Moscow Uprising of 1682. Yakov Fyodorovich Dolgoruky (1639–1720), a close associate of Peter I the Great, served in the military and was held prisoner in Sweden for 10 years. After returning to Russia (1711), he became a senator and was appointed president of the Auditing Collegium. Grigory Fyodorovich Dolgoruky (1656–1723) was ambassador to Poland (1701–21) and helped conclude a treaty of alliance with Poland (1701) and the Narva Alliance (1704).

Vasily Vladimirovich Dolgoruky (q.v.) became a high-ranking military officer and served on the Supreme Privy Council. His distant cousin, the diplomat Vasily Lukich Dolgoruky (q.v.), also served on the Supreme Privy Council.

Yury Vladimirovich Dolgoruky (1740–1830), a memoirist, served in the armies of the field in the Seven Years' War (1756–63) and in two of the Russo-Turkish Wars (1768–74 and 1787–91). Ivan Mikhaylovich Dolgoruky (1764–1823), vice-governor of Penza (1791–97) and governor of Vladimir (1802–12), wrote lyric poetry, comedies, and reminiscences that characterized the culture, the upbringing, and the education of children of the nobility.

Dolgoruky, Vasily Lukich, Knyaz (Prince) (b. c. 1670—d. Nov. 8 [Nov. 19, New Style], 1739, Novgorod, Russia), Russian diplomat and statesman who acquired political power for himself and his family during the reign of Tsar Peter II (reigned 1727–30).

Dolgoruky began his diplomatic career as an aide to his uncle Yakov Fyodorovich in Paris (1687). In 1700 he accompanied another uncle, Grigory Fyodorovich, to Poland and in 1706 replaced him as Russian ambassador there. He subsequently served as Russia's ambassador to Denmark (1707–20), France (1721–22), and Sweden (1725–27).

He shortly secured a position on the powerful Supreme Privy Council and arranged the betrothal of the young tsar to his niece, Yekaterina Alekseyevna. Peter II died suddenly (1730) before the marriage could take place, and Dolgoruky's involvement in intrigues concerning the succession—including the manu-

facture of a letter purporting to be the tsar's last will in which he appointed Yekaterina his successor—resulted in his banishment (1730), first to Siberia and then to the Solovetsky monastery. In 1739 he and two other Dolgorukys were found guilty of the forgery and beheaded.

Dolgoruky, Vasily Vladimirovich, Knyaz (Prince) (b. January 1667, Russia—d. Feb. 11 [Feb. 22, New Style], 1746, St. Petersburg), military officer who played a prominent role in political intrigues against Peter I the Great (ruled 1682–1725) and Empress Anna (ruled 1730–40) of Russia.

A member of the influential Dolgoruky family, Vasily Vladimirovich participated in the Great Northern War (1700–21). In 1707–08 he suppressed a Cossack rebellion led by Ataman Bulavin, and thereby won the confidence of Tsar Peter I.

Nevertheless, Dolgoruky apparently opposed Peter's innovations and reforms. Accused of conspiring with a group of boyars (i.e., high-ranking noblemen) to replace Peter on the throne with Peter's more traditionally minded son Alexis, he was deprived of his rank and title and sent into exile (1718).

Pardoned in 1724, Dolgoruky was restored to favour by Peter's successors. In 1728 he became field marshal and was appointed to the Supreme Privy Council (the governmental body that determined policy), on which he served with his distant cousin Vasily Lukich Dolgoruky.

In 1730, when Peter II died, Dolgoruky supported the accession of Anna Ivanovna (a niece of Peter I) to the throne. He also helped compose the set of “conditions,” which were intended to transfer real authority to the Supreme Privy Council. Anna was compelled to accept them before becoming empress, but she repudiated them shortly after arriving in Moscow and then abolished the Supreme Privy Council. Dolgoruky was again deprived of his rank and title and banished, first to Ivangorod in northwestern Russia, and then (1739) to Solovetsky Monastery on Solovetsky Island in the White Sea.

In 1741, when Empress Elizabeth attained the throne, Dolgoruky's rank and title were restored to him and he was named president of the War College.

Dolin, Sir Anton, original name SYDNEY FRANCIS PATRICK CHIPPENDALL HEALEY-KAY (b. July 27, 1904, Slinfold, Sussex, Eng.—d. Nov. 25, 1983, Paris, France), British ballet dancer, choreographer, and director who, with

Dolin in *Bluebeard*, 1942
Fred Fehl

his frequent partner Alicia Markova, founded the Markova-Dolin companies and London's Festival Ballet.

Trained by the notable Russian teachers Serafima Astafieva and Bronislava Nijinska, Dolin began his ballet career in 1921 in the corps de ballet of Sergey Diaghilev's Ballets Russes. As a soloist with Diaghilev's company, he created the leading role in Nijinska's *Train Bleu* (1924) and an important role (one of two Servants) in George Balanchine's *Prodigal Son* (1929). Dolin was considered to be one of the finest partners of his time. He eventually danced leading roles in numerous classical ballets but was also noted for such creations as Satan in NINETTE DE VALOIS'S *Job* (1931) and the title role in Michel Fokine's *Bluebeard* (1941).

Active in the formation of many companies, Dolin helped establish the Camargo Society (1930-33), whose productions greatly influenced British ballet, and he danced leading roles in the first productions of the Vic-Wells Ballet (now Royal Ballet). He joined the Ballet Theatre, New York City (now American Ballet Theatre) at its inception in 1940, remaining until 1946 as a dancer and choreographer. He was also director and principal male dancer of the Markova-Dolin Ballet (1935-38; 1945-49). In 1949 he and Markova founded another company that in 1950 became London's Festival Ballet; Dolin was premier danseur and artistic director until 1961. He then organized and toured with the troupe Stars of the Ballet, worked as choreographer and director of the Rome Opera Ballet, and served as artistic adviser to Les Grands Ballets Canadiens. He was knighted in 1981.

As a choreographer Dolin restaged *Swan Lake*, *Giselle*, and the last act of *The Sleeping Beauty*, which he presented alone as *Princess Aurora* (1941). His original ballets include *Capriccioso* (1940), *The Romantic Age* (1942), and *Variations for Four* (1957), a popular all-male divertissement. Dolin is particularly noted for his reconstruction (1941) of Jules Perrot's classical divertissement, *Pas de Quatre*. His many books on the dance include *Ballet Go Round* (1938), *Pas de Deux*, *The Art of Partnering* (1949), *Alicia Markova* (1953), *Autobiography* (1960), and *The Sleeping Bal-lerina: The Story of Olga Spessivtzeva* (1966).

doline (landform): see sinkhole.

Dolittle, Doctor, hero of 10 children's books by the British-American author Hugh Lofting (q.v.).

Dolj, județ (county), southwestern Romania, bounded on the south by Bulgaria. The Jiu and Teslui rivers drain the county southward through lowlands and rolling hills to the Danube River, which marks the southern boundary. Craiova (q.v.), the county capital, has machinery, metallurgical, and chemical industries. Textiles, leather goods, wood products, and building materials are manufactured in Craiova and several smaller towns, including Târgu Jiu, Filiși, and Ișalnița. A coalfield is worked at Petroșani, and a hydroelectric plant operates on the Jiu River near Craiova. Calafat, Bechet, and Corabia are small ports, located on the Danube. There is a university in Craiova. Area 2,862 square miles (7,413 square km). Pop. (1992 prelim.) 761,100.

doll, a child's toy modeled in human or animal form. It is perhaps the oldest plaything.

No dolls have been found in prehistoric graves, probably because they were made of such perishable materials as wood and fur or cloth, but a fragment of a Babylonian alabaster doll with movable arms has been recovered. Dolls dating from 3000-2000 BC, carved of flat pieces of wood, geometrically painted, with long, flowing hair made of strings of

(Top left) Inca figurine made of spring oyster shells buried with child in the Peruvian Andes, c. 1500; (top right) doll with bisque head, human hair, and kid leather body, manufactured in the late 19th century, probably in Germany; (bottom) Billions of Dreams™ Barbie, designed to honour the production of the 1,000,000,000th Barbie doll

clay or wood beads, have been found in some Egyptian graves.

Some ancient dolls may have had religious meaning, and some authorities often argue that the religious doll preceded the toy. In ancient Greece and Rome, marriageable girls consecrated their discarded dolls to goddesses. Dolls were buried in children's graves in Egypt, Greece, and Rome and in early Christian catacombs. Ancient rag, or stuffed, dolls have been found, as well as dolls crocheted of bright wool and others with woolen heads, clothed in coloured wool frocks.

As early as 1413 there were *Dochenmacher*, or doll makers, in Nürnberg, Germany, which, from the 16th to the 18th century, was the leading manufacturer of dolls and toys. Paris was another early mass-producer of dolls, making chiefly fashion dolls. Doll's houses were also popular in Europe from the 16th century.

Doll heads were made of wood, terra-cotta, alabaster, and wax—the last a technique perfected in England by Augusta Montanari and her son Richard (c. 1850-87), who popularized infant dolls. About 1820, glazed porcelain (Dresden) doll heads and unglazed bisque (ceramic) heads became popular. A French bisque doll made by the Jumeau family in the 1860s had a swivel neck; the body was made of kid-covered wood or wire or of kid stuffed with sawdust, a type of manufacture that remained common until it was supplanted by molded plastics in the 20th century. Socket joints, movable eyes, dolls with voices, and walking dolls were introduced in the 19th century, as were paper-doll books and dolls of India rubber or gutta-percha. The period from 1860 to 1890 was the golden age of the elaborately dressed Parisian bisque fashion dolls and the smaller "milliner's models."

The oldest American dolls may be those found in Inca and Aztec graves, such as those near the pyramids of Teotihuacán. Colo-

nial dolls mostly followed European models. Among American Indian dolls, the kachina doll of the Pueblo Indians is noteworthy.

In Japan, dolls are more often festival figures than playthings. At the girls' festival held in March, dolls representing the emperor, empress, and their court are displayed; girls from 7 to 17 visit each other's collections, and refreshments are offered: first, to their majesties, then to the guests, in a ritual more than 900 years old. Japanese boys also have an annual doll festival, from the first May after they are born until they are about 15 years old. Warrior dolls, weapons, banners, and legendary-figure groups are displayed to encourage chivalrous virtues.

In India, elaborately dressed dolls were given to child brides by both Hindus and Muslims. In Syria, girls of marriageable age hang dolls in their windows. In South Africa, among the Mfengu people, every grown girl is given a doll to keep for her first child; on its birth, the mother receives a second doll to keep for the second child.

In the 20th century, notably popular dolls included the teddy bear (1903); the Kewpie Doll (1903); the Bye-lo Baby, who closed her eyes in sleep (1922); the Dyde and Wetsy Betsy dolls (1937); the Barbie doll (1959); Cabbage Patch Kids (1983); and the American Girls Collection (1986).

dollar, originally, a silver coin that circulated in many European countries; in modern times, the name of the standard monetary unit in the United States, Canada, Australia, New Zealand, and other countries. The Spanish peso, or piece of eight, which circulated in the Spanish and English colonies in America, was known as a dollar by the English-speaking peoples. Familiarity with this coin resulted in the official designation of the United States monetary unit as the dollar in 1792. Canada adopted the dollar and monetary decimal system in 1858; Australia in 1966; and New Zealand in 1967.

The word itself is a modified form of the Germanic word *thaler*, a shortened form of *Joachinst(h)aler*, the name of a silver coin first struck in 1519 under the direction of the count of Schlick, who had appropriated a rich silver mine discovered in St. Joachimsthal (Joachim's dale), Bohemia. These coins were current in Germany from the 16th century onward, with the various spelling modifications such as *daler*, *dalar*, *daalder*, and *tallero*. Only in 1873 was the *thaler* replaced by the mark as the German monetary unit.

In the United States, paper money has been issued in dollar amounts since 1861. Portraits of American political figures appear on the various denominations of U.S. banknotes:

denomination	portrait on bill
\$1	George Washington
\$2	Thomas Jefferson
\$5	Abraham Lincoln
\$10	Alexander Hamilton
\$20	Andrew Jackson
\$50	Ulysses S. Grant
\$100	Benjamin Franklin
\$500	William McKinley
\$1,000	Grover Cleveland
\$5,000	James Madison
\$10,000	Salmon P. Chase

Dollar, William, in full WILLIAM HENRY DOLLAR (b. April 20, 1907, St. Louis, Mo., U.S.—d. Feb. 28, 1986, Flourtown, Pa.), American ballet dancer, choreographer, and ballet master associated with numerous American companies for more than 30 years.

Trained almost entirely in the United States, Dollar studied with the choreographers George Balanchine and Michel Fokine and with Mikhail Mordkin and Pierre Vladimirov, both formerly premiers danseurs in Russia. Dollar was a leading dancer with the American Ballet (1936-37), Ballet Caravan (1936-38), and the American Ballet Caravan (1941)—predecess-

Dollar and Melissa Hayden in *The Duel*

sors of the New York City Ballet (established 1948). His creations with those companies included roles in Balanchine's versions of *Le Baiser de la fée* ("The Fairy's Kiss"; 1937), *The Card Party* (1937; later known as *Card Game*), and *Transcendence* (1935), which Balanchine choreographed especially for him.

His first ballet, *Classic Ballet* (1936), was choreographed with Balanchine; Dollar restaged this work in 1944 as *Constantia* for Ballet International. He choreographed many other ballets, of which his best known is *The Duel* (1950) he originally staged in 1949 as *Le Combat* for Roland Petit's Ballets de Paris. His later works included *The Leaf and the Wind* (1954) and *Mendelssohn Concerto* (1958). He worked with ballet companies in Brazil, Japan, and Monte Carlo.

Dollar Diplomacy, foreign policy created by U.S. president William Howard Taft (served 1909-13) and his secretary of state, Philander C. Knox, to ensure the financial stability of a region while protecting and extending American commercial and financial interests there. It grew out of President Theodore Roosevelt's peaceful intervention in the Dominican Republic, where U.S. loans had been exchanged for the right to choose the Dominican head of customs (the country's major revenue source).

Under the name of Dollar Diplomacy the Taft administration engineered such a policy in Nicaragua. It supported the overthrow of José Santos Zelaya and set up Adolfo Díaz in his place, it established a collector of customs, and it guaranteed loans to the Nicaraguan government. The resentment of the Nicaraguan people, however, eventually resulted in U.S. military intervention as well.

Taft and Knox also attempted to promulgate Dollar Diplomacy in China, where it was even less successful, both in terms of U.S. ability to supply loans and in terms of world reaction. The dismal failure of Dollar Diplomacy—from its simplistic assessment of social unrest to its formulaic application—caused the Taft administration to finally abandon the policy in 1912.

Dollar diplomacy has come to refer in a disparaging way to the heedless manipulation of foreign affairs for strictly monetary ends.

Dollfus, Audouin, in full AUDOUIN-CHARLES DOLLFUS (b. Nov. 12, 1924, Paris, France), French astronomer, successor to Bernard Lyot as the principal French authority on the solar system.

Dollfus made several balloon flights for high-altitude observations, including the first stratospheric ascension in France. On the basis of comparative light-polarizing qualities, he concluded that the surface material of Mars consists of pulverized limonite (an iron oxide, Fe₂O₃) and prepared a map of Venus showing what he believed to be permanent features. On Dec. 15, 1966, he discovered Saturn's 10th known satellite, Janus.

Dollfuss, Engelbert (b. Oct. 4, 1892, Texing, Austro-Hungarian Empire—d. July 25, 1934, Vienna, Austria), Austrian statesman and, from 1932 to 1934, chancellor of Austria, who destroyed the Austrian Republic and established an authoritarian regime based on conservative Roman Catholic and Italian Fascist principles.

After studying law and economics in Vienna and Berlin, Dollfuss became secretary to the Lower Austrian Peasant Federation and, in 1927, director of the Lower Austrian chamber of agriculture. He was a member of the conservative and clerically oriented Christian Social Party, the core of whose constituency came from Austria's conservative peasantry. Dollfuss rose rapidly in Austrian politics, serving as president of the federal railways in 1930 and as minister of agriculture from 1931. In May 1932 he became chancellor, heading a conservative coalition led by the Christian Social Party.

Faced with a severe economic crisis caused by the Great Depression, Dollfuss decided against joining Germany in a customs union, a course advocated by many Austrians. He was in part dissuaded by a League of Nations loan of \$9,000,000 and by the fear of Allied

Dollfuss, 1934
UPI

countermeasures. Severely criticized by both Social Democrats and nationalists, he countered by drifting toward an increasingly authoritarian regime. The Italian leader Benito Mussolini became his principal foreign ally. Italy guaranteed Austrian independence at Riccione (August 1933), but in return Austria had to abolish all political parties and reform its constitution on the Fascist model. Dollfuss' attacks on Parliament, begun in March 1933, culminated that September in the permanent abolition of the legislature and the formation of a corporate state based on his Vaterländische Front ("Fatherland Front"), with which he expected to replace Austria's political parties. In foreign affairs he steered a course that converted Austria virtually into an Italian satellite state. Hoping therewith to prevent Austria's incorporation into Nazi Germany, he fought his domestic political opponents along fascist-authoritarian lines.

In February 1934 paramilitary formations loyal to the chancellor crushed Austria's Social Democrats in bloody encounters. With a new constitution of May 1934, his regime became completely dictatorial. In June, however, Germany incited the Austrian Nazis to civil war. Dollfuss was assassinated by the Nazis in a raid on the chancellery.

Döllinger, Johann Joseph Ignaz von (b. Feb. 28, 1799, Bamberg [now in Germany]—

d. Jan. 10, 1890, Munich, Ger.), German historical scholar, prominent Roman Catholic theologian who refused to accept the doctrine of papal infallibility decreed by the first Vatican Council (1869-70). He joined the Old Catholics (Altkatholiken), those who separated from the Vatican after the council but believed they maintained Catholic doctrine and traditions.

Ordained in 1822, he became professor of canon law and church history at Munich in 1826. From 1835 he was a member of the Bavarian Royal Academy of Sciences and served as its president from 1873. Though he lost his professorship in 1847 for protesting the dismissal of four colleagues by King Ludwig I of Bavaria, he was given posts that made him second to the archbishop of Munich and was reappointed professor of church history in 1849. Döllinger was a brilliant scholar whose embrace of modern historical criticism and whose belief in religious freedom brought him into conflict with papal policy. His opposition to the Ultramontanists, those who supported papal infallibility, led to his designation as the leader of the antipapal party in Germany.

In 1869 Döllinger wrote a series of articles, later enlarged and published as *Der Papst und das Konzil* (1869; *The Pope and the Council*), under the pen name Janus. This book, which criticized the Vatican Council and the doctrine of infallibility, immediately was placed on the Vatican's *Index of Forbidden Books*.

After his refusal to accept the doctrine of papal infallibility, Döllinger was excommunicated (1871) but was elected rector of Munich University in the same year. Döllinger and his colleagues, all excommunicated, held a congress to oppose the council's dogmas at Munich on Sept. 22, 1871; it was attended by 300 Old Catholics and Eastern Orthodox, Anglican, and Lutheran sympathizers. A committee, of which Döllinger was a member, drew up a doctrinal basis and a program for separate organization. According to Döllinger, it was the vocation of the Old Catholic communion to protest the Vatican dogmas, to support a Catholic church free from error, and to reunite Christendom.

Dollmann, Georg von, in full GEORG CARL HEINRICH VON DOLLMANN (b. Oct. 21, 1830, Ansbach, Bavaria [now in Germany]—d. March 31, 1895, Munich, Ger.), German architect, builder of three grandiose curiosities sponsored by the mentally ill king Louis (Ludwig) II of Bavaria: Linderhof (1869-78), Neuschwanstein (1869-86), and Herrenchiemsee (1878-85; incomplete). The neo-Baroque or neo-Rococo Linderhof is especially incongruous in its mountainous setting. For Neuschwanstein, which was intended to suggest the medieval Teutonicism of Richard Wagner's opera *Tannhäuser* (1845), Dollmann utilized Christoph Jank's design for an inflated Wartburg (castle near Eisenach, Thuringia). Herrenchiemsee was planned as a replica of the French royal residence at Versailles.

Dollond, George (b. Jan. 25, 1774, London, Eng.—d. May 13, 1852, London), British optician who invented a number of precision instruments used in astronomy, geodesy, and navigation.

Throughout most of his life, he worked for the family firm of mathematical instrument makers, assuming full control after the retirement in 1819 of his uncle Peter Dollond. His micrometer made of rock crystal, announced in 1821, was used by the English astronomer William Rutter Dawes in measuring close double stars. Other inventions followed, including improvements to astronomical and navigation devices. Dollond received the council medal of the Great Exhibition of 1851 for his atmospheric recorder that simultaneously measured

and recorded on paper tape temperature, atmospheric pressure, wind speed and direction, evaporation, and electrical phenomena.

Dollond, John (b. June 10, 1706, London, Eng.—d. Nov. 30, 1761, London), British maker of optical and astronomical instruments who developed an achromatic (non-colour-distorting) refracting telescope and a practical heliometer, a telescope used to measure the Sun's diameter and the angles between celestial bodies. Dollond became proficient in optics and astronomy and, in 1752, joined his eldest son, Peter, in an optical business. Two years later he introduced his heliometer.

Though Dollond was feted late in life for inventing the achromatic lens, the originator was actually Chester Moor Hall, who had combined flint and crown glass for the same purpose a generation earlier. In 1765 Dollond's son Peter invented the triple achromatic lens still in wide use.

Dollo's law, biological principle, formulated about 1890 by Louis Dollo, a French-born Belgian paleontologist, that evolution is not reversible; *i.e.*, structures or functions discarded during the course of evolution do not reappear in a given line of organisms. The hypothesis was first advanced by a historian, Edgar Quinet.

Dolly Varden trout, also called **MALMA**, or **BULL TROUT** (species *Salvelinus malma*), char, of the family Salmonidae, found in northwestern North America and northeastern Asia. It has yellow spots on the back, reddish spots on the sides, and a white edge on the lower fins. Because it eats the eggs and young of salmon,

Dolly Varden trout (*Salvelinus malma*)

it is destroyed as a pest in Alaska. It often migrates to sea, grows large and silvery, and returns to spawn. A good food and game fish, it has an average size of about 0.5 to 1.8 kg (1 to 4 pounds) but may be larger.

dolma, in Middle Eastern and Greek cuisine, any of various stuffed vegetable dishes, notably, the young leaves of the grapevine stuffed with a lemon-flavoured mixture of rice, onion, and frequently ground lamb. Although dolmas are usually eaten cold as an appetizer, Greek *dolmades* with lamb are served hot as a main course with an *avgolemono* sauce of egg yolks and lemon juice. Other vegetables such as zucchini, green peppers, cabbage, and onions are similarly prepared.

dolmen, prehistoric monument usually consisting of several great stone slabs set edgewise

Dolmen at Pentre Evan, Dyfed, Wales

in the earth to support a flat stone, which served as a roof. Designed as a burial chamber, the structure is typical of the Neolithic Period in Europe. The word is Celtic in origin but probably is not Breton. Dolmens, although found in covered form as far east as Japan, are mainly confined to Europe, the British Isles, and northern Africa.

Dolmetsch, (Eugène) Arnold (b. Feb. 24, 1858, Le Mans, France—d. Feb. 28, 1940, Haslemere, Surrey, Eng.), French-born British musician whose lifework, pursued in the face of prolonged indifference and misunderstanding, established the modern search for authen-

Dolmetsch, pen-and-ink drawing by Edmond X. Kapp, 1920; in a private collection

Edmond X. Kapp

ticity in the performance and instrumentation of early music. His craftsmanship in restoring and reproducing early musical instruments, his insistence on consultation of source material, coupled with his intuitive understanding, gave him remarkable insight into the problems of presenting music of J.S. Bach's generation and earlier.

Dolmetsch learned piano and organ building from his father and grandfather, and, after study at the Brussels Conservatory and the Royal College of Music in London, he taught violin. He discovered British Museum manuscripts of viol music by early English composers, began investigating how to perform their music in authentic style, and in 1890 gave his first viol concert.

With his wife and Kathleen Salmon he formed a trio for the performance of early music on authentic instruments. His 1902 concert tour of the U.S. prompted the Chickering factory in Boston to extend its facilities to him. There he supervised the building of harpsichords, lutes, and viols (1905–09). From 1911 to 1914 he was at the Gaveau factory in Paris. After World War I he built the first successful modern recorders.

Like George Bernard Shaw, who reviewed his concerts with enthusiasm, Dolmetsch was a rebel whose reforms aroused alarm and fascination. His work slowly gained acceptance after 1914. He published several editions of early music, and his book, *The Interpretation of the Music of the XVII and XVIII Centuries* (1915; 1944), became a basic work in its field. Dolmetsch settled in England in 1914 and in 1916 established a centre for the study of early music in Haslemere. In 1928 the Dolmetsch Foundation was organized to support him and to spread his ideas.

Dolnośląkie, województwo (province), southwestern Poland. Lowlands in the north rise to mountains in the south. The provincial capital, Wrocław, is also the province's educational, cultural, and recreational centre. Densely populated, Dolnośląkie has one of Poland's most industrialized provincial economies, with mining, metallurgy, and the manufacture of textiles, machines, and vehicles. Good soils are the basis for extensive agriculture (wheat, rape, sugar beets, potatoes, vegetables). With

one-fourth of the land forested, the timber and papermaking industries thrive. There is a port on the Oder River at Wrocław, as well as an international airport at Wrocław-Strachowice. Area 7,702 square miles (19,948 square km). Pop. (2003 est.) 2,902,400.

Dolomieu, Dieudonné, also called **DÉODAT DE GRATET DE DOLOMIEU** (b. June 23, 1750, Dolomieu, near Tour-du-Pin, France—d. Nov. 26, 1801, Château-Neuf, Saône-et-Loire), French geologist and mineralogist after whom the mineral dolomite was named.

A member of the order of Malta since infancy, he was sentenced to death in his 19th year for killing a brother knight in a duel but was pardoned. He continued to study natural sciences, which he had begun earlier, and after giving up his commission as a carabineer, visited Spain, Sicily, the Pyrenees, and the Calabria region of southern Italy. Following a study of the Alps (1789–90), he described dolomite (1791). A member of Napoleon's expedition to Egypt (1798), he was captured on the way home and imprisoned at Messina. During his imprisonment he wrote his main treatise, *Sur la philosophie minéralogique et sur l'espèce minérale* (1801; "On Mineralogical Philosophy and on the Mineral Class"), on the margins of a Bible.

Consult the INDEX first

dolomite, type of limestone the carbonate fraction of which is dominated by the mineral dolomite, calcium magnesium carbonate [$\text{CaMg}(\text{CO}_3)_2$]. For detailed physical properties of the minerals, *see* carbonate mineral (table).

A brief treatment of dolomites follows. For full treatment, *see* MACROPAEDIA: Minerals and Rocks.

Dolomite is generally formed from limestone when the calcite (calcium carbonate, CaCO_3) in the limestone is replaced by calcium magnesium carbonate volume for volume. This process, known as dolomitization, may occur either soon after limestone deposition by exchange with sea water or after lithification by

Dolomite from Corydon, Ind.

By courtesy of the MacFall collection; photograph, Mary A. Root—EB Inc.

exchange with magnesium-bearing solutions. In most cases, textures coarsen during dolomitization and original structures (and textures) are eradicated. In a few instances, however, the structural and textural features of the parent limestone are preserved, resulting in a finely crystalline dolomite. Such rocks are considered primary dolomites and are typically associated with evaporites.

The mineral dolomite occurs in marbles, talc schists, and other magnesium-rich metamorphic rocks; textural studies have shown that at least some of this dolomite has formed on cooling from highly magnesian calcite, stable at higher temperatures. It occurs in hydrothermal veins, in cavities in carbonate rocks, and less commonly in various sedimentary rocks as a cement. It is most common as a rock-forming mineral in carbonate rocks. In dolomitized limestones it is a secondary replacement, and individual dolomite crystals cut across preexisting fossil outlines and other

textural features; fossil coral reefs are often replaced in this fashion.

Dolomitization is very selective, giving rise to interbedded limestone and dolomite. Modern dolomite forms in supratidal flats such as the Bahamas or in hypersaline lagoons associated with the precipitates of calcite, aragonite, magnesium calcite, gypsum, and anhydrite. Hydrothermal dolomite occurs in veins associated with lead, zinc, or copper ores, as well as with fluorite and barite.

Dolomites, Italian ALPI DOLOMITICHE, mountain group lying in the eastern section

Cima Pordoi seen from Sella Pass in the Dolomites, Italy

J. Allan Cash—Rapho/Photo Researchers

of the northern Italian Alps, bounded by the valleys of the Isarco (northwest), the Pusteria (north), the Piave (east and southeast), the Brenta (southwest), and the Adige (west). The range comprises a number of impressive peaks, 18 of which rise to more than 10,000 ft (3,050 m). The highest point is the Marmolada (10,964 ft), the southern face of which consists of a precipice 2,000 ft high. The range and its characteristic rock take their name from the 18th-century French geologist Dieudonné Dolomieu, who made the first scientific study of the region and its geology. Geologically, the mountains are formed of light-coloured dolomitic limestone, which erosion has carved into grotesque shapes. The resulting landforms include jagged, saw-edged ridges, rocky pinnacles, screes (pebble deposits) of limestone debris, deep gorges, and numerous steep rock faces at relatively low levels. Glaciated features occur at higher levels; 41 glaciers lie in the region. Many of the lower and more gentle scree slopes were once forested; only patches of woodland remain, however, interspersed with grassy meadows.

The main valleys provide relatively easy access to most parts of the Dolomites. The main north-south road uses the Campolongo Pass (6,152 ft). The east-west roads cross the well-known passes of Pordoi (7,346 ft), Falzarego (6,906 ft), Tre Croci (5,935 ft), Sella (7,404 ft), and Gardena (6,959 ft). The main centre of this tourist and mountain-climbing region is Cortina d'Ampezzo. Other resorts are Auronzo, San Martino di Castrozza, and Ortisei, with its narrow-gauge railway. On the western and southeastern margins, respectively, are located the larger towns of Bolzano and Belluno.

Most of the main peaks were first climbed in the 1860s and '70s by English mountaineers. Landslides after heavy rainstorms in the southern Dolomites twice caused the Vaiont Dam (on a tributary of the Piave River) to overspill and drown the village of Longarone, causing the loss of 2,000 lives in 1963 and the destruction of houses and communications in 1966.

Dolon Nor, also spelled DOLOON NUUR (China); see To-lun.

Dolores, Grito de, English CRY OF DOLORES (Mexican battle cry); see Grito de Dolores.

Dolores River, river in southwest Colorado, U.S., rising in La Plata Mountains and flowing southwest through deep canyons, past Do-

lores, then northwest through Paradox Valley, at the north end of which it is met by its chief tributary, the San Miguel River. It continues on past Gateway and across the Utah border to join the Colorado River near Moab after a course of about 250 mi (400 km). Melting snow produces high water in spring and early summer, but in midsummer the flow is a trickle. The Dolores and its tributaries are used for irrigation. The river probably was named Río de Nuestra Señora de los Dolores (River of Our Lady of Sorrows) by the Spanish trader Juan Maria Rivera c. 1765.

dolphin, either of two distinct types of animals: aquatic mammals of the whale families Delphinidae, Platanistidae, and Stenidae; or oceanic fishes of the family Coryphaenidae.

The mammalian dolphins are small, streamlined whales, usually with a well-defined, beaklike snout. They are often called porpoises, but that name is usually reserved for similar, but beakless, whales of the family Phocoenidae (see porpoise). Dolphins are

Bottle-nosed dolphins (*Tursiops truncatus*)

By courtesy of the Miami Seaquarium

popularly noted for grace, intelligence, playfulness, and friendliness to man. The most widely recognized species are the common and bottle-nosed dolphins (*Delphinus delphis* and *Tursiops truncatus*); both are of the family Delphinidae and are widely distributed in warm and temperate seas. These are probably the species of dolphins mentioned in the works of Aristotle, Aesop, Herodotus, the Plinys, and other early writers, often as a child's moust or the rescuer of someone lost in the sea.

The family Delphinidae contains 14 genera and about 32 species of dolphins distributed throughout the world oceans. Most are gray, blackish, or brown above and paler below, and most are about 1 to 4 metres (3 to 13 feet) long. Risso's dolphin (*Grampus griseus*), found in tropical and temperate seas throughout the world, is grayish in colour and lacks a beak. Teeth are usually lacking in the upper jaw. The pilot and killer whales, also members of this family, are much larger and, because of their size, are not usually thought of as dolphins.

The majority of the delphinids feed primarily on fish, and most of them are gregarious, appearing in groups of a few to several hundred. A number of species are attracted by moving ships, often accompanying them or leaping alongside and sometimes riding the wave created by the moving bow. The bottle-nosed dolphin, characterized by a "built-in smile" formed by the curvature of its mouth, has become a familiar performer in oceanaria. It has also become the subject of scientific studies because of its apparent intelligence and its ability to communicate with its kind through a range of sounds and ultrasonic pulses. It adapts to captivity better than the common dolphin, which is timid.

The Platanistidae, or river dolphins, comprise four genera and species of small, mainly freshwater dolphins found in South America

and Asia. They have long, slender beaks, reduced eyes, and poor vision. The Stenidae, or long-snouted dolphins, comprise three genera and eight species of little-known dolphins, also with long, slender beaks. They are found in tropical rivers and oceans and are sometimes included in the family Delphinidae.

The fish commonly known as a dolphin (*Coryphaena hippurus*), also called mahimahi and dorado, is a popular food and sport fish. Famed for the rapid changes undergone by its bright blue and gold coloration as it dies, this dolphin inhabits tropical and temperate waters throughout the world. It has a large, blunt head, a tapered body, and a slender, forked tail. The male, considerably larger than the female, may attain a length and weight of about 1.5 m and 30 kilograms (70 pounds). A swift carnivorous fish, this dolphin lives alone or in schools and feeds on invertebrates and other fishes. It and the similar, though smaller, pompano dolphin (*C. equiselis*) are the only living members of the family Coryphaenidae.

Dom, also called DOMRA, or DOMB, widespread and versatile caste of scavengers, musicians, vagabonds, traders, and, sometimes, weavers in northern India and the Himalayas. Some scholars regard the Doms as originating from an aboriginal tribe. They list seven endogamous subcastes. The Doms are completely outside Brahminic control. They have their own deities and an elaborate demonology. Considerable interest is attached to the Doms because there is reason to believe that the Gypsies, who originally came from India, are an offshoot of that caste. This connection is indicated by their use of the name Rom for themselves, a variant pronunciation of Dom; Syrian Gypsies refer to themselves as Doum.

Domagk, Gerhard (b. Oct. 30, 1895, Lagow, Brandenburg, Ger.—d. April 24, 1964, Burgberg, near Königsfeld, W.Ger.), German bacteriologist and pathologist who was awarded the 1939 Nobel Prize for Physiology or Medicine for his discovery (announced in 1932) of the antibacterial effects of Prontosil, the first of the sulfonamide drugs.

After teaching at the universities of Greifswald (1924) and Munich (1925), Domagk became director of the I.G. Farbenindustrie (Bayer) Laboratory for Experimental Pathology and Bacteriology, Wuppertal-Elberfeld. There, in a systematic survey for new dyes

Domagk, c. 1960

Archiv für Kunst und Geschichte, West Berlin

and new drugs, he noticed the antibacterial action of one of the dyes against streptococcal infection in mice. The dye, Prontosil red, was then tried clinically.

Unable to accept the Nobel award at the time because of Nazi German policy, Domagk later (1947) received the gold medal and diploma.

He also was active in research on tuberculosis and cancer.

domain, in Anglo-American law, the absolute and complete ownership of land, or the land itself which is so owned. Domain is the fullest and most superior right of property in land. Domain as a legal concept is derived from the dominium of the Roman law, which included the right of property as well as the right of possession or use of the property. The English common-law adoption of dominium was not comprehensive, omitting some of the finer distinctions developed by the Roman law.

The concept has several specific applications. Land to which title is still retained by the United States, including agricultural and mineral land not yet granted to private owners, as well as land occupied by federal government buildings and facilities, is referred to as the public domain, which also describes the absolute ownership of such land by the United States. Eminent domain, in English common law, refers to the sovereign power of the king or state to appropriate private land for public use. *See also* eminent domain.

Dombes, historic region of east-southeastern France, once a sovereign municipality and now included in the *département* of Ain. From 1032, when the Kingdom of Arles, of which Dombes was part, passed to the Holy Roman

The *intendance* (administrative area) of Dombes in 1789

emperor Conrad II, effective authority in the region was exercised by local lords. After 1378 it was under the nominal authority of the kings of France but was actually ruled as an independent principality by the Bourbon family. Francis I of France seized it from the Bourbons in 1523, and, although Dombes was later restored to the House of Bourbon-Montpensier (1561), it ultimately returned to the French crown in 1762.

Dombrowski, Jan Henryk: *see* Dąbrowski, Jan Henryk.

dome, in architecture, hemispherical structure evolved from the arch, usually forming a ceiling or roof. Domes first appeared as solid mounds and in techniques adaptable only to the smallest buildings, such as round huts and tombs in the ancient Middle East, India, and the Mediterranean. The Romans introduced the large-scale masonry hemisphere. The dome exerts thrusts all around its perimeter, and the earliest monumental examples, such as the Roman Pantheon, required heavy supporting walls.

Byzantine architects invented a technique for raising domes on piers, permitting lighting and communication from four directions. The

Dome, showing pendentive construction; Hagia Sophia, Constantinople, 6th century

transition from a cubic base to the hemispherical dome was achieved by four pendentives, inverted triangular masses of masonry curved both horizontally and vertically, as shown in the figure. Their apexes rested on the four piers, to which they conducted the forces of the dome; their sides joined to form arches over openings in the four faces of the cube; and their bases met in a complete circle to form the dome foundation. The pendentive dome could rest directly on this circular foundation or upon a cylindrical wall, called a drum, inserted between the two.

Displaced architecturally by the light, vertical styles of Gothic architecture, the dome regained popularity during the European Renaissance and Baroque periods. Vaulting is simpler than doming, and so the effort and ingenuity devoted to doming rectangular structures must be explained principally by the symbolic character of the dome. The desire to observe tradition preserved the dome in the early era of iron and steel construction. The modern reinforced concrete slab used in vaulting can be curved in length as well as width to form a dome. Here the distinction between vaults and domes has lost its original significance, being based only on the type of curvature in the slab.

The geodesic dome (*q.v.*) is built up of triangular or polygonal facets that distribute stresses within the structure itself.

dome, in geology, any large or elliptical structure formed by the fractureless upwarping of rock strata. It is a type of anticline that lacks clear-cut elongation and that slopes outward in all directions from the highest point. Typical examples of such a dome can be found in the Black Hills of South Dakota in the western United States. Where strata plunge more or less uniformly toward surrounding lowlands, erosion may produce a series of concentric ridges with their steep slopes facing inward toward the centre. In some areas domes in which a layer of relatively impermeable shale overlies

Green Mountain, a nearly circular dome near Sundance, Wyoming

a layer of permeable sandstone are structural traps for oil and natural gas. The oil and gas migrate upward, becoming trapped against the shale at the uppermost part of such anticlinal formations.

dome, volcanic: *see* volcanic dome.

Dome of the Rock, Arabic QUBBAT AŞ-ŞAKHRAH, also called MOSQUE OF OMAR, shrine in Jerusalem that is the oldest extant Islamic monument. The rock over which the shrine was built is sacred to both Muslims and Jews. The Prophet Muḥammad, founder of Islām, is traditionally believed to have ascend-

Dome of the Rock in Jerusalem, built 685–691

D. Edwards / FPG/EB Inc

ed into heaven from the site. In Jewish tradition, it is here that Abraham, the progenitor and first patriarch of the Hebrew people, is said to have prepared to sacrifice his son Isaac. The Dome and Al-Aqsā Mosque are both located on the Temple Mount, the site of Solomon's Temple and its successors.

The Dome of the Rock was built between AD 685 and 691 by the caliph 'Abd al-Malik ibn Marwān, not as a mosque for public worship but rather as a *mashhad*, a shrine for pilgrims. It is virtually the first monumental building in Islamic history and is of considerable aesthetic and architectural importance; it is rich with mosaic, faience, and marble, much of which was added several centuries after its completion. Basically octagonal, the Dome of the Rock is more typically Roman or Byzantine than Islamic. A wooden dome—approximately 60 feet (18 m) in diameter and mounted on an elevated drum—rises above a circle of 16 piers and columns. Surrounding this circle is an octagonal arcade of 24 piers and columns. The outer walls repeat this octagon, each of the eight sides being approximately 60 feet (18 m) wide and 36 feet (11 m) high. Both the dome and the exterior walls contain many windows.

Christians and Muslims in the European Middle Ages believed the Dome itself to be the Temple of Solomon (Templum Domini). The Knights Templars were quartered there in the Crusades, and Templar churches in Europe imitated its plan.

Dōmei, abbreviation of ZEN NIHON RŌDŌ SŌDŌMEI, English JAPANESE CONFEDERATION OF LABOUR, Japan's second largest labour union federation until it disbanded in 1987. Dōmei was formed in 1964 by a merger of three politically moderate federations that opposed the leftist stance of the larger and more militant union Sōhyō. Unlike most Sōhyō members, who were public employees, most Dōmei members worked for private employers. Dōmei was a supporter of the Democratic Socialist Party and was affiliated with the International Confederation of Free Trade Unions. Dōmei disbanded in 1987 when many of its member unions joined with other private-sector unions to form a new confederation called Rengo.

Domenichino, original name DOMENICO ZAMPIERI (b. October 1581, Bologna, Papal States [Italy]—d. April 6, 1641, Naples), Italian painter who was a leading practitioner of Baroque classicism in Rome and Bologna.

He was trained in the academy of Lodovico Carracci and in 1602 was in Rome, where he joined the Bolognese artists at work under the direction of Annibale Carracci in the decoration of the Farnese Palace. He was employed by Cardinal Aldobrandini to decorate a room

"Last Communion of Saint Jerome," oil painting by Domenichino, 1614; in the Vatican Museum

SCALA—Art Resource

in the Villa Belvedere at Frascati with mythological frescoes and by Cardinal Farnese to paint a chapel in the Badia at Grottaferrata. Both fresco cycles reflect the spirit of Annibale Carracci, though their more rigidly classical schemes look forward to the "Scenes from the Life of St. Cecilia" that Domenichino painted between 1615 and 1617 for San Luigi dei Francesi and which are among his most successful works. His altarpiece of the "Last Communion of Saint Jerome" (1614; Vatican Museum) shows his concern for accurate facial expressions and tightly knit groupings of figures.

In 1617–18 Domenichino painted for Cardinal Borghese the celebrated canvas of "The Hunt of Diana" (Borghese Gallery, Rome). This work shows that he was a sensitive colourist, and its idyllic mood departs from the arid classicism of his frescoes. Between 1624 and 1628 he was occupied with the frescoed pendentives and apse of Sant'Andrea della Valle. Though Domenichino's work remained in great demand, there was a reaction against the rigid classicism of his style, and in the last works that he produced in Rome—four frescoed pendentives in San Carlo ai Catinari (1628–30) and the "Martyrdom of St. Sebastian" for St. Peter's, now in Santa Maria degli Angeli—he worked in a broader, less classical style. This closer approximation to the Baroque is also apparent in the frescoed "Scenes from the Life of St. Januarius" (1631–41, Cathedral of Naples). In Naples his style was less acceptable than it had proved in Rome, and he appears to have been the victim of systematic persecution by local artists, such as José de Ribera.

Throughout the 17th and 18th centuries Domenichino's paintings were regarded as second only to those of Raphael, but in the mid-19th century he fell from favour. His importance as a Baroque classicist was recognized again only in the 20th century. His work is marked by lucid and balanced compositions, even and serene lighting and subdued colours, and the sober expressions and restrained gestures of its figures. Domenichino also occupies an important place in the history of landscape

painting because his work had a profound influence on the classical landscapists Nicolas Poussin and Claude Lorrain.

Domenichino, II (composer): see Sarti, Giuseppe.

Domenico VENEZIANO, in full DOMENICO DI BARTOLOMEO DA VENEZIA (active by 1438—d. May 15, 1461, Florence [Italy]), early Italian Renaissance painter, one of the founders of the 15th-century Florentine school of painting.

Domenico was probably first trained in the International Gothic manner in Venice, where it is likely he saw paintings by northern European artists. He settled in Florence about 1439 and, except for brief periods, worked there until his death.

Two signed works by Domenico survive. The first, a much-damaged fresco of the Virgin and Child enthroned and two damaged heads of saints (National Gallery, London), formed part of the "Carneseccchi Tabernacle" and may have been the first work Domenico executed in Florence. Its accurate perspective and the sculptural quality of the figures suggest he was influenced by Masaccio. The second work is an altarpiece for the Church of Santa Lucia dei Magnoli, usually called the Magnoli, or St. Lucy, altarpiece, which was probably painted about 1445. The central panel, the Virgin and Child with four saints (Uffizi, Florence), is one of the outstanding paintings produced in Florence in the middle of the 15th century. It is remarkable for the soft contours of its figures, its fresh and delicate palette, its mastery of light, and its precise and subtle space construction. The five panels of the predella are now dispersed. "The Annunciation" (Fitzwilliam Museum, Cambridge, Eng.) is the most successful of Domenico's experiments in rendering outdoor light: the pale morning light fills and defines the space of the court-

SCALA—Art Resource

yard, and the cool light on the broad plane of white wall heightens the sense of moment and loneliness in the two figures.

A tondo of the "Adoration of the Magi" (Staatliche Museen Preussischer Kulturbesitz, Berlin) is of uncertain date. It combines gay colour with careful realism and has an expansive and accurately drawn landscape background.

Domenico's two profile portraits of Matteo and Michele Olivieri (National Gallery of Art, Washington, D.C., and Rockefeller Collection, New York City) are in the tradition of Pisanello.

Domesday Book, the original record or summary of William I the Conqueror's survey of England. By contemporaries the whole operation was known as "the description of

England," but the popular name Domesday—i.e., "doomsday," when men face the record from which there is no appeal—was in general use by the mid-12th century. The survey, in the scope of its detail and the speed of its execution, was perhaps the most remarkable administrative accomplishment of the Middle Ages.

The survey was carried out, against great popular resentment, in 1086 by seven or eight panels of commissioners, each working in a separate group of counties, for which they compiled elaborate accounts of the estates of the king and of his tenants in chief (those who held their land by direct services to him). From these documents the king's clerks compiled a summary, which is Domesday Book.

Domesday Book covers all of England except the northern areas. Though invariably called Domesday Book, in the singular, it in fact consists of two volumes quite different from each other. Volume I (Great Domesday) contains the final summarized record of all the counties surveyed except Essex, Norfolk, and Suffolk. For these three counties the full, unabbreviated return sent in to Winchester by the commissioners is preserved in volume II (Little Domesday), which, for some reason, was never summarized and added to the larger volume.

Several related documents survive, one of which is the Exon Domesday, an early draft of the return for the circuit comprising the counties of Somerset, Dorset, Wiltshire, Devon, and Cornwall.

From yet another related document, the *Inquisitio comitatus Cantabrigiensis* ("The Inquisition of the County of Cambridge"), a very early draft of the Cambridgeshire material, the actual procedure followed by the commissioners is revealed. Their method was that of the sworn inquest, by which answers were given to a long list of definite questions. Formal sessions were apparently held in the chief county town, and the facts were supplied by the sheriff, the barons, and their subtenants and by representatives from each hundred (or subsidiary division of the county) and from every village.

The procedure was thus strictly geographic, material being collected by shires, hundreds, and villages. But before being sent to the royal court at Winchester the material for each county was regrouped under the names of the king and his tenants in chief, thus recognizing the new Norman conception of a feudal society based on the honour or barony, a complex of estates that were treated as a unit even if not adjacent.

Volume I thus gives, under each county heading, a roll of the holders of land, from the king to the humblest tenant in chief. Their fiefs are described consecutively and consist of long lists of manors, with the names of their holders in 1066 and 1086, their dimensions and plowing capacity, the number of agricultural workers of various sorts, their mills, fishponds, and other amenities, and finally their values in pounds.

For most English villages and towns (but not, unfortunately, London and Winchester, for which no Domesday records survive), Domesday is the starting point of their history. For historians of Anglo-Norman England, the survey is of immeasurable importance.

Domesday Book is kept at the Public Record Office in Chancery Lane, London, where it is on view to the public.

domestic cat (species *Felis catus*), also called HOUSE CAT, domesticated member of the family Felidae, order Carnivora.

A brief treatment of the domestic cat follows. For full treatment, see MACROPAEDIA: Cats, Domestic.

The domestic cat retains many of the characteristics of larger wildcats. Its eyes are extremely sensitive to light. Its triangular ears rotate rapidly to identify the source of a sound and can respond to frequencies of up to 25,000 vibrations per second. Domestic cats also retain the main specializations of all cats toward predation—teeth and strong, sharp, retractile claws. The canine teeth stab and hold prey, and the sharp-edged molars function as scissors. The incisors and premolars are hardly functional and do not meet when the mouth is closed.

Domestic cats vary a great deal from larger cats in coat as well as size. Male domestic cats may reach 71 cm (28 in.), but 51 cm (21 in.) is a more usual length for females. An alley cat (*i.e.*, a nonpedigreed cat) may weigh up to 13 kg (28 lb), but the weight of most domestic cats varies from 2.5 to 4.5 kg (6 to 10 lb). Most house cats, including the Siamese and Abyssinian, are short-haired, but the Persian has a long, thick coat and mixed breeds vary. A British breed, the Rex, has a curly coat. Domestic cats are usually black, yellow, gray, tabby (dark stripes or swirls on a lighter background), white, or a mixture of these. Tortoiseshell marking—a piebald mix of white, black and yellow—is normally found only in females. The rare males born with this colour pattern are almost invariably sterile. Siamese cats are distinguished by pale ground colour with darker points (face-mask, ears, feet, and tail). Blue eyes are usually associated with a dilution in coat colour, as in the Siamese. Blue-eyed white cats are frequently deaf.

The earliest authenticated record of the domestication of the cat dates from 1500 BC in ancient Egypt, although the cat was proclaimed to be sacred in that country about 1,000 years earlier. The actual domestication of cats probably came about when the Egyptians noticed that cats protected their granaries from rodents. The Egyptians worshipped a goddess with a cat's head (Bast), and thousands of mummified cats have been found.

Domestic cats spread to other cultures and were common to Greece and China by 500 BC, and known in India by 100 BC. The first record of domestic cats in Britain dates to AD 936, when a law was passed in Wales for their protection. By the mid-18th century domestic cats were present in the United States.

Throughout the ages the cat has been associated with several superstitions and with witchcraft. They often have been regarded as witches' familiars, and black cats have been regarded generally as unlucky omens.

Cats are ideal house pets and are easily house-trained. Their size and agility enable them to adjust quickly to small households. They are able to produce three litters in one year. Estrus or heat may occur up to five times a year, during which the female (queen) calls, or yowls, to alert the male (tom). Gestation is about 63 days and an average litter contains four kittens, which are born blind, deaf, and helpless. A simple operation, called spaying, neutering, or fixing, removes a cat's ability to reproduce.

domestic pigeon (*Columba livia*), bird of the family Columbidae (order Columbiformes) that was perhaps the first bird tamed by man. Figurines, mosaics, and coins have portrayed the domestic pigeon since at least 4500 BC (Mesopotamia). From Egyptian times the pigeon has been important as food. Its role as messenger has a long history. Today it is an important laboratory animal, especially in endocrinology and genetics.

Throwbacks among modern domestic pigeons indicate a common ancestor, the rock dove. This tendency is clearly seen in street pigeons in cities everywhere. Many are white,

Domestic pigeon (*Columba livia*)
Lilyan Simmons—EB Inc

reddish, or checkered like some of their cousins in racing-pigeon lofts, but most are somewhat narrow-bodied and broad-billed replicas of the blue-gray ancestral form. Street pigeons nest year-round, on buildings and beneath bridges, where they may be a nuisance with their droppings and transmission of disease. These hardy birds may live 35 years.

The three main kinds of domestic pigeons are fliers, fancy breeds raised chiefly for show, and utility breeds, which produce squabs for meat—nestlings taken when 25 to 30 days old and weighing 350 to 700 grams ($\frac{3}{4}$ to $1\frac{1}{2}$ pounds). Utility breeds are known as dual-purpose birds if they are bred to exhibition standards.

Pigeon-raising is a worldwide hobby, and business as well. National preferences are evident; *e.g.*, in England for birds of highly standardized appearance and bearing ("form pigeons"), in Germany for birds that have unusual markings ("colour pigeons"), in Belgium for racing pigeons, and in the United States for dual-purpose breeds. Hundreds of varieties of complicated lineage represent centuries of development. *See also* fowl.

domestic service, the employment of hired workers by private households for the performance of tasks such as housecleaning, cooking, child care, gardening, and personal service. It also includes the performance of similar tasks for hire in public institutions and businesses, including hotels and boarding houses.

In ancient Greece, Rome, and various other early civilizations, domestic service was performed almost exclusively by slaves. In medieval Europe, serfs provided much of the necessary labour force. Domestic service remained closely linked to servility even in subsequent ages, as for example, in colonial America and the pre-Civil War South, where the use of indentured servants and black slaves prevailed. By the 1870s, however, domestic servants had become wage earners in the United States and in most European countries.

Domestic service, as an occupation, reached its height in Victorian England. The great households of the royalty and gentry employed large numbers of servants of both sexes. The elaborate hierarchy of positions afforded ample opportunity for advancement. A man could work his way up from groom to valet and then on to butler or even steward. Similarly, a woman could rise from scullery maid to cook or from chambermaid to housekeeper. In general, stewards and housekeepers had their own private servants. Households of lesser, though well-to-do, families often had in their employ a staff of six or more servants, including a lady's maid, nanny, and butler.

The number of people in paid domestic work increased dramatically throughout the late 19th century in most European countries. The United States experienced a similar situation, which continued into the early 1900s and was largely due to the growing number of middle- and upper-class families that wanted and could afford household help. The arrival of a great many unskilled immigrants who

could find no other form of employment contributed this growth.

Since 1921 domestic service has become a steadily declining occupation in the United States and, to a large extent, in most western European countries as well. This trend has been attributed to various factors, including a levelling of social classes; the low status of domestic work; increased job opportunities for women in business and industry after World War II; and the proliferation of household labour-saving devices and comparatively less expensive outside services, such as laundries, day-care centres, and convalescent homes. Although domestic servants are not covered by minimum wage legislation, increases in the legal minimum wage and the coverage of most domestic workers by social security and workers' compensation programs have raised the cost of domestic service considerably.

domestic shorthair, also called **BRITISH SHORTHAIR**, breed of domestic cat often referred to as a common, or alley, cat; a good show animal, however, is purebred and pedigreed and has been carefully bred to conform

Domestic shorthair cat
John Gajda—EB Inc

to a set standard of appearance. The domestic shorthair is required by show standards to be a sturdily built cat with strong-boned legs and a round head with round eyes and ears that are rounded at the tips. The coat must be short and may be any of the colours recognized for the longhair (*q.v.*), or Persian. Some colours, such as blue cream, are infrequently found in shorthairs; others, such as the tabby colours (silver, brown, blue, and red), are commoner. In Britain, the shorthair is called the British shorthair to distinguish it from other breeds classified as foreign shorthairs.

Although the alley, or common, cat may resemble a pedigreed shorthair, it is not a purebred animal; rather, it is a combination of breeds and may differ considerably in build and coat from the purebred shorthair.

domestic system, also called **PUTTING-OUT SYSTEM**, production system widespread in 17th-century western Europe in which merchant-employers "put out" materials to rural producers who usually worked in their homes but sometimes laboured in workshops or in turn put out work to others. Finished products were returned to the employers for payment on a piecework or wage basis. The domestic system differed from the handicraft system of home production in that the workers neither bought materials nor sold products. It undermined the restrictive regulations of the urban guilds and brought the first widespread industrial employment of women and children. The advantages to the merchant-employer were the lower wage costs and increased efficiency due to a more extensive division of labour within the craft.

The system was generally superseded by employment in factories during the course of the Industrial Revolution but was retained in the 20th century in some industries, notably the watchmaking industry in Switzerland, toy manufacturing in Germany, and numerous industries in India and China.

domestic tragedy, drama in which the tragic protagonists are ordinary middle class or lower class individuals, in contrast to Classical and Neoclassical tragedy, in which the protagonists are of kingly or aristocratic rank, and their downfall is an affair of state as well as a personal matter. The earliest known examples of domestic tragedy are three anonymous late Elizabethan dramas: *Arden of Feversham* (c. 1591), the story of the murder of Mr. Arden by his wife and her lover and their subsequent execution; *A Warning for Faire Women* (1599), which deals with the murder of a merchant by his wife; and *A Yorkshire Tragedy* (c. 1606), in which a father destroys his family. To these may be added Thomas Heywood's less sensational but no less tragic *Woman kille With Kindnesse* (1603). Domestic tragedy did not take hold, however, until reintroduced in the 18th century by George Lillo with *The London Merchant, or the History of George Barnwell* (1731). The popularity of this sordid drama of an apprentice who murders his uncle-guardian influenced domestic tragedy in France and Germany, where the dramatist and critic G.E. Lessing, in his *Hamburgische Dramaturgie* (1767–68), paved the way for its critical acceptance.

Bourgeois tragedy found its mature expression in the plays of Henrik Ibsen toward the end of the 19th century. In earlier domestic dramas by other playwrights the protagonists were sometimes villains and at other times merely pathetic, but the bourgeois heroes of Ibsen's *Brand* (1866), *Rosmersholm* (1886), *Master-Builders* (1892), and *When We Dead Awaken* (published 1899) are endowed with some of the isolated grandeur of the heroes of classical tragedy.

A tragedy on a humbler social level than that of the middle class, *Woyzeck*, was written as early as 1836 by the German dramatist Georg Büchner. Its hero, a poor soldier and former serf, is so reduced in status he finds employment as a doctor's guinea pig. Yet the work has a shattering tragic impact and bears out the precept stated by another German tragic dramatist of the 19th century, Friedrich Hebbel: "One need only be a man, after all, to have a destiny." *Woyzeck* was well in advance of its time; lower class tragedy did not come to the fore until the turn of the 20th century with such works as Gerhart Hauptmann's *Die Weber* (1892; "The Weavers") and *Rose Bernd* (1903). Other outstanding examples are Eugene O'Neill's *Long Day's Journey into Night* (1956) and Arthur Miller's *Death of a Salesman* (1949).

To make the best use of the Britannica, consult the INDEX first

domestication, the process of hereditary reorganization of wild animals and plants into domestic and cultivated forms according to the interests of people. In its strictest sense it refers to the initial stage of human mastery of wild animals and plants. The fundamental distinction of domesticated animals and plants from their wild ancestors is that they are created by human labour to meet specific requirements or whims and are adapted to the conditions of continuous care and solicitude people maintain for them.

Domestication has played an enormous part in the development of mankind and its material culture. It has resulted in the appearance of agriculture as a special form of animal and plant production. It is precisely those animals and plants that became objects of agricultural activity that have undergone the greatest changes when compared with their wild ancestors.

The first attempts at domestication of animals and plants apparently were made in the Old World by peoples of the Mesolithic Pe-

riod. The tribes that engaged in hunting and in gathering wild edible plants made attempts to domesticate dogs, goats, and possibly sheep as early as 9000 BC. It was not until the Neolithic Period, however, that primitive agriculture appeared as a form of social activity, and domestication was well under way. Although the great majority of domesticated animals and plants that still serve man were selected and developed during the Neolithic Period, a few notable examples appeared later. The rabbit, for example, was not domesticated until the Middle Ages; the sugar beet came under cultivation as a sugar-yielding agricultural plant only in the 19th century; and mint became an object of agricultural production as recently as the 20th century. Also in the 20th century, a new branch of animal breeding was developed to obtain high-quality fur.

Domestication of vegetatively reproducing plants, such as those with tubers, probably preceded domestication of the seed plants—cereals, legumes, and other vegetables. Some plants were domesticated for the strong fibres in their stalks, which were used for such purposes as making fishing nets. Hemp, one of the most ancient plants domesticated in India, is an example of a multipurpose plant: oil is obtained from its seeds, fibres from its stalk, and the narcotic hashish from its flowers and leaves.

Some plants were domesticated especially for the production of narcotics; such a plant is tobacco, which was probably first used by American Indian tribes for the preparation of a narcotic drink and only later for smoking. The opium poppy is another example of a plant domesticated solely for a narcotic. Beverage plants of many kinds were discovered and cultivated, including tea, coffee, and cola. Only when humans reached a sufficiently high level of culture did they begin to domesticate to fulfill aesthetic requirements for the beautiful and the bizarre in both plants and animals.

The specific economic application of domesticated animals did not appear at once. Dogs probably accompanied hunters and helped them hunt wild animals; they probably also guarded human settlements and warned the inhabitants of possible danger. At the same time, they were eaten by humans, which was probably their main importance during the first stages of domestication. Sheep and goats were also eaten in the initial stages of domestication but later became valuable for producing the commodities of milk and wool.

The principal aim of cattle breeding in ancient times was to obtain meat and skin and to produce work animals, which greatly contributed to the development of agriculture. Cattle, at the initial stages of domestication, produced a small amount of milk, sufficient only to rear their calves. The development of high milk yield in cows with their breeding especially for milk production is a later event in the history of domestication.

The first domesticated horses were also used for meat and skin. Later the horse played an enormous role in the waging of war. Peoples inhabiting the Middle East in the 2nd millennium BC used horses in chariot battles. With time the horse began to be used as transportation. In the 1st millennium BC carts appeared, and the horses were harnessed to them; other riding equipment, including the saddle and the bit, seems to have appeared in later centuries.

The donkey and the camel were used only for load transport and as means of conveyance; their unpalatability ruled out their use as a preferred food.

The first domesticated hens perhaps were used for sport; cockfighting was instrumental in bringing about the selection of these birds for larger size. Cocks later acquired religious significance. In Zoroastrianism the cock was associated with protection of good against evil and was a symbol of light. In ancient Greece

it was also an object of sacrifice to gods. It is probable that egg production of the first domesticated hens was no more than five to ten eggs a year; high egg yield and improved meat qualities of hens developed at later stages of domestication.

Early domestication of the cat was probably the result of the pleasure experienced from keeping this animal. The cat's ability to catch mice and rats was surely another reason that impelled people to keep cats at home. In ancient Egypt the cat was considered a sacred animal.

Some animals were domesticated for utilitarian purposes from the very beginning. Here belongs, first of all, the rabbit, whose real domestication was carried out from the 6th to the 10th centuries AD by French monks. The monks considered newborn rabbits fish and ate them when the church calendar indicated abstinence from meat.

For the sake of honey, the bee was domesticated at the end of the Neolithic Period. Honey has played an enormous role in human nutrition since ancient times; it ceased being the sole sweetening agent only about 200 years ago. Bees also provided wax and bee venom, which was used as medicine. Bees were used also, to a limited extent, in warfare, hives being thrown among enemy troops to rout them.

To obtain silk, the silkworm was domesticated in China no later than 3000 BC, and by 1000 BC the technology of silkworm breeding and raising had been thoroughly documented.

Shepherdy and nomadic animal breeding, which determined the social and economic organization and the way of life of some peoples to a great extent, appeared at later stages of human development, after the accumulation of a large number of domestic animals. Rudiments of nomadic animal breeding in Eurasia appeared no earlier than 1000 BC, considerably after the domestication of animals took place.

The process of domestication in the New World took place somewhat later than in the Old World and independently of the latter, since humans first appeared in the New World only during the Pleistocene, long after settlement of the Old World.

Traditionally, the main criteria for judging relationships between domestic or cultivated organisms and wild ancestors are similarities of structure and function, but cytogenetical examinations, particularly comparisons of chromosomes and chromosome sets, also are adding to the knowledge of the origins of domesticated organisms. With animals, morphological and biochemical (*i.e.*, blood typing) studies are made.

During the 10,000 or 11,000 years that have passed since the beginning of domestication, the animals and plants that humans have selected as useful to them have undergone profound changes. The consequences of domestication are so great that the differences between breeds of animals or varieties of plants of the same species often exceed those between different species under natural conditions.

The most important consequence of domestication of animals consists of a sharp change in their seasonal biology. The wild ancestors of domesticated animals are characterized by strict seasonal reproduction and molting rhythms. Most domesticated species, on the contrary, can reproduce themselves at almost any season of the year and molt little or not at all. No less characteristic are the changes that occur in plants as a result of domestication. Their structure and general appearance may be drastically changed.

The elementary genetic mechanism that draws the recessive genes out from the cover of the wild genotype of the natural species also

brings about the first domestication-dependent changes and the initial differentiation of a wild species into types that can serve as the basis for breed formation. Nature, in effect, has a store of various types and forms hidden as recessive mutations in every natural population of wild animals and plants. It is this accumulated mutation pool that is exploited by humans in breeding. Such interference, called artificial selection, plays a truly creative role in the formation of modern animal breeds and plant varieties to suit human needs.

Artificial selection differs considerably from natural selection, which creates stabilized biological systems that ensure the development of a normal, or so-called wild, phenotype; *i.e.*, an organism containing a wealth of properties that preadapt it to a wide variety of environmental conditions and ensure continuation of the species. Artificial selection breaks down precisely these stabilized systems, thereby creating gene combinations that could not survive in nature and providing a range of new possibilities.

Domett, Alfred (b. May 20, 1811, Camberwell, Surrey, Eng.—d. Nov. 2, 1887, London), writer, poet, politician, and prime minister of New Zealand (1862–63), whose idealization of the Maori in his writings contrasts with his support of the punitive control of Maori land.

Following study at Cambridge and being admitted to the bar, Domett travelled to New Zealand (1842) and, after a half-hearted attempt at farming, devoted his time to journalism and public affairs. He became editor of the *Nelson Examiner* (1843) and began his involvement with the administration of settler land by accepting appointment by Governor, later Prime Minister, Sir George Grey (*q.v.*) as member of the legislative council (1846), as colonial secretary for the province of New Munster (1848), and as civil secretary to the general government. Elected from Nelson to the House of Representatives (1855), he also accepted appointment as commissioner of crown lands (1856). Re-elected to Parliament (1860), Domett was asked to form a ministry by Governor Grey at a time of crisis in the administration of Maori land (1862). Domett's government maintained that the responsibility for Maori affairs belonged to the British government along with the cost of military troops to enforce control of the Maori. Another war ensued, and Domett's government ended (1863). He accepted appointments as secretary for lands (1863) and registrar-general of lands (1865) and also joined the legislative council, thus combining paid service with an advisory position once again. In 1870 an act was passed disqualifying any person holding office from accepting paid appointment by the crown, but Domett was specifically exempted; his talents as an administrator of land law were indispensable. He retired to England (1871) and wrote and published several works, including the romantic narrative epic *Ranolf and Amohia* (1872).

domeykite, a copper arsenide mineral (formulated Cu_3As) that is often intergrown with algodonite, another copper arsenide. Both are classified among the sulfide minerals, although they contain no sulfur. They occur in Chile, in Keweenaw County, Mich., and in other localities. Domeykite crystallizes in the isometric system. For detailed physical properties, see sulfide mineral (table).

domicile, in law, a person's dwelling place as it is defined for purposes of judicial jurisdiction and governmental burdens and benefits. Certain aspects of a person's legal existence do not vary with the state he happens to be in at any given moment but are governed by a personal law that follows him at all times.

In Anglo-American countries, where common law applies, one's personal law is that of his domicile; in civil-law countries (*e.g.*, those of Europe and Latin America) it is often that of his nationality.

The place in which a man is domiciled has judicial jurisdiction over him—*i.e.*, a case can be tried against him in its courts, even though he happens to be outside its borders at the time he is summoned. So far as governmental burdens and benefits are concerned, only the place of a man's domicile can impose an inheritance tax upon all of his intangibles. The law of a person's domicile determines the validity of his will with respect to personal property or decides how such property shall be distributed if he dies without a will. The law of a man's domicile also may play a part in determining the legitimacy of his birth and the validity of his marriage.

It is a fundamental principle in Western law that every person must have a domicile at all times. A domicile is not lost until another domicile has been acquired, and a person cannot have more than one domicile at a time for the same purpose. The burden of proof is upon him who asserts that there has been a change of domicile. It is commonly said that there are three kinds of domicile: domicile of origin; domicile of choice; and domicile by operation of law.

At birth a person acquires a domicile of origin, almost always that of his father. If the father is deceased or the child is illegitimate, the domicile is that of his mother.

Most people possess a domicile of choice, usually established by voluntary physical presence at the place where domicile is claimed; presence by reason of compulsion, as imprisonment, is not sufficient. If a person claims a place as a home but is not living there, he must prove intent to make the place a home.

Persons who lack the legal capacity to acquire a domicile of their own possess domicile by operation of law. The prime example is minor children whose domicile is that of the father. The domicile of a married woman is that of her husband as long as she lives with him.

Complications arise because statutes rarely use the word domicile but refer instead to residence (or, in some statutes, abode). Residence, in such a context, usually bears the same meaning as domicile. But on occasion it may mean something else, such as a well-settled physical connection with the state without bearing toward it the requisite attitude of mind that one intends to reside there. Sometimes residence means something more than domicile, namely, domicile in a place plus physical presence there during a specified period of time. Residence when used in a statute means, in any event, a far closer relationship with a state than mere physical presence there. As in the case of domicile, a residence, once it has been acquired, is not lost by a temporary absence from the state. In contrast to domicile, a man may have more than one residence at a time.

dominance, in genetics, greater influence by one of a pair of genes (alleles) that affect the same inherited character. If an individual pea plant with the alleles T and t (T = tallness, t = shortness) is the same height as a TT individual, the T allele (and the trait of tallness) is said to be completely dominant; if the Tt individual is shorter than the TT but still taller than the tt individual, T is said to be partially or incompletely dominant; *i.e.*, it has a greater influence than t but does not completely mask the presence of t , which is said to be recessive.

In ecology, the term dominance is used to describe a species of animal or plant that exerts the most influence on the other species of its community because its members are the most abundant or the largest. In animal behaviour, a ruling animal in a social grouping

is described as dominant. See also recessiveness.

dominance hierarchy, a form of animal social structure in which a linear or nearly linear ranking exists, with each animal dominant over those below it and submissive to those above it in the hierarchy. Dominance hierarchies are best known in social mammals, such as baboons and wolves, and in birds, notably chickens (in which the term peck order or peck right is often applied).

In most cases the dominance hierarchy is relatively stable from day to day. Direct conflict is rare; an animal usually steps aside when confronted by one of higher rank. Temporary shifts occur; for instance, a female baboon mated to a high-ranking male assumes a high rank for the duration of the pair bond. An individual weakened by injury, disease, or senility usually moves downward in rank. See also submissive behaviour.

dominant, in music, fifth tone of the diatonic scale (which has five whole tones and two semitones), *e.g.*, G in the scale of C. In the tonality of Western music of the 17th to 19th century, the dominant was particularly important, for it stood in strongest relation to the tonic, or keynote (C in the key of C).

Chords based on the dominant had a strong tendency to move to the tonic chord, and the key built upon the dominant was most strongly related to the tonic key. The relation between dominant and tonic was exploited in musical forms such as the sonata.

Domingo DE GUZMÁN, SANTO: see Dominic, Saint.

Domingo, Plácido (b. Jan. 21, 1941, Madrid), Spanish-born operatic tenor whose resonant, powerful voice, imposing physical stature, good looks, and dramatic ability made him one of the most popular tenors of the second half of the 20th century.

Domingo's parents were noted performers in zarzuela, a form of Spanish light opera. He grew up in Mexico, where he studied piano at the National Conservatory of Music. In 1961 he made his operatic debut in Mexico City and then went to Dallas, Texas, to perform in its opera company. From 1962 to 1965 he was a resident performer at Tel Aviv's Hebrew National Opera. He made his debut at the New York City Opera in 1965, at the Metropolitan Opera House in New York City in 1968 (subsequently becoming a regular performer there), and at La Scala in Milan in 1969.

A prolific and versatile performer, Domingo made numerous recordings and several film versions of operas, and he ventured into popular music as well. His autobiography, *My First Forty Years*, was published in 1983.

Domínguez Bastida, Gustavo Adolfo (Spanish writer): see Bécquer, Gustavo Adolfo.

domini: see dominus.

Dominic, SAINT, Spanish in full SANTO DOMINGO DE GUZMÁN (b. c. 1170, Caleruega, Castile—d. Aug. 6, 1221, Bologna, Romagna; canonized July 3, 1234; feast day August 8), founder of the Order of Friars Preachers (Dominicans), a religious order of mendicant friars with a universal mission of preaching, a centralized organization and government, and a great emphasis on scholarship.

Early life and career. Domingo de Guzmán was born in Castile, possibly a year or two later than 1170, the traditional date. His father was lord of the manor in the village, and his mother was also from the local nobility. He studied at Palencia and then joined the canons regular (a religious community attached to the cathedral of a diocese) of Osma about 1196, and he became subprior, or assistant to the superior, a few years later. In 1203, Diego, bishop of Osma, was sent on a royal mission abroad and took Dominic with him.

This journey first made Dominic aware of the threat posed to the church in the south of France by the Albigensian heretics, or Cathari, who were reviving and developing the Manichaean teaching that two supreme beings, Good and Evil, dominate spirit and matter respectively, so that whatever concerns the body—such as eating, drinking, procreation, and the possession of worldly goods—is essentially evil, and the ideal is the renunciation of these things and even of life itself.

St. Dominic, detail of a panel by the school of Messina (?), 15th century; in the Museo Archeologico Nazionale, Palermo, Italy
Anderson—Alinari from Art Resource

Thus, there arose among them a caste of the "perfect," who led a life of great austerity, while ordinary people were regarded as reprobates. A regularized Albigensian hierarchy had come into existence, and local feudal lords, especially the count of Toulouse, supported the Albigenses. Pope Innocent III had launched a mission to preach against the heresy.

On a second journey Dominic and the bishop visited the pope, who refused their request to preach to the pagans, so they returned to France. In 1206 the papal legates and preachers, depressed at the failure of their mission, consulted the bishop and Dominic, who reasoned that the heretics would be regained only by an austerity equal to their own; the preachers must tramp the roads barefoot and in poverty. This was the birth of Dominic's "evangelical preaching." An important part of his campaign was the establishment of a convent of nuns at Prouille, formed in 1206 from a group of women converted from the heresy.

In 1208 the papal legate, Peter de Castelnau, was murdered by an emissary of the Count of Toulouse. The pope called upon the Christian princes to take up arms. The leader on the papal side was Simon de Montfort, a subject of the king of France. The Albigensian leader was Raymond VI, count of Toulouse, an opponent of the king of France and brother-in-law of King John of England, lord of neighbouring Aquitaine. Dominic's work, though confined to the Prouille area, continued, and six others eventually joined him. Meanwhile, the civil war dragged on until Simon's victory at Muret in 1213. The Catholic party entered Toulouse, and Dominic and his friends were welcomed by the bishop, Foulques, and established as "diocesan preachers" in 1215.

Foundation of the Dominicans. From Foulques's charter in that year, Dominic's design for an order devoted to preaching developed rapidly. A characteristic concern was for

the theological formation of his men, whom he therefore took to lectures given at Toulouse by an Englishman, Alexander Stavensby. Still in 1215, he went to Rome with Foulques (bound for the Fourth Lateran Council) to lay his plans before the pope, who, however, recommended adoption of the rule of one of the existing orders. It was, perhaps, at this time that Dominic met Francis of Assisi (though the meeting may not have taken place until 1221), and the friendship of the two saints is a strong tradition in both the Franciscan and the Dominican orders. In the summer of 1216 Dominic was back at Toulouse conferring with his companions, now 16 in number. This meeting has been called the *capitulum foundationis* ("chapter, or meeting, of foundation"). The rule of St. Augustine was adopted, as well as a set of *consuetudines* ("customs"), partly based on those of the canons regular, concerning the divine office, monastic life, and religious poverty; these are still the core of Dominican legislation. In July, Innocent III died, and it was from his successor, Honorius III, that Dominic, once more in Rome, finally received on Dec. 22, 1216, formal sanction of his order.

The order was now an established body within the church, and Dominic returned to Toulouse. On Aug. 15, 1217, he sent his men to Paris and to Spain, leaving two each at Toulouse and Prouille, while he and another went to Bologna and Rome. He placed his two principal houses near the universities of Paris and Bologna and decided that each of his houses should form a school of theology. This at once determined the capital role that the Dominicans would play in university studies. In setting up his houses in the larger cities, especially in those that were teaching centres, he involved his order in the destiny of the medieval urban movement.

Dominic was gifted in being able to conceive his ideal, to form his men to that ideal, and then to trust them completely. His leadership had great clarity of vision (even to the geographical distribution of his forces and precise details of legislation), firmness of command, and certainty of execution. At the same time it was said of him that his gentleness was such that anyone who came to speak to him, even for reproof, went away happier.

The rest of Dominic's life was spent either in Rome, where he was given the Church of San Sisto, or traveling. In 1218-19 he made a great tour (3,380 miles entirely on foot) from Rome to Toulouse and Spain and back, via Paris and Milan, and in 1220 a tour of Lombardy. Everywhere his communities were growing, and he planned many new foundations covering the key points of France and northern Italy. In Rome the pope gave him the delicate task of reforming various groups of nuns, whom he finally gathered at San Sisto in 1221, when the men moved to Santa Sabina, which is still the residence of the master general of the order.

At Pentecost in 1220 the first general chapter of the order was held at Bologna, and a system of democratic representative government was devised. At the second general chapter, held on Pentecost in 1221, also at Bologna, the order was divided geographically into provinces. After a visit to Venice in 1221, Dominic died at Bologna. (S.Bh./Ed.)

The best biography in English is Bede Jarrett, *Life of Saint Dominic (1170-1221)*, 2nd ed. (1934, reissued 1964). William A. Hinnebusch, *The History of the Dominican Order*, vol. 1 (1966), details Dominic's life and the development of the order.

Dominic OF THE MOTHER OF GOD: see Barberi, Domenico.

Dominica, officially COMMONWEALTH OF DOMINICA, island republic of the Lesser An-

tilles in the Caribbean Sea. It is situated between the French islands of Guadeloupe to the north and Martinique to the south; on its eastern shore is the Atlantic Ocean. The capital is Roseau. Dominica covers an area of 290 square miles (750 square km) and is some 29 miles (47 km) long and 16 miles (26 km) wide. The population in 1990 was estimated to be 80,500.

For information about regional aspects of Dominica, see MACROPAEDIA: West Indies.

For current history and for statistics on society and economy, see BRITANNICA BOOK OF THE YEAR.

Dominica

The land. Dominica is a mountainous island of volcanic origin, and its main physical feature is a high, forest-clad range that runs from north to south, culminating in Mount Diablotin (4,747 feet [1,447 m]). It is broken midway through its north-south length by a plain, which is drained by the Layou River, flowing west. There are numerous other rivers and streams, but most are unnavigable. Dominica has a warm year-round tropical climate with temperatures that range from 78° F (26° C) to 90° F (32° C). Rainfall on the island is extremely heavy, averaging 250 inches (6,350 mm) in the mountains and 70 inches (1,780 mm) along the coast.

Dominica's volcanoes are probably extinct, but Boiling Lake in the south and a number of thermal springs provide evidence of some continuing volcanic activity. The volcanic basis of the island has provided it with a rich soil, and dense tropical plant growth has developed in places into rain forest.

Bird life on the island is especially rich, with 135 species, including parrots, the blue-headed hummingbird, and the trembler, a thrush whose courtship involves a rapid quivering movement. There are also iguana, opossum, the agouti, the boa constrictor, and many species of bat.

The people. Most of the people of Dominica are of African or of mixed African and European descent. Other peoples of the island include small groups of European and Syrian ancestry and the main surviving community of Caribs, who were the Pre-Columbian inhabitants of the Caribbean islands. The first European settlers of Dominica were mainly French, and the most common language spoken is a French patois. English, however, is the official language and is also widely used. The people are mainly Roman Catholics, but there are long-established Protestant denominations as well. The largest city is Roseau. Dominica grew rapidly during the 1970s, mainly as the result of a drop in its death rate and despite steady out-migration. Hurricane David resulted in a massive exodus in 1979, but the migratory trend reversed in the 1980s. The population of Dominica is relatively young, with two-fifths of the people under 15 years of

age. Most of the islanders live in rural areas and work in agriculture.

The economy. Dominica is one of the poorest of the Caribbean nations. The performance of the economy through the 1970s was characterized by declining production and reduced private investment and was complicated by devastating hurricanes that struck the island in 1979 and 1980. The economy had recovered by the mid-1980s, in part through foreign assistance from such sources as the United States, the United Kingdom, Canada, and the United Nations. Although the gross national product (GNP) is growing much more rapidly than the population, the GNP per capita remains relatively low.

Agriculture remains the most important sector of the economy, in terms of both contribution to the GNP and employment. The banana crop provides the country with its chief agricultural product and its main export. Farms also produce grapefruit, limes, oranges, and vegetables. Coconuts are important and have given rise to industries that produce copra, coconut oil and fats, soap, and detergents. Other industries that derive from agricultural products are those producing fruit juices and rum. Handicrafts are important, and a local industry makes cigarettes from imported tobacco. Pumice, the country's only commercial mineral resource, is mined. There is some livestock raising and a small commercial fishing industry. Hurricane David in 1979 destroyed many of the island's fishing boats, and recovery has been slow.

The Industrial Development Corporation was established in 1974 to promote industrial expansion. Exports include, in addition to bananas, coconut oil and fruit juices. Imports are largely made up of foods, metals, and manufactured goods. The United States is the major import source, and the United Kingdom is the major export destination.

Dominica's rich tropical environment and mild climate provide the island nation with the potential for a thriving tourist industry, but tourism has been slow to develop. Tourist trade was enhanced by the establishment in 1975 of Morne Trois Pitons National Park, a unique tropical mountain wilderness.

A number of steamship services call at the deepwater port near Roseau, which was completed in 1976. Portsmouth is the major banana-shipping port. The main airfield is Melville Hall, about 36 miles (58 km) from Roseau. A secondary airfield, Canefield Airport, just 3 miles (5 km) north of Roseau, was opened in 1982. About three-fifths of the nation's road network is paved.

Government and social conditions. Dominica is governed in accordance with the constitution that took effect on independence day, Nov. 3, 1978. It established Dominica as a republic and provided for a Parliament, composed of a president and a House of Assembly, as the chief organ of government. The House is made up of 21 elected representatives, 1 ex officio member, and 9 members, usually called senators, who may be either elected or appointed. Executive power resides in the president, who is elected by the House for a five-year term; he may hold the office for no longer than two terms. The prime minister is appointed by the president to preside over the Cabinet. Dominica is a member of The Commonwealth, the United Nations, the Organization of American States, and the Caribbean Community.

The government is trying to improve social conditions in Dominica, which has serious problems of poverty and underdevelopment. Programs to clear slums and provide more adequate housing are being dealt with through international aid and community efforts. Medical services are provided by the government

through dispensaries, hospitals, and health centres. Intestinal diseases, diabetes, anemia, and sexually transmitted diseases are among the most prevalent health problems on the island.

Primary education is free for children 5 to 15 years of age and is compulsory where practical. Most of the schools are government-run, but a few denominational schools are also in operation. Dominica has several secondary schools. There is a teacher-training college and a branch of the University of the West Indies on the island.

Several newspapers are published locally. There is a government-owned radio station, and television broadcasts are received through a television relay station, which brings programs from Barbados.

History. The earliest known inhabitants of the West Indies were two Amerindian tribes: the Arawaks, who migrated from South America, and the Caribs, who later drove them out. At the time of Columbus' arrival, Dominica was inhabited by the fierce, warlike Caribs, who were at war with the inhabitants of neighbouring islands.

The island received its name from the Latin *dies dominica* ("the Lord's day," or "Sunday"), the day on which Christopher Columbus sighted it in 1493. It remained one of the last islands to be explored by Europeans, because of its steep coastal cliffs and inaccessible mountains. The island's strategic position, however, later caused it to become the centre of a threefold conflict between the Carib Indians, the British, and the French. Control of the island was contested between the British and French until it was ultimately awarded to Britain in 1783. Subsequent hostilities between the settlers and the native inhabitants resulted in the near extinction of the Caribs by war, disease, and deportation.

Dominica's position in the eastern rim of the Caribbean, where the Windward Islands are off to the south and the Leewards to the west, has caused ambiguity in its geographic grouping. At first Dominica was one of the Leeward Islands, part of a British Caribbean government administered from Barbados. In 1671 Dominica, along with several other islands, was separated from Barbados, and in 1771 it was made a separate government. In 1833 it was united with seven other islands under the government of the Leeward Islands; it was a member of the Federation of the Leeward Islands, created in 1871, but was transferred to the Windward Islands in 1940. In 1956, with three other islands, it formed the Territory of the Windward Islands, which in 1958 joined the Territory of the Leeward Islands to form the Federation of the West Indies. In 1967 Dominica, among other islands, became a self-governing state within the West Indies Associated States, retaining complete control of internal affairs while Britain remained responsible for external relations and defense. In 1978 it became independent as the Commonwealth of Dominica.

In August 1979 Hurricane David virtually destroyed the island: nearly 75 percent of the population was homeless, the capital was in ruins, and damage to schools was severe. There was a 60 percent decline in general agricultural production and near total destruction of export crops and timber; all essential services were stopped. Before recovery could get fully underway, another hurricane struck in 1980, bringing additional destruction. Adding to Dominica's problems was a confused political scene, which was complicated by two attempted coups in 1981. Nevertheless, considerable progress was made toward recovery in the 1980s.

Dominica Channel, marine passage in the Lesser Antilles, West Indies, connecting the Caribbean Sea with the open Atlantic Ocean to the east. It flows between the island of

Dominica (north) and the French island and overseas *département* of Martinique (south) and is about 25 miles (40 km) wide.

Dominican, byname BLACK FRIAR, member of ORDER OF FRIARS PREACHERS, also called ORDER OF PREACHERS (O.P.), one of the four great mendicant orders of the Roman Catholic church, was founded by St. Dominic in 1215. Dominic, a priest of the Spanish diocese of Osma, accompanied his bishop on a preaching mission among the Albigensian heretics of southern France, where he founded a nunnery at Prouille in 1206, partly for his converts, which was served by a community of preachers. From this developed the conception of an institute of preachers to convert the Albigensians, which received provisional approval from Pope Innocent III in 1215. Dominic gave his followers a rule of life based on that of St. Augustine and made his first settlement at Toulouse; on Dec. 22, 1216, Pope Honorius III gave formal sanction. The novelty of the institute was the commission to preach Christian doctrine, a task previously regarded as the prerogative and monopoly of bishops and their delegates; a corollary was the obligation of theological study, and, as early as 1218, Dominic sent seven of his followers to the University of Paris.

From the beginning the order has been a synthesis of the contemplative life and the active ministry. The members live a community life; and a careful balance is maintained between democratically constituted chapters, or legislative assemblies, and strong but elected superiors. In contrast to the monastic orders that predated it, the Dominican order was not a collection of autonomous houses; it was an army of priests, organized in provinces under a master general and ready to go wherever they were needed. The individual belonged to the order, not to any one house, and could be sent anywhere at any time about its business; this innovation has served as a model for many subsequent bodies.

Within 40 years of the order's foundation, talented members were concentrated in the schools at Paris, Bologna, Cologne, and Oxford; many eminent masters of the universities took the Dominican habit and became in time regents in the friaries. Originally students of theology only, and with no distinguishing philosophical opinions, they were led by Albertus Magnus and his pupil Thomas Aquinas to a study of the newly available works of Aristotle that had been transmitted to Europe by Muslim scholars and to the integration of philosophy and theology. After a short initial opposition, the system of St. Thomas Aquinas was adopted as official (1278). Meanwhile, the Dominicans pursued their vocation to preaching. In southern France they spoke out against the Albigensians and, in Spain and elsewhere, against the Moors and Jews. They evangelized the non-Christians in northern and eastern Europe, in the lands of the eastern Mediterranean, and in India. When the Inquisition was established, Dominicans were entrusted with its execution. They were among the first and most energetic missionaries in the "expansion of Europe" under the Spanish and Portuguese explorers and later under the French. In modern times they have broadened their preaching apostolate to include work in the fields of radio, television, films, and stage.

The Dominican order has continued to be noted for an unswerving orthodoxy, based upon the philosophical and theological teaching of Aquinas, and has steadfastly opposed novelty or accommodation in theology. The 19th and 20th centuries have witnessed a

tremendous development of congregations of Dominican sisters engaged in teaching, nursing, and a wide variety of charitable works. Some of these congregations, such as the Maryknoll Sisters, are devoted to work in foreign missions.

Dominican Republic, Spanish *REPÚBLICA DOMINICANA*, country of the West Indies, comprising the eastern two-thirds of the island of Hispaniola and several small, adjacent islands. It is situated about 670 miles (1,080 km) southeast of the U.S. state of Florida, between the Atlantic Ocean to the north and the Caribbean Sea to the south. It is the second largest country, after Cuba, in the West Indies. The Dominican Republic is bordered on the west by Haiti (occupying the western third of the island) and is separated from Puerto Rico to the east by a channel called the Mona Passage. The capital is Santo Domingo. Area 18,704 square miles (48,443 square km). Pop. (1993 est.) 7,620,000.

Dominican Republic

A brief treatment of the Dominican Republic follows. For full treatment, see *MACROPAEDIA: West Indies*.

For current history and for statistics on society and economy, see *BRITANNICA BOOK OF THE YEAR*.

The land. The country is generally mountainous, with ranges and hills running from northwest to southeast. The most prominent feature is the Cordillera Central (Central Highlands; average elevation 6,000 feet [1,800 m]), which reaches 10,417 feet (3,175 m) at Duarte Peak, the highest point in the West Indies. The Cibao Valley (140 miles [225 km] long and 14 miles [23 km] wide) in the north-central area is noted for its fertility; the most prosperous region of the country, it produces rice, corn (maize), beans, tobacco, and coffee. The western part of the country is generally dry with large stretches of desert. The Yaque del Norte in the north, the Yaque del Sur in the south, and the Yuna in the east are the main rivers and provide water for irrigation and hydroelectric power. The salt lake of Enriquillo (23 miles [37 km] long and 11 miles [18 km] wide) is the lowest (144 feet [44 m] below sea level) point in the West Indies.

The country has a moderate tropical climate. The annual mean temperature is 77° F (25° C), ranging from 69° F (21° C) in the heart of the central mountains to a high of 82° F (28° C) on the coastal plains; annual precipitation is about 53 inches (1,346 mm), varying from more than 100 inches (2,540 mm) in the northeast to only about 30 inches (760 m) in the west. Tropical storms and hurricanes are a major weather hazard. Dense evergreen forests of pine and hardwood (including mahogany) thrive in the wetter northeast and east, and savanna vegetation and low shrubs are common in the drier west. Much of the eastern savanna is used for sugarcane cultivation and cattle ranching. Herds of wild pigs roam the high mountains, and alligators and flamingos are found near Lake Enriquillo.

The Dominican Republic's mineral resources include bauxite, gypsum, iron ore, nickel, silver, gold, and platinum; the rock salt deposits in the southwest are among the largest in the world. There are also known deposits of sulfur, coal, molybdenum, cobalt, tin, and zinc, as well as petroleum.

The people. Predominantly populated with people of mixed European and African ancestry (mulatto), the Dominican Republic also has small groups of European minorities (including German Jews); a Japanese colony engages in truck farming in the Constanza Valley, and the Chinese particularly have established themselves in the hotel and restaurant industry. During the 19th century many Mediterranean immigrants intermarried with the population. Spanish is the official language, and various European languages are also spoken. Most of the population is Roman Catholic.

Although birth and death rates have declined substantially since 1960, they are still considered by the government to be too high. Two-fifths of the population is younger than 15 years of age. The government has been trying to decrease the growth rate with family-planning programs since 1968. Emigration is encouraged, and New York City has been a major destination. Immigration, particularly of Haitian labourers, has been restricted since 1965.

More than half of the population was living in urban areas in 1980 after extensive rural-to-urban migration during the 1970s, mostly because of the government's intensive development of Santo Domingo.

The economy. The Dominican Republic has a mixed economy in which both the public and private sectors participate. It is heavily dependent on the production and export of sugar, and unemployment and underemployment affect up to half of the work force. The gross national product (GNP) is slowly increasing; the population, however, is increasing much more rapidly. The GNP per capita is among the lowest in the Caribbean.

Agriculture accounts for less than one-sixth of the gross domestic product (GDP) and employs up to one-half of the work force. Subsistence farming predominates and produces much of the nation's basic food. Rice and corn are the chief staples. Sugar accounts for as much as one-fourth of the Dominican Republic's exports. Significant quantities of tobacco, coffee, and cocoa are also grown for export.

The country's mineral industries are dominated by the production of gold, silver, and ferronickel, which amounts to approximately two-fifths of all exports. Petroleum is imported. Manufacturing industries account for about one-sixth of the GDP and employ about one-eighth of the work force. Light industries predominate and centre on the production of refined sugar, molasses, cigarettes, textiles, furniture, and fertilizers. Four-fifths of the nation's electricity is generated from imported fuels; the rest is generated from hydroelectric power. The government is actively promoting the development of tourism, which has become, after sugar, the most important source of foreign exchange.

The balance of trade has remained negative as a result of high prices for petroleum and the wide differential between domestic and international interest rates. Fuels, foodstuffs, and capital and consumer goods lead imports and come primarily from the United States and Venezuela; the United States is also the main export destination.

Government and social conditions. The Dominican Republic is a representative democracy whose constitution, promulgated in 1966, vests executive power in the president, who is directly elected to a four-year term. The president is commander in chief of the armed forces and has broad powers. He governs

with the assistance of an appointed cabinet. Legislative power is vested in the bicameral National Congress, comprising the Senate and the Chamber of Deputies, whose members are directly elected to four-year terms. The Senate has 30 members, one representing each province and the national district, while the Chamber of Deputies has 120 members chosen on the basis of population. The major political parties are the Dominican Revolutionary Party and the Reformist Party. The independent judiciary is headed by the Supreme Court.

A voluntary social-security system introduced in 1947 provides sickness, maternity, accidental-injury, old-age, disability, and survivor benefits. Health conditions are poor, particularly in rural areas. Health services are inadequate and are concentrated in urban areas. Poor sanitation contributes to the high incidence of infectious and parasitic diseases. The average life expectancy is about 65 years for males and about 69 years for females; the infant mortality rate is high.

Education is free in primary schools and, where available, compulsory between the ages of 7 and 14. Only a small percentage of students advance beyond the primary level. Higher education is available at several universities, including the Autonomous University of Santo Domingo, which was founded in 1538 and was one of the first universities in the New World.

The Dominican press has been relatively free from censorship since the Rafael Trujillo period. Newspapers are generally of a high quality. Radio and television broadcasting, both government and commercially operated, are widely received.

Cultural life Dominican culture is based on folk arts and traditions. Music, especially when accompanying dancing, is important at all social levels and in all regions. Typical forms are those with clear African antecedents. Literary clubs are popular, and local painters are gaining some international recognition.

History. Little is known of the pre-Columbian history of Hispaniola. When Columbus reached the island in 1492, it was inhabited by Caribs who had migrated from South America and preyed on the peaceable Arawak (or Taino) inhabitants. Columbus established a colony on the north (Atlantic) coast that was destroyed by the native Indians. On his second voyage another north-coast colony was founded, but it was soon abandoned and Santo Domingo was established on the Caribbean coast.

The Spanish colony of Hispaniola prospered until the greater riches of Mexico and Peru turned it by 1550 into a neglected and poverty-ridden outpost, which it remained for the next three centuries. In 1697 the western third of the island was formally ceded to France, and a prosperous sugar-producing colony based on black slavery grew up in the area that was later to become the independent nation of Haiti. All of Hispaniola island passed to France in 1795. The eastern two-thirds of the island were returned to Spain in 1809, and the colony declared its independence as the Dominican Republic in 1821. Within a matter of weeks, however, it was overrun by Haitian troops and occupied until 1844. Since then the country has been under the rule of a succession of dictatorial strongmen, except for short interludes of democratic government. Twice (1916–24 and 1965–66) the United States intervened during periods of revolution. In 1930 Rafael Trujillo came to power and established an absolute rule that lasted until his assassination in 1961. Joaquín Balaguer was first elected to the presidency in 1966 and served until 1978; his conservative government maintained close ties with the United States. In 1978 the country

experienced its first peaceful transfer of power to an opposition candidate, Antonio Guzmán Fernández. Guzmán moved cautiously to implement reforms, but a hurricane devastated the country in 1979, and the faltering economy produced inflation and strikes. Guzmán was succeeded by Salvador Jorge Blanco, who served as president in 1982–86. In an attempt to stabilize the economy, he initiated an unpopular austerity program. As a result, the aging (and by then blind) Balaguer was re-elected president in 1986. The opposition claimed fraud after Balaguer's reelections in 1990 and '94, and, in the face of massive demonstrations, he agreed to step down in 1996. The moderate Leonel Fernández, who won the 1996 election, oversaw unprecedented rates of economic growth. In 2000 Hipólito Mejía, a former agrarian engineer, was elected president. By the turn of the 21st century the Dominican Republic had developed a stronger base for democracy; however, its authoritarian and corporatist influences remained strong.

Dominion, town, Cape Breton county, north-eastern Nova Scotia, Canada, northwest of Glace Bay and northeast of Sydney, on the northeast coast of Cape Breton Island. The town originally was named Dominion No. 1 and was developed in the 1890s around a colliery (now defunct) of the Dominion Coal Company. The name of the coal town was changed to Dominion in 1906. The first of the coal mines in the area was closed in 1926; in 1955 a second mine was closed. A Miners' Memorial Museum is located in nearby Glace Bay. Inc. 1906. Pop. (1996) 2,452.

dominion, the status, prior to 1939, of each of the British Commonwealth countries of Canada, Australia, New Zealand, the Union of South Africa, Eire, and Newfoundland. Although there was no formal definition of dominion status, the Imperial Conference of 1926 described Great Britain and the dominions as "autonomous communities within the British Empire, equal in status, in no way subordinate one to another in any aspect of their domestic or external affairs, though united by a common allegiance to the Crown and freely associated as members of the British Commonwealth of Nations."

The main characteristics of dominion status were complete legislative authority as provided in the Statute of Westminster (1931) and, in the executive sphere, the right of dominion ministers to direct access to the sovereign. Internationally, it connoted the recognition of the dominions (except Newfoundland) as separate states, entitled to separate representation in the League of Nations and other international bodies, to appoint their own ambassadors, and to conclude their own treaties. At the same time, the dominions were not considered to stand in the same relation to the United Kingdom or among themselves as foreign countries. After 1947 the use of the expression was abandoned because it was thought in some quarters to imply a form of subordination, and the phrase "members of the Commonwealth" came into use.

The definition of 1926 was modified in 1949, when it was agreed that Commonwealth members were not obligated to recognize the British monarch as their sovereign. The monarch was accepted as the symbol of the free association of the independent member nations and as such was the head of the Commonwealth. India was the first country to enter into such an arrangement, and by the 21st century it had been joined by most of the other Commonwealth nations. *See also* Commonwealth.

Dominion Arboretum and Botanic Garden, Central Experimental Farm, Ottawa, part of the Plant Research Institute of Agriculture Canada (formerly Canada Department of Agriculture). Established in 1889, the arboretum is Canada's oldest. It occupies 40 hectares (99 acres) and includes about 10,000 kinds of plants. Its special collections of flowering crabs, lilacs, lilies, and hedge plants are used for research and displayed to the public. The Dominion Arboretum has three greenhouses and an herbarium containing some 695,000 preserved plant specimens.

Dominion Day: *see* Canada Day.

domino theory, also called **DOMINO EFFECT**, theory in U.S. foreign policy after World War II stating that the "fall" of a noncommunist state to communism would precipitate the fall of noncommunist governments in neighbouring states. The theory was first proposed by President Harry S. Truman to justify sending military aid to Greece and Turkey in the 1940s, but it became popular in the 1950s when President Dwight D. Eisenhower applied it to Southeast Asia, especially South Vietnam. The domino theory was one of the main arguments used in the Kennedy and Johnson administrations during the 1960s to justify increasing American military involvement in the Vietnam War.

domino whist, domino game for four players. Partners are drawn for as in the card game whist; the player drawing the highest domino leads. Each player takes seven dominoes, or bones. There are no tricks, trumps, or honours. The bones are played as in ordinary dominoes, a hand being finished when one of the players plays his last bone or when both ends are blocked. Pips are then counted, and the holders of the highest number have that number scored against them. The side that is first debited with 100 points loses the game.

dominoes, game played with small, rectangular blocks of wood or other material, each identified by a number of dots, or pips, on its face. The blocks usually are called bones, dominoes, or pieces and sometimes men, stones, or even cards.

The face of each piece is divided, by a line or ridge, into two squares, each of which is marked as would be a pair of dice, except that some squares are blank (indicated in the listing below by a zero). The usual set consists of 28 pieces, marked respectively: 6-6 ("double six"), 6-5, 6-4, 6-3, 6-2, 6-1, 6-0, 5-5, 5-4, 5-3, 5-2, 5-1, 5-0, 4-4, 4-3, 4-2, 4-1, 4-0, 3-3, 3-2, 3-1, 3-0, 2-2, 2-1, 2-0, 1-1, 1-0, 0-0. Some sets run up to 9-9 and others as high as 12-12.

Of two bones, the one bearing the greater number of dots is called the heavier, the other the lighter.

Dominoes in China date perhaps to the 12th century AD. They apparently were designed to represent all possible throws with two dice, for Chinese dominoes (which they called "dotted

cards") have no blank faces. Western dominoes probably were not derived from the Chinese. There is no record of them before the mid-18th century in Italy and France. Apparently they were introduced into England by French prisoners in the late 18th century. North American Eskimos also play a domino-like game, using as many as 148 pieces.

The principle in nearly all modern dominoes games is to match one end of a piece to another that is identically or reciprocally numbered. Most basic are the block and draw games for two to four players. The dominoes are shuffled face downward on the table. Players draw for the lead, which is won by the heaviest piece; each player then draws at random the number of pieces required for the game, usually seven. The bones left behind are called the boneyard (U.S.), or stock.

The leader plays first, generally playing his highest domino (since at the end the player with the fewest pips wins). By some rules, a player, after playing a double, may play another bone that matches it; *e.g.*, if a double six is played, another bone that has a six at one end may be played. The second player has to match the leader's pose, or play, by putting one of his bones in juxtaposition at one end. Doublets are placed à cheval (crosswise). If a player cannot match, he says "go" and his opponent plays, unless the draw game—the usual game—is being played, in which case the player who cannot match draws from the stock until he finds a bone that matches. If a player succeeds in posing all his bones, he calls "Domino!" and wins the hand, scoring as many points as there are pips on the bones still held by his opponent. If neither player can match, that player wins who has the fewest pips left in his hand, and he scores as many points as are left in the two hands combined (sometimes only the excess held by his opponent). Game may be set at 50 or 100 points.

There are a number of variations on the game, including domino whist; matador, the object of which is not to match the end number but to pose a number that, when added to an end, will make seven; and muggins, in which the object is to make the sum of the open-end pips on the layout a multiple of five.

dominus, plural **DOMINI**, in ancient Rome, "master," or "owner," particularly of slaves. The name became the official title for the emperor, beginning with Diocletian, who reigned from AD 284 to 305; and thus he and his successors are often referred to as the dominate (*dominatus*), as contrasted with the earlier principate (*principatus*) of Augustus and his successors. Some earlier emperors, such as Caligula (reigned AD 37–41), however, also had used the title. By Trajan's day it was the common form of address to the emperor.

In the Latin church, Dominus was used as the equivalent of the Hebrew Adonai and the Greek Kyrios, to refer to the Christian God. *Dominus* in medieval Latin referred to the "lord" of a territory or the overlord of a vassal. It was later used as a respectful form of address (Spanish *don*, Portuguese *dom*) and for the clergy (Italian *don*).

Domitian, Latin in full CAESAR DOMITIANUS AUGUSTUS, original name (until AD 81) TITUS FLAVIUS DOMITIANUS (b. Oct. 24, AD 51—d. Sept. 18, AD 96, Rome [Italy]), Roman emperor (AD 81–96), known chiefly for the reign of terror under which prominent members of the Senate lived during his last years.

Titus Flavius Domitianus was the second son of the future emperor Vespasian and Flavia Domitilla. During the civil war of AD 69 over the imperial crown, Domitian remained unharmed in Rome, but on December 18 he took refuge in the Capitol with his uncle Flavius Sabinus, escaping into hiding when the Capitol was stormed by supporters of Vitellius. On the entry of his father's supporters into Rome two days later he was saluted as Caesar, and

he became praetor next year. He attempted to turn the repressive military campaign of Petilius Cerialis in the Rhineland into a triumphal operation of his own; and for this and other excesses he is said to have required his father's pardon when the latter arrived at Rome in autumn AD 70. Domitian, however, was *princeps iuventutis* (an imperial prince) and was consul six times in Vespasian's lifetime; moreover, it was recognized that he would eventually succeed his brother Titus, who had no son and was 11 years older than Domitian. On Vespasian's death, in June 79, Domitian expected the same position as Titus had received under Vespasian, in particular, tribunician power and some form of *imperium*. These were not granted, and Domitian was evidently antagonistic to his brother and is alleged to have hastened his death, which occurred on Sept. 13, 81.

As emperor, Domitian was hated by the aristocracy. From the Trajanic writers Tacitus and Pliny the Younger (Suetonius is less partisan) it is hard to disentangle stock vituperation from genuine belief, but it seems certain that cruelty and ostentation were the chief grounds of his unpopularity, rather than any military or administrative incompetence. Indeed, his strict control over magistrates in Rome and the provinces won Suetonius' praise. In his secretariat he used both freedmen and knights, some of whom retained their posts after his death; and his *consilium* of close advisers, including senators, involved no departure from precedent. In legislation he was severe, and he incurred censure for attempting to curb vices from which he himself was not immune. It might be fairer to criticize him for undue paternalism. An edict ordaining destruction of half the provincial vineyards was typical: it was designed to encourage the growing of grain and to limit the importing of wine into Italy (where, meanwhile, no increased output was permitted), but Domitian was unable to carry the matter through.

His military and foreign policy was not uniformly successful. Both in Britain and in Germany advances were made by the Romans early in the reign, and the construction of the Rhine-Danube *limes* ("fortified line") owes more to Domitian than to any other emperor. But consolidation in Scotland was halted by serious wars on the Danube, where Domitian never achieved an entirely satisfactory settlement and, worse still, lost two legions and many other troops. This, though admitted even by Tacitus to be due to the slackness or rashness of his commanders, was naturally held against Domitian at Rome. It did not affect his popularity with the army, however, whose pay he had wisely raised by one-third in AD 84.

The real issue was his own constitutional and ceremonial position. He continued his father's policy of holding frequent consulates (he was consul *ordinarius* every year from 82 to 88); he became censor for life in 85, with conse-

quent control over senatorial membership and general behaviour; he wore triumphal dress in the Senate; and he presided, wearing Greek dress and a golden crown, over four yearly games on the Greek model, with his fellow judges wearing crowns bearing his own effigy among effigies of the gods. A grave source of offense was his insistence on being addressed as *dominus et deus* ("master and god").

The execution of his cousin Flavius Sabinus in 84 was an isolated event, but there are hints of more general trouble about 87. The crisis came with the revolt of Antonius Saturninus, governor of Upper Germany, on Jan. 1, 89. This was suppressed by the Lower German army, but a number of executions followed, and the law of *majestas* (treason) was later employed freely against senators. The years 93–96 were regarded as a period of terror hitherto unsurpassed.

Among Domitian's opponents was a group of doctrinaire senators, friends of Tacitus and Pliny and headed by the younger Helvidius Priscus, whose father of the same name had been executed by Vespasian. Their Stoic views were probably the cause of Domitian's expulsions of "philosophers" from Rome on two occasions.

Domitian's financial difficulties are a vexing question. Cruelty came earlier in his reign than rapacity, but eventually he regularly confiscated the property of his victims. His building program had been heavy: Rome received a new forum (later called Forum Nervae) and many other works. Then there were Domitian's new house on the Palatine and his vast villa on the Alban Mount. Meanwhile, the increased army pay was a recurrent cost. Probably only his confiscations averted bankruptcy in the last years. The conspiracy that caused his murder on Sept. 18, 96, was led by the two praetorian prefects, various palace officials, and the emperor's wife, Domitia Longina (daughter of Gnaeus Domitius Corbulo). Nerva, who took over the government at once, must clearly have been privy. The Senate was overjoyed at Domitian's death, but the army took it badly; and the next year they insisted on the punishment of those responsible.

(G.E.F.C.)

BIBLIOGRAPHY. Aspects of the emperor's reign and policies are analyzed in Brian W. Jones, *The Emperor Domitian* (1992).

Domna, Julia (Roman empress): see Julia Domna.

Domnus (pope): see Donus.

domovoy, in Slavic mythology, a household spirit appearing under various names and hav-

ing its origin in ancestor worship. A *domovoy* dwells in any number of places in each home: near the oven, under the doorstep, in the hearth. He never goes out beyond the boundaries of the household.

The *domovoy* is the guardian of the family and its wealth, but he is partial to conscientious and hard-working people. Any displeasure the *domovoy* feels with the actions of its family is displayed in troubles with the farm animals or in strange knocks and grating noises in the house. These last, however, could just be the *domovoy* amusing himself. He can, in any case, be easily placated.

The *domovoy* sees to it that the various traditional proprieties are observed. He can foresee the future, and his groans and weeping or singing and jumping are interpreted as portents of evil or good. No household would consider moving to a new location without formally inviting the *domovoy* to join it.

Domra (Indian caste): see *Dom*.

Domrémy-la-Pucelle, village, Vosges département, Lorraine région, northeastern France. It lies on the banks of the Meuse River, 38 miles (61 km) southeast of Bar-le-Duc. Domrémy was where St. Joan of Arc ("la Pucelle") was born about 1412. The village still has several medieval buildings, including St. Joan's birthplace, now a museum. Nearby is the church containing the font at which she was baptized. Pop. (1990) 190.

domus, plural **DOMUS**, private family residence of modest to palatial proportions, found primarily in ancient Rome and Pompeii. In contrast to the *insula* (*q.v.*), or tenement block, which housed numerous families, the *domus* was a single-family dwelling divided into two main parts, atrium and peristyle.

The more public functions and activities of the family took place in the atrium, generally a square or rectangular area subdivided around the perimeter into different spaces for conversation and relaxation; it was reached from the street through the *prothyrum*, an entrance passageway. Located between the atrium and peristyle was the *tablinum*, an open living room that could be curtained off from public view. A hallway, or *fauces*, was positioned to one side of the *tablinum*, to provide convenient access to the peristyle.

The concept of the atrium was derived from Etruscan domestic architecture, in which the atrium comprised the entire dwelling; the characteristic form of the peristyle was taken

Peristyle in the House of the Vettii, Pompeii, Italy, 1st century AD

Foto Vasari

from the Greek house of around the 2nd century BC.

The peristyle of the domus, typified by that of the House of the Vettii at Pompeii, contained the private living quarters of the family; clustered around its colonnaded court were the *oecus* (reception room), *cubicula* (bedrooms), *alae* (recesses for private talk), and *triclinia* (dining rooms), with different exposures that could be regulated according to the seasons. In the House of Pansa in Pompeii, the dining rooms were furnished with three couches, each seating three people, nine being the accepted number of guests for a Roman feast. Also in that domus a series of small upper-story rooms encircled the atrium and peristyle.

The Palatine Hill in Rome was celebrated for its palatial houses, among them the Domus Augustana; the Domus Augusti (Villa of Livia) of about 55 BC; and the Domus Tiberiana (destroyed AD 80), which became the residence of the emperors. Nero's opulent palace, the Domus Aurea (AD 64–68), was also located on the Palatine.

Domus Aurea: see Golden House of Nero.

Dôn, in Celtic mythology, leader of one of two warring families of gods; according to one interpretation, the Children of Dôn were the powers of light, constantly in conflict with the Children of Llyr, the powers of darkness. In another view, the conflict was a struggle between indigenous gods and those of an invading people. Although Dôn and other Welsh deities had Irish analogues (the Irish goddess Danu, e.g.), the stories surrounding them differed, and the Welsh mythology has only partially survived.

Dôn's children included Gwydion, a master of magic, poetry, and music and a warrior who clashed frequently with various gods, and Aranrhod, a sky goddess and symbol of fertility, who bore Gwydion twin sons: Dylan, a sea god, and Lleu Llaw Gyffes (Lleu of the Dexterous Hand), whom many scholars consider analogous to the Irish god Lug.

Don, River, river in England that rises at about 1,500 ft (460 m) in the Pennine range. It flows in a deeply entrenched course across the South Yorkshire coalfield past the city of Sheffield, where its basin forms the heart of the steelmaking district. From there the river flows northeastward past Doncaster, an ancient Roman crossing point and modern coal-mining centre, and the valley widens. The Don joins the Ouse at Goole after a course of about 70 mi (110 km).

Don, River, river in north central Scotland, rising on the slopes of Meikle Geal Chàrn and flowing generally eastward parallel to the River Dee further south, and emptying into the North Sea at Aberdeen after a course of 82 mi (132 km). In its upper course it receives a number of short mountain streams, but in its lower stretches it flows more gently through a lowland area of agriculture and livestock-raising. The main river town above Aberdeen is Inverurie.

Don Juan, fictitious character who is a symbol of libertinism. Originating in popular legend, he was first given literary personality in the tragic drama *El burlador de Sevilla* (1630; "The Seducer of Seville"), attributed to the Spanish dramatist Tirso de Molina. Through Tirso's tragedy, Don Juan became a universal character, as familiar as Don Quixote, Hamlet, and Faust. Subsequently, he became the hero-villain of plays, novels, and poems; his legend was assured enduring popularity through Mozart's opera *Don Giovanni* (1787). The legend of Don Juan tells how, at the height of his licentious career, he seduced a girl of noble

"Come with Me to My Castle," illustration to Act I of Mozart's *Don Giovanni*, after a drawing by J.H. Ramberg

The Bettmann Archive

family and killed her father, who had tried to avenge her. Later, seeing a commemorative effigy on the father's tomb, he flippantly invited it to dine with him, and the stone ghost duly arrived for dinner as a harbinger of Don Juan's death. In the original Spanish tragedy, Don Juan's attractive qualities—his vitality, his arrogant courage, and his sense of humour—heighten the dramatic value of the catastrophe. The power of the drama derives from its rapid pace, the impression it gives of cumulative tension as Don Juan's enemies gradually hound him to destruction, and the awareness that the Don is goaded to defy even the ghostly forces of the unknown. In the end he refuses to repent and falls to eternal damnation.

In the 17th century the Don Juan story became known to strolling Italian players, some of whom travelled to France with this theme in their repertoire of pantomime, and by the 19th century many foreign versions of the Don Juan legend existed. Along with Mozart's opera, other famous non-Spanish versions are Molière's *Le Festin de pierre* (1665; "The Stone Feast"), based on earlier French arrangements; Prosper Mérimée's short story "Les Ames du Purgatoire"; and the drama *Don Juan de Marana* (1836) by the elder Dumas. Early English versions—T. Shadwell's *The Libertine* (1676), for example—are considered uninspired, but later the character reappears with a new force in Byron's long satiric poem *Don Juan* (1819–24) and in George Bernard Shaw's drama *Man and Superman* (1903). Later Spanish versions retain Don Juan's likable qualities and avoid the calculated cynicism of certain foreign versions.

The highly popular *Don Juan Tenorio* (1844) of José Zorrilla y Moral, still traditionally performed in Spain on the eve of All Soul's Day (Halloween), borrowed lavishly from French sources. Zorrilla's play is said to sentimentalize the legend by furnishing a pious heroine and a serious love interest and by procuring Don Juan's repentance and salvation.

Don Pacifico Affair (1850), a quarrel between Great Britain and Greece, in which British acts antagonized France and Russia and caused controversy at home.

David Pacifico (known as Don Pacifico) was a Portuguese Jew who, having been born in Gibraltar in 1784, was a British subject.

After serving as Portuguese consul in Morocco (1835–37) and then as consul-general in Greece, he settled in Athens as a merchant. In 1847 his house was burned down in an anti-Semitic riot, the police standing quietly by. Pacifico demanded compensation from the Greek government and was supported by Britain's foreign secretary, Lord Palmerston. Palmerston sent a naval squadron to blockade the Greek coast (January 1850) and force the Greeks to meet Pacifico's demands. This brought protests from the French and the Russians, with whom Britain shared a protectorate of Greece. Nevertheless, the Greeks acceded to the payment of £4,000, though, because of the loss of some papers, a commission awarded Pacifico only £150. He moved to London, where he died on April 12, 1854.

The incident had its greatest effect in British internal politics. Palmerston's policy was censured by the House of Lords (June 18, 1850), but he won the support of the Commons on June 29. During his speech before the vote, he made his famous comparison between the British and Roman empires, saying that, just as a Roman could claim his rights anywhere in the world with the words "Civis Romanus sum" ("I am a Roman citizen"), "so also a British subject, in whatever land he may be, shall feel confident that the watchful eye and the strong arm of England will protect him against injustice and wrong."

Don Quixote, Spanish in full *EL INGENIOSO HIDALGO DON QUIJOTE DE LA MANCHA*, novel published in two parts (Part I, 1605; Part II, 1615) by Miguel de Cervantes, one of the most widely read classics of Western literature. Originally conceived as a comic satire against the chivalric romances then in literary vogue, it describes realistically what befalls an elderly knight who, his head bemused by reading romances, sets out on his old horse Rosinante, with his pragmatic squire Sancho Panza, to seek adventure. Widely and immediately translated (first English translation in 1612), the novel was a great and continuing success. Modern English translations include those by J.M. Cohen (1950) and Samuel Putnam (2 vol., 1959).

Don River, historic river of Russia. The Don River rises in the small reservoir of Shat near the city of Novomoskovsk, south of Moscow in the central Russian uplands and flows for 1,162 mi (1,870 km) in a generally southerly direction until it enters the Gulf of Taganrog in the Sea of Azov.

The following article summarizes information about the Don River. For full treatment, see *MACROPAEDIA: Europe*.

The major tributaries are the Krasivaya Mecha, Sosna, Chir, and Donets (right bank) and the Voronezh, Khopyor, and Manych (left bank). In its upper course the Don flows along the eastern edge of the central Russian heights through a narrow valley; in its middle course the valley widens to about 4 mi, and the river flows into the Tsimlyansk Reservoir, which dominates the Don's lower course. The Tsimlyansk Reservoir (188 mi long, 24 mi wide) has raised the level of the river by 85 ft, regularized the annual flow, and made the lower course a major transportation artery. The climate of the basin is moderately continental with average January temperatures of 12° to 18° F (–11° to –8° C) and July temperatures of 66° to 72° F (19° to 22° C); annual precipitation decreases from 23 in. (584 mm) in the north to 14 to 15 in. in the south. The Don is primarily fed by snow; it annually carries about 6,800,000 tons (6,200,000 metric tons) of dissolved mineral substances to the Sea of Azov. Most of the basin (163,000 sq mi [422,000 sq km]) is rich farm and timber land; an extensive network of canals provides irrigation in the lower course. The river carries cargoes of lumber, grain, building materials, and other bulk freight. Its delta has valuable

fish (pike, perch, carp, sturgeon) resources. The river is navigable (in the spring) as far as 990 mi from the Sea of Azov; straightening and dredging operations are necessary to maintain navigation in the upper reaches. The largest ports are Kalach-na-Donu, Tsimlyansk, and Rostov-na-Donu.

Donalbane (king of Scotland); see Donald Bane.

Donald I (d. 862), king of Alba, the united kingdom of the Picts and Scots (858–862), brother and successor of Kenneth I MacAlpin. Donald established an ancient corpus of laws and rights (known as the laws of Aed, or Aedh) that apparently included the custom of tanistry. According to this custom, the successor of a king was elected during his lifetime from the eldest and worthiest of his kin, often a collateral (brother or cousin) in preference to a descendant (son). The next king, Donald's brother Constantine I, succeeded in accordance with this custom.

Donald II (d. 900), king of the Scots (from 889), son of Constantine I and successor to Eochaid and Giric (reigned 878–889). His reign coincided with renewed invasions by the Danes, who came less to plunder and more to occupy the lands bordering Scotland and the Anglo-Saxon kingdoms. He was also embroiled in efforts to reduce the highland robber tribes. By one account he was slain at Dunnottar, meeting a Danish invasion; by another he died of infirmity brought on by his campaigns against the highlanders. He was succeeded by his cousin Constantine II.

Donald Bane, also spelled DONALDBANE, or DONALBANE, Bane also spelled BAN or BAIN (b. c. 1033—d. after 1097), king of Scotland from November 1093 to May 1094 and from November 1094 to October 1097, son of Duncan I.

Upon the death of his brother Malcolm III Canmore (1093) there was a fierce contest for the crown. Donald Bane besieged Edinburgh Castle, took it, and, with the support of the Celtic Scots and the custom of tanistry (*q.v.*: the Celtic system of electing kings or chiefs), he was king nominally for at least six months. He was expelled by Duncan II, son of Malcolm, assisted by English and Normans and some Saxons. Duncan's reign was equally short, for Donald Bane had his nephew slain and again reigned for three years.

These years saw the last attempt of the Celts to maintain a king of their race and a kingdom governed according to their customs. Edgar the Aetheling (*q.v.*), who had newly befriended the Norman king of England, led an army into Scotland, dispossessed Donald Bane, and advanced his nephew Edgar, son of Malcolm III, as sole king of the Scots.

Donaldson, Walter (b. Feb. 15, 1893, Brooklyn, N.Y., U.S.—d. July 15, 1947, Santa Monica, Calif., U.S.), U.S. lyricist, arranger, pianist, and prolific composer of popular songs for stage productions and films.

Donaldson began his career as a pianist for a music publisher. After 19 months spent entertaining troops at Camp Upton, New York, during World War I, he joined the new publishing firm of composer Irving Berlin. In 1928 he established his own music publishing company, Donaldson, Douglas and Gumble.

Donaldson's first success on Broadway was with "My Mammy," introduced by Al Jolson in the show *Sinbad* (1918), and he continued writing for Broadway revues for more than 25 years. The period 1925–28 was his most productive and lucrative. His most popular compositions include "My Buddy," "My Blue Heaven," "Yes Sir, That's My Baby," "Love Me or Leave Me," "Carolina in the Morning," "You're Driving Me Crazy," and his score for *Whoopie* (1928). He collaborated with many of the best known lyricists of his day,

among them Gus Kahn, Sam M. Lewis, Joe Young, Edgar Leslie, Harold Adamson, and Johnny Mercer. Donaldson first contributed songs, incidental music, and arrangements to films in 1934 and worked on *The Great Ziegfeld* (1936), *Sinner Take All* (1936), *After the Thin Man* (1936), and *Saratoga* (1937), among others. His work was characteristically lighthearted or sentimental, and his lyrics frequently made use of the vernacular, as in his 1943 song "What's Buzzin', Cousin?"

donatário, the recipient of a *capitania* (captaincy), both a territorial division and a royal land grant in Portuguese colonies, especially Brazil. The Portuguese had used the captaincy system with success in the Madeira Islands and the Azores, and in 1533 King John III decided to employ it to consolidate Portuguese power in Brazil.

An elaborate set of regulations governed the system. In exchange for the land grant and certain tax immunities, the *donatário* was charged with the specific responsibilities of gathering settlers, caring for their spiritual welfare, and protecting them from attack, and with promoting agriculture and commerce. Most of the land of the captaincy, aside from the private grant of the *donatário*, was to be given to settlers. The *donatário* was to bear all the expenses of the captaincy himself. Each captaincy consisted of a portion of land from 25 to 60 or more leagues (75 to 180 or more miles) wide along the Brazilian coast and extending inland to the line (between 48° and 49° west of Greenwich) established by the Treaty of Tordesillas (1494), which divided Portuguese and Spanish colonial possessions.

The nearly monarchical powers theoretically possessed by the *donatário* were limited in practice by the difficulties in gaining actual control of his domain, of acquiring a sufficient labour force (enslavement of Indians was not easy, and black slaves were not imported in large numbers in the 16th century), of defending his captaincy from French incursions with almost no aid from the Portuguese government, and of mastering unruly colonists, most of whom were criminals or dissenters exiled from Portugal.

By 1549, of the 12 captaincies that had been set up in Brazil, only two showed a profit: Pernambuco, granted to Duarte Coelho Pereira, and São Vicente, granted to Martim Afonso de Sousa. To save the colony of Brazil, John III in 1549 dispatched Tomé de Sousa as captain general, along with a small band of Jesuits headed by Manuel da Nóbrega. Through their efforts and those of the succeeding captain general, Mem de Sá (1557–72), workable policies for the colony were formed and implemented, and vigorous attempts were made to gather the Indians into settlements. There were eight captaincies by 1580, and Brazil had become an economically viable, though not a wealthy, colony. Its capital was at Bahia. In time the *donatários* were supplanted by officials called captains or governors. By 1754 all the captaincies had been abolished.

Donatello (b. c. 1386, Florence—d. Dec. 13, 1466, Florence), master of sculpture in both marble and bronze, one of the greatest of all Italian Renaissance artists.

A good deal is known about Donatello's life and career, but little is known about his character and personality, and what is known is not wholly reliable. He never married and he seems to have been a man of simple tastes. Patrons often found him hard to deal with in a day when artists' working conditions were regulated by guild rules. Donatello seemingly demanded a measure of artistic freedom. Although he knew a number of Humanists well, the artist was not a cultured intellectual. His Humanist friends attest that he was a connoisseur of ancient art. The inscriptions and signatures on his works are among the earliest examples of the revival of classical Roman let-

tering. He had a more detailed and wide-ranging knowledge of ancient sculpture than any other artist of his day. His work was inspired

Equestrian statue of Gattamelata, bronze sculpture by Donatello, 1447–53; in the Piazza del Santo, Padua, Italy

Anderson—Alinari from Art Resource/EB Inc

by ancient visual examples, which he often daringly transformed. Though he was traditionally viewed as essentially a realist, later research indicates he was much more.

Early career. Donatello (diminutive of Donato) was the son of Niccolò di Betto Bardi, a Florentine wool carder. It is not known how he began his career, but it seems likely that he learned stone carving from one of the sculptors working for the cathedral of Florence about 1400. Some time between 1404 and 1407 he became a member of the workshop of Lorenzo Ghiberti, a sculptor in bronze who in 1402 had won the competition for the doors of the Florentine baptistery. Donatello's earliest work of which there is certain knowledge, a marble statue of David, shows an artistic debt to Ghiberti, who was then the leading Florentine exponent of International Gothic, a style of graceful, softly curved lines strongly influenced by northern European art. The "David," originally intended for the cathedral, was moved in 1416 to the Palazzo Vecchio, the city hall, where it long stood as a civic-patriotic symbol, although from the 16th century on it was eclipsed by the gigantic "David" of Michelangelo, which served the same purpose. Other of Donatello's early works, still partly Gothic in style, are the impressive seated marble figure of St. John the Evangelist for the cathedral facade and a wooden crucifix in the church of Sta. Croce. The latter, according to an unproved anecdote, was made in friendly competition with Brunelleschi, a sculptor and an architect.

The full power of Donatello first appeared in two marble statues, "St. Mark" and "St. George" (both completed c. 1415), for niches on the exterior of Or San Michele, the church of Florentine guilds ("St. George" has been replaced by a copy; the original is now in the Bargello). Here, for the first time since classical antiquity and in striking contrast to medieval art, the human body is rendered as a self-activating, functional organism, and the human personality is shown with a confidence in its own worth. The same qualities came increasingly to the fore in a series of five prophet statues that Donatello did beginning in 1416 for the niches of the campanile, the bell tower of the cathedral (all these figures, together with others by lesser masters, were later removed to the Museo dell'Opera del Duomo). The statues were of a beardless and a bearded prophet, as well as a group of Abraham and Isaac (1416–21) for the eastern niches; the so-called "Zuccone" ("pumpkin," because of its bald head); and the so-called "Jeremiah"

(actually Habakkuk) for the western niches. The "Zuccone" is deservedly famous as the finest of the campanile statues and one of the artist's masterpieces. In both the "Zuccone" and the "Jeremiah" (1427-35), their whole appearance, especially highly individual features inspired by ancient Roman portrait busts, suggests classical orators of singular expressive force. The statues are so different from the traditional images of Old Testament prophets that by the end of the 15th century they could be mistaken for portrait statues.

A pictorial tendency in sculpture had begun with Ghiberti's narrative relief panels for the north door of the baptistery, in which he extended the apparent depth of the scene by placing boldly rounded foreground figures against more delicately modeled settings of landscape and architecture. Donatello invented his own bold new mode of relief in his marble panel "St. George Killing the Dragon" (1416-17, base of the St. George niche at Or San Michele). Known as *schacciato* ("flattened out"), the technique involved extremely shallow carving throughout, which created a far more striking effect of atmospheric space than before. The sculptor no longer modeled his shapes in the usual way but rather seemed to "paint" them with his chisel. A blind man could "read" a Ghiberti relief with his fingertips; a *schacciato* panel depends on visual rather than tactile perceptions and thus must be seen.

Donatello continued to explore the possibilities of the new technique in his marble reliefs of the 1420s and early 1430s. The most highly developed of these are "The Ascension, with Christ Giving the Keys to St. Peter," which is so delicately carved that its full beauty can be seen only in a strongly raking light; and the "Feast of Herod" (1433-35), with its perspective background. The large stucco roundels with scenes from the life of St. John the Evangelist (about 1434-37), below the dome of the old sacristy of San Lorenzo, Florence, show the same technique but with colour added for better legibility at a distance.

Meanwhile, Donatello had also become a major sculptor in bronze. His earliest such work was the more than life-size statue of St. Louis of Toulouse (c. 1423) for a niche at Or San Michele (replaced half a century later by Verrocchio's bronze group of Christ and the doubting Thomas). Toward 1460 the "St. Louis" was transferred to Santa Croce and is now in the museum attached to the church. Early scholars had an unfavourable opinion of "St. Louis," but later opinion held it to be an achievement of the first rank, both technically and artistically. The garments completely hide the body of the figure, but Donatello successfully conveyed the impression of harmonious organic structure beneath the drapery. Donatello had been commissioned to do not only the statue but the niche and its framework. The niche is the earliest to display Filippo Brunelleschi's new Renaissance architectural style without residual Gothic forms. Donatello could hardly have designed it alone; Michelozzo, a sculptor and architect with whom he entered into a limited partnership a year or two later, may have assisted him. In the partnership, Donatello contributed only the sculptural centre for the fine bronze effigy on the tomb of the schismatic pope John XXIII in the baptistery; the relief of the "Assumption of the Virgin" on the Brancacci tomb in Sant'Angelo a Nilo, Naples; and the balustrade reliefs of dancing angels on the outdoor pulpit of Prato Cathedral (1433-38). Michelozzo was responsible for the architectural framework and the decorative sculpture. The architecture of these partnership projects resembles that of Brunelleschi and differs sharply from that of comparable works done by Donatello alone in

the 1430s. All of his work done alone shows an unorthodox ornamental vocabulary drawn from both classical and medieval sources and an un-Brunelleschian tendency to blur the distinction between the architectural and the sculptural elements. Both the Annunciation tabernacle in Santa Croce and the "Cantoria" (the singer's pulpit) in the Duomo (now in the Museo dell'Opera del Duomo) show a vastly increased repertory of forms derived from ancient art, the harvest of Donatello's long stay in Rome (1430-33). His departure from the standards of Brunelleschi produced an estrangement between the two old friends that was never repaired. Brunelleschi even composed epigrams against Donatello.

During his partnership with Michelozzo, Donatello carried out independent commissions of pure sculpture, including several works of bronze for the baptismal font of San Giovanni in Siena. The earliest and most important of these was the "Feast of Herod" (1423-27), an intensely dramatic relief with an architectural background that first displayed Donatello's command of scientific linear perspective, which Brunelleschi had invented only a few years earlier. To the Siena font Donatello also contributed two statuettes of Virtues, austere beautiful figures whose style points toward the Virgin and angel of the Santa Croce Annunciation, and three nude putti, or child angels (one of which was stolen and is now in the Berlin museum). These putti, evidently influenced by Etruscan bronze figurines, prepared the way for the bronze David, the first large-scale, free-standing nude statue of the Renaissance. Well-proportioned and superbly poised, it was conceived independently of any architectural setting. Its harmonious calm makes it the most classical of Donatello's works. The statue was undoubtedly done for a private patron, but his identity is in doubt. Its recorded history begins with the wedding of Lorenzo the Magnificent in 1469, when it occupied the centre of the courtyard of the Medici palace in Florence. After the expulsion of the Medici in 1496, the statue was placed in the courtyard of the Palazzo Vecchio.

Whether the "David" was commissioned by the Medici or not, Donatello worked for them (1433-43), producing sculptural decoration for the old sacristy in San Lorenzo, the Medici church. Works there included 10 large reliefs in coloured stucco and two sets of small bronze doors, which showed paired saints and apostles disputing with each other in vivid and even violent fashion.

Paduan period. In 1443, when Donatello was about to start work on two much more ambitious pairs of bronze doors for the sacristies of the cathedral, he was lured to Padua by a commission for a bronze equestrian statue of a famous Venetian condottiere, Erasmo da Narmi, popularly called Gattamelata ("The Honeyed Cat"), who had died shortly before. Such a project was unprecedented—indeed, scandalous—for since the days of the Roman Empire bronze equestrian monuments had been the sole prerogative of rulers. The execution of the monument was plagued by delays. Donatello did most of the work between 1447 and 1450, yet the statue was not placed on its pedestal until 1453. It portrays Gattamelata in pseudo-classical armour calmly astride his mount, the baton of command in his raised right hand. The head is an idealized portrait with intellectual power and Roman nobility. This statue was the ancestor of all the equestrian monuments erected since. Its fame, enhanced by the controversy, spread far and wide. Even before it was on public view, the king of Naples wanted Donatello to do the same kind of equestrian statue for him.

In the early 1450s, Donatello undertook some important works for the Paduan Church of San Antonio: a splendidly expressive bronze crucifix and a new high altar, the most ambitious

of its kind, unequalled in 15th-century Europe. Its richly decorated architectural framework of marble and limestone contains seven life-size bronze statues, 21 bronze reliefs of various sizes, and a large limestone relief, "Entombment of Christ." The housing was destroyed a century later, and the present arrangement, dating from 1895, is wrong both aesthetically and historically. The majestic Madonna, with an austere frontal pose seemingly a conscious reference to an earlier venerated image, and the delicate, sensitive St. Francis are particularly noteworthy. The finest of the reliefs are the four miracles of St. Anthony, wonderfully rhythmic compositions of great narrative power. Donatello's mastery in handling large numbers of figures (one relief has more than 100) anticipates the compositional principles of the High Renaissance.

Donatello was apparently inactive during the last three years at Padua, the work for the San Antonio altar unpaid for and the Gattamelata monument not placed until 1453. He had dismissed the large force of sculptors and stone masons used on these projects. Offers of other commissions reached him from Mantua, Modena, Ferrara, and even perhaps from Naples, but nothing came of them. Clearly, Donatello was passing through a crisis that prevented him from working. He was later quoted as saying that he almost died "among those frogs in Padua." In 1456 the Florentine physician Giovanni Cellini noted in his account book that he had successfully treated the master for a protracted illness. Donatello completed only two works between 1450 and 1455: the wooden statue "St. John the Baptist" in Santa Maria Gloriosa dei Frari, Venice, shortly before his return to Florence; and an even more extraordinary figure of Mary Magdalen in the Florentine baptistery. Both works show new insight into psychological reality; Donatello's formerly powerful bodies have become withered and spidery, overwhelmed, as it were, by emotional tensions within. When the "Magdalen" was damaged in the 1966 flood at Florence, restoration work revealed the original painted surface, including realistic flesh tones and golden highlights throughout the saint's hair.

Late Florentine period. During Donatello's absence, a new generation of sculptors who excelled in the sensuous treatment of marble surfaces had arisen in Florence. Thus Donatello's wooden figures must have been a shock. With the change in Florentine taste, all of Donatello's important commissions came from outside Florence. They included the dramatic bronze group "Judith and Holofernes" (later acquired by the Medici and now standing before the Palazzo Vecchio) and a bronze statue of St. John the Baptist for Siena Cathedral, for which he also undertook in the late 1450s a pair of bronze doors. This ambitious project, which might have rivaled Ghiberti's doors for the Florentine baptistery, was abandoned about 1460 for unknown reasons (most likely technical or financial). Only two reliefs for them were executed; one of them is probably the "Lamentation" panel now in the Victoria and Albert Museum, London.

The last years of Donatello's life were spent designing twin bronze pulpits for San Lorenzo, and, thus, again in the service of his old patrons the Medici, he died. Covered with reliefs showing the passion of Christ, the pulpits are works of tremendous spiritual depth and complexity, even though some parts were left unfinished and had to be completed by lesser artists.

(H.W.J./Ed.)
BIBLIOGRAPHY. H.W. Janson, *The Sculpture of Donatello*, 2 vol., (1957), available also in a 1-vol. ed. with fewer illustrations (1963, reissued 1979), is an exhaustive critical catalog, with full digest of documents, sources, and scholarly literature up to 1955. Bonnie A. Bennett and David G. Wilkins, *Donatello* (1984), synthesizes current scholarship. John Pope-Hennessy, *Italian Renais-*

sance *Sculpture*, 3rd ed. (1985); and Charles Seymour, *Sculpture in Italy: 1400 to 1500* (1966), both contain stimulating discussions of Donatello in the context of the art of his time.

Donati, Corso (d. Oct. 6, 1308, Florence [Italy]), Florentine nobleman and soldier who formed and led the political faction known as the Blacks (Neri). He was master of Florence from 1301 to 1308.

Of a prominent Guelph (pro-papal) family, Donati acquired much influence in the Florentine government, especially after his victory over the citizens of Arezzo at Campaldino (1289). He then formed the party of the Blacks, supported by the aristocracy, against the party of the Whites (Bianchi), which wished to exclude the nobles from office. In 1300, however, the *signoria*, the ruling body of Florence, seeking to bring peace to the city, exiled both Donati and Vieri dei Cerchi, chief of the Whites. Donati fled to Rome under the protection of Pope Boniface VIII. Securing the aid of Charles of Valois (1270–1325), he returned in triumph to Florence in 1301 and controlled it until 1308. Although he twice banished the Whites (1304 and 1308), his enemies were not yet routed. When he plotted for a second time to become *signore* (lord) of Florence, a popular uprising resulted, and he died attempting escape.

Donati, Giovanni Battista (b. Dec. 16, 1826, Pisa [Italy]—d. Sept. 20, 1873, Florence), Italian astronomer who, on Aug. 5, 1864, was first to observe the spectrum of a comet (Comet 1864 II). This observation indicated correctly that comet tails contain luminous gas and do not shine merely by reflected sunlight.

Between 1854 and 1864 Donati discovered six comets, one of which, first seen on June 2, 1858, bears his name. These discoveries led to his appointment as professor of astronomy and director of the observatory at Florence in 1864. He also contributed to early classification systems for stellar spectra. Donati was supervising the building of a new observatory at Arcetri, near Florence, when he died.

Donatia, the only genus of the family Donatiaceae, of the bellflower order (Campanulales), containing two species of small cushion plants, native to Tasmania, New Zealand, and sub-Antarctic South America. The little plants form dense spirals of narrow, thick, leathery leaves. Donatia flowers, borne singly at the ends of short stems, have 5 to 7 sepals and 5 to 10 petals. The top-shaped fruits contain a few fleshy seeds.

Donation of Pepin: see Pepin, Donation of.

Donatist, a member of a Christian group in North Africa that broke with the Roman Catholics in 312 over the election of Caecilian as bishop of Carthage; the name derived from their leader, Donatus (d. c. 355). Historically, the Donatists belong to the tradition of early Christianity that produced the Montanist and Novatianist movements in Asia Minor and the Melitians in Egypt. They opposed state interference in church affairs, and, through the peasant warriors called Circumcellions, they had a program of social revolution combined with eschatological hopes. Martyrdom following a life of penance was the goal of the religiously minded Donatist. Despite almost continuous pressure from successive Roman, Vandal, and Byzantine rulers of North Africa, the Donatist church survived until the extinction of Christianity in North Africa in the early European Middle Ages.

The ultimate causes of the schism were both doctrinal and social. Throughout the 3rd century the prevailing tradition in the African church had regarded the church as a body of the elect. This view, which was espoused by Cyprian and developed in response to earlier

controversy, had as its corollary the belief that the validity of sacerdotal acts depended on the presence of the Holy Spirit in the minister and that a minister who was not in a state of grace could not administer a valid sacrament. At the same time, riches and sin had tended to become identified; mammon and the Roman world were equally to be shunned.

In 311 Caecilian was elected bishop, but he was opposed by many because he allowed himself to be consecrated by a *traditor* bishop (one who had surrendered copies of Scripture to the authorities during Emperor Diocletian's persecution of Christians, beginning in 303). The primate of Numidia, Secundus of Tigisi, who had acquired in the previous 40 years the right of consecrating the bishop of Carthage, arrived in Carthage with 70 bishops and in solemn council declared Caecilian's election invalid. The council then appointed a reader (lector), Majorinus, to replace Caecilian.

The new emperor, Constantine the Great, ordered arbitration of the controversy. A mixed commission of Italian and Gallic bishops under the presidency of Miltiades, bishop of Rome, found Caecilian innocent of all charges on Oct. 2, 313. Meantime, Majorinus had been replaced by Donatus, who appealed against Miltiades' judgment. Constantine summoned a council of bishops from the western provinces of the empire at Arles on Aug. 1, 314, and again Caecilian was upheld and his position strengthened by a canon that ordination was not invalid if it had been performed by a *traditor*. Despite further appeals by Donatus and his supporters, Constantine gave a final decision in favour of Caecilian in November 316.

The schism did not die out. Persecution from 317 to 321 failed, and in May 321 Constantine grudgingly granted toleration to the Donatists. The movement gained strength for several years, but in August 347 Emperor Constans I exiled Donatus and other leaders to Gaul, where Donatus died about 355.

When Julian the Apostate became emperor in 361, the exiled Donatists returned to Africa and were the majority Christian party for the next 30 years. Their opponents, however, now led by St. Augustine of Hippo, gained strength, and in 411 a conference presided over by Augustine's friend the imperial tribune Marcellinus was held in Carthage. This council decided against the Donatists and for the Catholics. In 412 and 414 severe laws denied the Donatists civil and ecclesiastical rights; however, the Donatists expected hostility from the world as part of the natural order of things, and they survived into the 7th century.

Donatus, Aelius (fl. mid-4th century AD), famous grammarian and teacher of rhetoric at Rome, one of whose pupils became St. Jerome.

Donatus wrote a large and a small school grammar, *Ars maior* and *Ars minor*. The latter, written for young students, gives, by question and answer, elementary instruction in the eight parts of speech. It remained in use throughout the European Middle Ages, and its author's name in the forms *donat* and *donet* came to mean "grammar" or any kind of "lesson." The larger work, in three parts, deals with the elements of grammar, the eight parts of speech, and errors and beauties of language. Donatus has little claim to originality, but no grammar is cited so often, and many commentaries were written on it.

Donatus also wrote commentaries on Terence and Virgil. The former in its original form is lost, and the version that has survived lacks the notes on the *Hautontimorumenos* ("Self-Tormentor"). Donatus' valuable commentary was based on excellent sources and on careful study of Terence. It contains interesting notes on scenic representation and comparisons with Greek originals. Of the

commentary on Virgil there survive only the preface and dedication, a life of Virgil, the introduction to the *Bucolics*, and quotations.

Aelius Donatus is to be distinguished from Tiberius Claudius Donatus, probably late 4th century AD, author of the *Interpretationes Vergilianae*, a commentary on the *Aeneid*.

Donauwörth, city and port, Bavaria Land (state), southern Germany, at the confluence of the Danube and Wörnitz rivers, some 25 miles (40 km) north-northwest of Augsburg.

There is evidence of settlement of the site of Donauwörth from the 6th century. The city itself grew up around the Mangoldstein, a 9th-century fortress. In the mid-13th century it became the seat of dukes of Upper Bavaria, and it was created a free imperial city (known then mostly as Schwäbisch Wörth) in 1301. The city endorsed the Reformation in 1555 and was the scene of riots in 1607, when supporters of the Counter-Reformation attempted to reconvert the population to Roman Catholicism. This event helped touch off the Thirty Years' War. Donauwörth was occupied by Bavaria in 1608 and was restored to its status as a free imperial city in 1714.

Despite heavy bombing in World War II, Donauwörth retains a medieval town hall (1309), and several 15th-century churches and two gates of the medieval fortifications still stand. Industry is dominated by steel and motor-vehicle manufacturing. Donauwörth's scenic alpine location and its picturesque medieval buildings promote a thriving tourist industry. Pop. (latest est.) 18,000.

Donbass, also spelled DONBAS (Ukraine and Russia): see Donets Coal Basin.

Doncaster, town and district (borough), metropolitan area of South Yorkshire, England, occupying 225 square miles (582 square km) in the eastern third of the county. At its heart lies historic Doncaster town on the River Don on the site of a Roman station (Danum). In the Middle Ages, Doncaster grew as the market town of a rich agricultural district. Its first royal charter was granted in 1194. In the 19th century it became a major railway junction with large locomotive works. In the 20th century, as coal-mining employment has shifted eastward, it has grown as the service centre for the new mining communities and has acquired many new industries while retaining importance as an agricultural market. Its mansion house (1748) is one of three original mansion houses left in England. The St. Leger classic is run annually in September at the Doncaster racecourse. Pop. (1991) town, 71,595; (2001) district, 286,865.

Doncaster, James Scott, Earl of: see Monmouth, James Scott, Duke of.

Donders, Frans Cornelis (b. May 27, 1818, Tilburg, Neth.—d. March 24, 1889, Utrecht), ophthalmologist, the most eminent of 19th-century Dutch physicians, whose investigations of the physiology and pathology of the eye made possible a scientific approach to the correction of refractive disabilities such as nearsightedness, farsightedness, and astigmatism.

Donders' interest in ophthalmology began in 1847 with a study of *muscae volitantes*, the problem of specks seen floating before the eye. This study resulted in his formulation of what is now known as Donders' law: the rotation of the eye around the line of sight is involuntary.

As professor of physiology at the University of Utrecht (1852–89), Donders did research that immediately improved diagnosis, operative treatment, and use of eyeglasses to correct impairments of vision. He found (1858) that hypermetropia (farsightedness) is caused by a shortening of the eyeball, so that light

rays refracted by the lens of the eye converge behind the retina. He discovered (1862) that the blurred vision of astigmatism is caused by uneven and unusual surfaces of the cornea

Donders, engraving by H. Dilcher after a drawing by F. Kriehuber, c. 1860

Archiv für Kunst und Geschichte, Berlin

and lens, which diffuse light rays instead of focusing them. This last finding created the field of scientific clinical refraction.

Donders summarized his studies in *On the Anomalies of Accommodation and Refraction* (1864), the first authoritative work in the field.

Doneck (Ukraine): see Donetsk.

Donegal, Irish DÚN NA NGALL ("Fort of the Foreigners"), most northerly county of Ireland, bounded on the west and north by the Atlantic Ocean, on the east by Lough (lake) Foyle and Northern Ireland, and on the south by Northern Ireland and County Leitrim, Ireland. The small village of Lifford is the county seat. The rugged coast is heavily indented, in the north, with major inlets being Lough Swilly and Lough Foyle, between which is the Inishowen Peninsula. The chief rivers are the Finn and Erne. The main mountain ranges are the Blue Stack, whose highest peak is Lavagh More (2,218 feet [676 m]), and Derryveagh, its highest peak being Errigal (2,467 feet [752 m]). Evidence of extensive glaciation exists. The climate is temperate, with warm summers and mild, moist winters.

The name was extended from the town of Donegal to the county, which was made a shire in 1585. The ancient name was Tyrconnell ("Land of Conall"). Conall, with his brother Eoghan, conquered northwestern Ulster in approximately 400 and founded the kingdom of Ailech; its capital was at the concentric stone fortress known as the Grianan of Ailech on a hill west of Londonderry, N.Ire. Eoghan took Tyrone and Inishowen for his share, and his descendants, the O'Neills, ruled central Ulster. Conall took Tyrconnell, in which his descendants, the O'Donnells, ruled. The remoteness of these areas enabled them to escape serious interference from the Anglo-Normans. Following the defeat of the Irish cause in 1603, however, Hugh O'Neill and Rory O'Donnell took flight secretly to the European continent in 1607. The county was immediately included in the plan for the plantation of Ulster, and its history thereafter merged with that of Ireland.

Donegal's population is concentrated largely along the coasts and river valleys; the main towns are Donegal, Buncrana, Ballyshannon, and Letterkenny. The county, with the exception of the urban districts, is administered by a county council and county manager. The Foyle and Finn basins are intensively cultivated, but the rugged western seaboard is unsuitable for cultivation. Agriculture consists of tillage and rearing of cattle, sheep, and poultry; the chief crops are oats and potatoes. Killybegs on the southwest coast is the main fishing port and a fish-processing cen-

tre. Salmon are caught in the Rivers Finn, Foyle, Erne, and Gweebarra. Tourism is important and is based on the scenery, the many beaches, and the golf courses. In west Donegal, which remains an Irish-speaking region, woolen garments are made by hand, and, at Convoy, Donegal tweeds are woven. Recent industrial development includes the manufacture of carpets, fishing nets, synthetic fibres, and garments. No railway serves Donegal. Area 1,865 square miles (4,830 square km). Pop. (1991) 128,117.

Donegal, Irish DÚN NA NGALL ("Fort of the Foreigners"), seaport and market town, County Donegal, Ireland, on the River Eske at the head of Donegal Bay. It is famed for its historic associations and picturesque environs.

Ruins of the Franciscan Donegal Abbey, Donegal, Ire.

The Office of Public Works—Ireland

South of the town are the ruins of the Franciscan Donegal Abbey (founded 1474). Donegal Castle, a stronghold of the O'Donnells, was rebuilt in the early 17th century. The town is noted for its handwoven tweed. Pop. (1991) 2,193.

Donelaitis, Kristijonas, also spelled KRISTIJONAS DUONELAITIS (b. Jan. 1, 1714, near Gumbinnen, East Prussia [now Gusev, Russia]—d. Feb. 18, 1780, Tolmingkehmen [now Chistyve Prudy]), Lutheran pastor and poet who was one of the greatest Lithuanian poets and one of the first to be appreciated outside his country.

Donelaitis studied theology and classical languages at the University of Königsberg (1736–40) and in 1743 became pastor of the village of Tolmingkehmen, where he remained until his death.

His main work, *Metai* (1818; *The Seasons*), 2,997 lines in length, was written in hexameters, which were never before used in Lithuanian verse. It depicts realistically and in their own dialect the life of the serfs and the countryside of 18th-century Prussian Lithuania. The poem was first published in an incomplete edition with a German translation (*Das Jahr in vier Gesängen*; "The Year in Four Cantos") by Ludwig Rhesa in Königsberg in 1818. It has been translated into several other languages. Donelaitis' other literary works include six fables and a tale in verse, *Pričkaus pasaka apie lietuvišką svodbę* (1865; "Pričkaus Tale about a Lithuanian Wedding").

Donelson, Fort, in the American Civil War, important Confederate stronghold at Dover, Tenn., that was captured by Union forces on Feb. 16, 1862, forcing a general Southern withdrawal along the Confederate western line of defense in Kentucky from Columbus to Bowling Green. Fort Donelson was an entrenched camp erected by Confederate forces to guard the lower Cumberland River and the water approach to Nashville. On Feb. 12, 1862, Union General Ulysses S. Grant moved on the fort using the same combined army and navy tactics that had resulted in his capture of Fort Henry on the Tennessee River six days earlier. Failing to break through the entrenched Union positions, the South elected to give up the defense. Although 3,000

Confederate troops escaped, 15,000 men under General Simon B. Buckner were surrendered unconditionally. The fall of Fort Henry and Fort Donelson opened the way by river into Tennessee and forced the evacuation of such Southern strongholds as Columbus and Nashville.

Donen, Stanley (b. April 13, 1924, Columbia, S.C., U.S.), American motion-picture director and choreographer whose inventive dance sequences infused musicals with a fresh vitality in the 1940s and '50s.

Donen began his career in New York City in the stage chorus of *Pal Joey* (1940), where he met Gene Kelly. Later, as an assistant dance director in Hollywood, he collaborated with Kelly on several spirited musicals. He helped

choreograph such films as *Cover Girl* (1944) and *Anchors Aweigh* (1945) and then in 1949 codirected *On the Town*, which was hailed as a major landmark in the evolution of musical comedy. Successfully blending reality and fantasy, it introduced a vivid showmanship to the genre. The two men also did *Singin' in the Rain* (1952), which combined dance parodies of choreographer Busby Berkeley and comic satire in a classic about early talkies, and *It's Always Fair Weather* (1955).

Without Kelly, Donen directed and produced other successes such as *Seven Brides for Seven Brothers* (1954), *Funny Face* (1957), *The Pajama Game* (1957), and *Damn Yankees* (1958). In the late 1950s he moved to Europe, where he made such films as *Indiscreet* (1958), *Charade* (1963), *Arabesque* (1966), *Bedazzled* (1967), *Two for the Road* (1967), and *Movie Movie* (1978).

Donets Basin, Ukrainian DONETSKYY BASEYN, Russian DONETSKY BASSEYN, by-name DONBAS, or DONBASS, large mining and industrial region of southeastern Europe, notable for its large coal reserves. The coalfield lies in Luhansk and Donetsk oblasti (provinces), southeastern Ukraine, and in the adjoining Rostov oblast of southwestern Russia. The principal exploited area of the field covers nearly 9,000 square miles (23,300 square km) south of the Donets River, but coal deposits also extend westward to the Dnieper River in the greater Donets Basin. During the 1960s some exploitation began in this western extension, especially in eastern Dnipropetrovsk oblast. Coal was first discovered in the Donets Basin in 1721, but exploitation did not begin until the early 19th century and became significant only after the first railway reached the area in 1869. Development in the last two decades of the 19th century was rapid, and by 1913 the Donets Basin was producing 87 percent of Russian coal. Despite erosion of its relative position by the development of new coalfields and despite setbacks in World War I, in the Russian Civil War following the October Revolution (1917), and in World War II, absolute coal production continued to increase until the 1970s. Annual production declined from 221.5 million tons in 1975 to 198.7 million tons in 1985, and due to equip-

ment shortages and strikes, output declined further to 139.4 million tons in 1992. The region has more than 100 mining communities.

The Donets Basin still has large coal reserves, much of it of high quality. Proved reserves total 50.3 billion tons, with a further 63.5 billion tons probable reserves and 76.2 billion tons possible. Of the proved reserves, about one-fourth are anthracite, concentrated chiefly at the eastern end of the field. The coal occurs in some 300 coal-bearing seams. A difficulty of the field is that seams are thin, averaging just under 3 feet (1 m), and only 40 are thick enough to be worked economically. Most thicker seams and those nearer the surface have been worked out, and mining is now deep. The average mining depth is 1,150–1,300 feet (350–400 m).

After several largely unsuccessful efforts to establish a metallurgical industry on the coalfield, an ironworks was set up in 1872 by a Welshman, John Hughes. During the 1880s the Donets Basin developed into the principal iron- and steel-producing region of the country; by 1913 it was making 74 percent of all Russian pig iron. World War II caused heavy damage to plants and towns but led to postwar reconstruction with larger and more modernized enterprises. The area remains the largest single producing area of iron and steel in Ukraine and is one of the world's major metallurgical and heavy-industrial complexes. Iron ore is obtained from Kryvyi Rih to the west and from Kerch in the Crimea; manganese is mined at Nikopol and Marganets on the Dnieper. The chief iron- and steel-producing towns of the basin, together with Luhansk, Kramatorsk, and other centres, have a range of large heavy-engineering industries. The chemical industry is well developed, based on coking by-products and rock salt mined in the Donets Basin near Artemivsk; the main chemical towns are Artemivsk and Slov'yansk. Mercury is also mined in the Donets Basin, and cement making is important. In modern times, a wide range of light and consumer-goods industries have been introduced to diversify the economy and to supply the needs of the large urban populations.

Donets River, Russian SEVERSKY DONETS, Ukrainian SIVERSKYI DONETS, a tributary of the Don River, southwestern Russia and eastern Ukraine. The Donets is 650 miles (1,050 km) long and drains a basin of 39,000 square miles (100,000 square km). Rising in the Central Russian Upland, it flows south past Belgorod, Russia; enters Ukraine and passes to the east of Kharkiv; swings southeastward and eventually reenters Russia; and then turns south to join the Don below Konstantinovsk. The river is frozen from early December to late March. It follows a course along the north of the Donets Basin industrial region, which uses much of its water and causes severe pollution problems. A water shortage in the river and industrial area led to the construction in the 1970s of a canal carrying additional supplies from the Dnieper to the Donets. Six weirs make navigation possible upstream to Donetsk in Rostov *oblast* (province).

Donetsk, also spelled DONECK, formerly (1938–61) STALINO, *oblast* (province) in the southeastern part of Ukraine. Formed in 1938 as Stalino *oblast*, it stretches from the Donets Hills in the north, across the low, gently rolling Azov Upland and the level coastal plain, to the Sea of Azov. There is little surface water in this relatively dry region, and many of the smaller streams even dry out in summer; this, together with the heavy pollution of the Donets River, poses serious problems of water supply for industrial and domestic needs. The whole *oblast* is in fertile steppeland, and the greater part is under the plow. The *oblast* (headquarters at Donetsk city) includes the western half of the Donets Basin coalfield and associated industrial area, a factor reflected in the excep-

tionally high proportion (90 percent) of urban dwellers living in some 50 towns. Despite the overwhelming predominance of coal mining, iron and steel manufacture, heavy engineering, and chemicals in the economy, the *oblast* is important agriculturally, chiefly for winter wheat, corn (maize), and sunflowers. Market gardening is highly developed around the towns. Area 10,200 square miles (26,500 square km). Pop. (1998 est.) 5,064,400.

Donetsk, also spelled DONECK, formerly (until 1924) YUZOVKA, or (1924–61) STALINO, city and administrative centre of Donetsk *oblast* (province), southeastern Ukraine, on the headwaters of the Kalmius River. In 1872 an ironworks was founded there by a Welshman, John Hughes (from whom the town's pre-Revolutionary name Yuzovka was derived), to produce iron rails for the growing Russian rail network. Later steel rails were made. The plant used coal from the immediate vicinity, and both coal mining and steel making developed rapidly. By 1914 there were 4 metallurgical plants, 10 coal pits, and a population of about 50,000. After the October Revolution (1917), Yuzovka was renamed Stalino and, in 1961, Donetsk. Today the city has a large ethnic Russian population. Heavy destruction in World War II led to postwar modernization and an increase in industry, which resulted in substantial and sustained economic growth. Coal has been Donetsk's dominant industry, though it has undergone some decline. The centre of the iron and steel industry is the Donetsk Metallurgical Plant. Coke by-products are the basis of a chemical industry producing plastics. There are several heavy-engineering works, and light and food industries are also important. Manufactures include clothing, cotton cloth, footwear, furniture, and refrigerators.

The necessity of avoiding areas subject to subsidence caused by mining has led to a patchy development of the densely built-up residential and factory areas and open spaces over the extensive area of the town's administrative limits (162 square miles [420 square km]). The principal street, from the railway station to the steelworks, is 5.5 miles (9 km)

Donetsk, Ukraine

long, with the main shops, hotels, and administrative buildings. There are a university; polytechnic, medical and trade institutes; and more than 30 scientific research establishments, including a branch of the Academy of Sciences of Ukraine. Cultural amenities include several theatres and a philharmonic hall. Pop. (1998 est.) 1,065,400.

Dong (people): *see* Tung.

Dong Hai, Wade-Giles TUNG HAI, English EAST CHINA SEA, arm of the Pacific Ocean and part of the China Sea (*q.v.*).

Dong Nai River, also called DONNAI RIVER, Vietnamese SONG DONG NAI, river rising in the central highlands (Annamese Cordillera) of southern Vietnam, northwest of Da Lat. Near its source the river has rapids and is known as the Da Dung River. It flows west and southwest for about 300 miles (480 km), joining the Saigon River southwest of Bien

Hoa. At the rapids of Tri An, west of Dinh Quan, it is joined by the Be River. The Nhim, an important upper tributary, rises northeast of Da Lat on the Lam Vien Plateau and has three sets of rapids and falls. Two of the cascades, Lien Khuong and Gu Gau, are below Phi Mum; the third, Pongour, just west of the Nhim's junction with the Dong Nai, has been harnessed for hydroelectric power. The Dong Nai, or Donnai, gave its name to the Upper Donnai (Haute Donnai) province and plateau region of French colonial Vietnam.

Dong Qichang (Chinese artist): *see* Tung Ch'i-ch'ang.

Dong Son culture, important prehistoric culture of Indochina; it is named for a village in northern Vietnam where many of its remains have been found. The Dong Son site shows that bronze culture was introduced into Indochina from the north, probably about 300 BC, the date of the earliest Dong Son remains. Dong Son was not solely a bronze culture; its people also had iron implements and Chinese cultural artifacts. Nevertheless, their bronze work, especially the production of ritual bronze kettle drums, was of a high order. The Dong Son people also are distinguished by their great stone monuments, built for religious functions, which are similar to monuments found in Polynesia.

The Dong Son were a seafaring people who apparently traveled and traded throughout Southeast Asia. They also cultivated rice and are credited with originating the process of changing the Red River delta area into a great rice-growing region. The Dong Son culture, transformed by further Chinese and then Indian influence, became the basis of the general civilization of the region. Remnants of the culture have been found dating from as late as the 16th century, though most of it disappeared after the region was conquered by China in the 2nd century BC.

Dong Zhongshu (Confucian philosopher): *see* Tung Chung-shu.

Dongan, Thomas, 2ND EARL OF LIMERICK (b. 1634, Castletown, County Kildare, Ire.—d. Dec. 14, 1715, London, Eng.). British colonial governor of New York under Charles II and James II.

A Roman Catholic and a member of a royalist family, Dongan was exiled after the English Civil Wars (1642–51) and served in an Irish regiment of the French army. Recalled to England in 1677, he served as lieutenant governor of Tangier from 1678 to 1680. As governor of New York (1682–88), he called the colony's first representative assembly, issued a "Charter of Liberties" providing for religious toleration, and pursued a policy of cooperation with the Iroquois Confederacy against the French. Dongan returned to England in 1691 and succeeded his brother as Earl of Limerick in 1698.

Dongbei (China): *see* Manchuria.

Dongen, Kees van, in full CORNELIS THEODORUS MARIE VAN DONGEN (b. Jan. 26, 1877, Delfshaven, Neth.—d. May 28, 1968, Monte Carlo, Monaco), Dutch-born French painter, one of the leading Fauvists after Henri Matisse, particularly renowned for his sensuously rendered portraits of women.

Van Dongen exhibited artistic leanings early in his youth. He attended the Royal Academy of Fine Arts of Rotterdam and moved to Paris at the age of 20. In the bohemian atmosphere of the Montmartre district, he worked as a house painter, an illustrator for satirical papers, and a café artist.

Having made the acquaintance of Matisse, he participated in 1905 in the famous Salon d'Automne, at which the Fauve (Wild Beast)

group was given its epithet. In 1907 he was contracted by Daniel Henry Kahnweiler, the dealer of Picasso, and his reputation grew.

In 1908 he was invited to join the German Expressionist group Die Brücke (The Bridge), centred at the time in Dresden. Van Dongen's candid, colouristic portrait style was immensely fashionable by the end of World War I. The figure of the thin, red-lipped, unmistakably aristocratic woman (as in "Woman with Jewels," 1905) became his rather chilling archetype. His portrait of Anatole France (1917) is particularly notable. He also painted numerous richly coloured seascapes and scenes of Paris in an assured, economical style.

Donglin (Chinese group): see Tung-lin.

Dongola (The Sudan): see Dunqulah.

Dongting Hu (China): see Tung-t'ing Lake.

Dönitz, Karl (b. Sept. 16, 1891, Grünau bei-Berlin, Ger.—d. Dec. 22, 1980, Aumühle, W.Ger.), German naval officer and creator of Germany's World War II U-boat fleet who for a few days succeeded Adolf Hitler as German head of state.

During World War I, Dönitz served as a submarine officer in the Black Sea and the Mediterranean. In the aftermath of Hitler's accession to power, despite the Versailles Treaty's absolute ban on German submarine construction, Dönitz clandestinely supervised the creation of a new U-boat fleet, over which he was subsequently appointed commander (1936). In the midst of World War II, in January 1943, he was called to replace Adm. Erich Raeder as commander in chief of the German Navy. His loyalty and ability soon won him the confidence of Hitler. On April 20, 1945, shortly before the collapse of the Nazi regime, Hitler appointed Dönitz head of the northern military and civil command. Finally—in his last political testament—Hitler named Dönitz his successor as president of the *Reich*, minister of war, and supreme commander of the armed forces. Assuming the reins of government on May 2, 1945, Dönitz retained office for only a few days. In 1946 he was sentenced to 10 years' imprisonment by the International Military Tribunal at Nürnberg. He was released from prison in 1956 and retired on a government pension. His memoirs were published in 1958.

Donizetti, (Domenico) Gaetano (Maria) (b. Nov. 29, 1797, Bergamo, Cisalpine Republic—d. April 8, 1848, Bergamo, Lombardy, Austrian Empire), Italian opera composer whose numerous operas in both Italian and French represent a transitional stage in operatic development between Rossini and Verdi.

Donizetti, portrait by Giovanni Carnevali; in the Museo Donizettiano, Bergamo, Italy

By courtesy of the Museo Donizettiano, Bergamo, Italy

Among his major works are *Lucia di Lammermoor* (1835), *La fille du régiment* (1840), and *La favorite* (1840). In his serious operas he developed considerably the dramatic weight and emotional content of the genre, and his comic operas have a sparkling wit and gaiety all their own.

Early life. The youngest of three sons of the caretaker of the *monte di pietà* (the municipal pawnshop), Donizetti began his musical studies with Giovanni Simone Mayr, a Bavarian priest who was musical director of Sta. Maria Maggiore, Bergamo's chief church, and also a successful composer of opera. As a choirboy Donizetti did not shine, but Mayr perceived in him a nascent musical ability and secured his entry into the Liceo Filarmonico (the music school) at Bologna, where he had a thorough training in fugue and counterpoint. His father hoped he would become a church composer, but, though he did compose a vast quantity of sacred music, his natural instinct was for the theatre.

Donizetti scored his first success with *Enrico di Borgogna*, which first appeared in 1818 at the Teatro San Luca, in Venice, and during the next 12 years he composed no fewer than 31 operas, most of them produced at Naples and now forgotten. In 1830 his *Anna Bolena*, produced in Milan, carried his fame abroad to all the European capitals and eventually across the Atlantic. Two years later he scored another lasting success with *L'elisir d'amore* (*The Elixir of Love*), a comedy full of charm and character with a libretto by Felice Romani, the best theatre poet of the day. *Lucrezia Borgia* (1833), also with a libretto by Romani, consolidated his reputation at La Scala in Milan and elsewhere. Like the opera composers Gioacchino Rossini and Vincenzo Bellini before him, he next gravitated to Paris, where his *Marino Faliero*, though not a failure, suffered from comparison with Bellini's *I Puritani*, produced a few weeks before. Donizetti then returned to Naples for the production of his tragic masterpiece, *Lucia di Lammermoor*, on Sept. 26, 1835.

In 1828 Donizetti had married Virginia Vasseli, the sister of one of his closest friends in Rome; they made their home in Naples. He was deeply devoted to her and never really recovered his spirits after her death, soon after the stillbirth of a son, in 1837. His distress was exacerbated by the fact that none of the three children born to them survived birth. It seems clear that syphilis, to which Donizetti himself later succumbed, was already taking its toll of his family.

Success in Paris. Donizetti continued to work in Naples until 1838, when municipal censors objected to the production of his *Poliuto*, which dealt with a Christian martyr, on the ground that the sacred subject was unsuitable for the stage. He thereupon returned to Paris, where the field had been cleared for him by Bellini's early death and Rossini's retirement. There he revived some of his best operas, though *Lucrezia Borgia* had to be withdrawn because of objections by Victor Hugo, on whose drama the libretto was based. *Poliuto* was produced in 1840 as *Les Martyrs* with a French text by Eugène Scribe. It was preceded two months earlier by the opéra comique *La fille du régiment* (*The Daughter of the Regiment*), which gained enormous popularity over the years through the performances of the leading sopranos of the day, including Jenny Lind, Adelina Patti, Marcella Sembrich, Emma Albani, and other divas of the 19th century. Later in the same year the Paris Opéra produced *La favorite*, Donizetti's first essay in French grand opera.

Bartolomeo Merelli, a fellow pupil of Donizetti, was now director of La Scala and also of the Kärnthner Theater, in Vienna. He engaged Donizetti to compose an opera for La Scala. The work, *Maria Padilla*, was

produced in 1841 only a few weeks before the famous premiere of Verdi's *Nabucco*. Merelli also commissioned an opera for his Viennese theatre. There, *Linda di Chamounix*, a romantic *opera semiseria*, was produced in 1842 and dedicated to the empress Maria Anna. Donizetti had already been brought to the notice of the emperor Ferdinand I by his chancellor, Prince Metternich, and had conducted Rossini's *Stabat Mater* in his presence. He now received the appointment of official composer to the Emperor, which obliged him to be in Vienna for six months in the year but left him free to work elsewhere during the rest. At the same time Rossini, who had always furthered Donizetti's interests in Paris and entrusted to him the first performance of his *Stabat Mater* at Bologna, urged him to undertake the vacant directorship of the Liceo in that city. But Donizetti felt that he could not undertake this responsibility and preferred to continue his profitable operatic career. Back in Paris, he produced at the Théâtre Italien the delightful and witty comic opera, *Don Pasquale*.

Physical breakdown. But Donizetti was already in the grip of his fatal disease. He produced his last important opera, *Dom Sébastien*, with a libretto by Scribe, at the Paris Opéra in 1843 under the strain of constant headaches and occasional lapses of mental capacity. He suddenly aged, lost his good looks and his equability of temper, which had hitherto seen him through the trials of operatic production. *Dom Sébastien*, though unfavourably reviewed in the press, was nonetheless a success with the public.

The remaining years were a story of degeneration into hopeless insanity. As a patient in a private asylum near Paris, he had considerable difficulties with the French police, who were supported by the doctors; he was at last taken home to Bergamo by his devoted nephew Andrea, son of his eldest brother. He lingered on until April 8, 1848, a victim of general paralysis of the syphilitic insane, deprived of willpower, speech, and physical control. It was a pitiable end for a gay and handsome man who, unlike Bellini, was never envious of the successes of other composers and at all times displayed an openhearted generosity. To the French composer Hector Berlioz, for example, whose criticisms in *Le Journal des Débats* were consistently hostile, he spontaneously sent a letter of introduction to Prince Metternich, when Berlioz was about to leave for Vienna.

Donizetti always won more favour with the public than with the critics. During his lifetime his success was enormous and the rewards considerable. His popularity continued until the end of the century, but by 1914 his operas had almost disappeared from the repertory, overshadowed by the more substantial masterpieces of Verdi and Richard Wagner. In the 1950s there was a revival of interest in his works, after which it seemed unlikely that, at least, *Lucia di Lammermoor*, *L'elisir d'amore*, and *Don Pasquale* would be allowed to pass into oblivion. (D.Hus.)

MAJOR WORKS. Operas. 75 including *Alfredo il Grande* (1823); *Emilia di Liverpool* (1824); *Le convenienze e le inconvenienze teatrali* (1827); *Il borgomastro di Sardaam* (1827); *La regina di Golconda* (1828); *Il giovedì grasso* (1828); *Il castello di Kenilworth* (after Scott, 1829); *Anna Bolena* (1830); *L'elisir d'amore* (1832); *Il furioso all'isola di San Domingo* (1833); *Torquato Tasso* (1833); *Lucrezia Borgia* (1833); *Maria Stuarda* (1834); *Gemma di Vergy* (1834); *Marino Faliero* (after Byron, 1835); *Lucia di Lammermoor* (after Scott, 1835); *Belisario* (1836); *Il campanello di notte* (1836); *Beily* (1836); *Pia de' Tolomei* (1837); *Roberto d'Evereux, Conte d'Essex* (1837); *Poliuto* (1840); *La fille du régiment* (1840); *La favorite* (1840); *Linda di Chamounix* (1842); *Don Pasquale* (1843); *Maria di Rohan* (1843); *Dom Sébastien, roi de Portugal* (1843).

Other works. Two oratorios, several cantatas, religious pieces, at least 20 string quartets, three string quintets, and numerous songs.

BIBLIOGRAPHY. Detailed studies of the man and his works are Herbert Weinstock, *Donizetti and the World of Opera in Italy, Paris, and Vienna in the First Half of the Nineteenth Century* (1963, reprinted 1979), a comprehensive biography; and William Ashbrook, *Donizetti* (1965), and *Donizetti and His Operas* (1982).

donkey, also called **BURRO**, domestic ass belonging to the horse family, Equidae, and descended from the African wild ass (*Equus asinus*; see *ass*). It is known to have been used as a beast of burden since 4000 BC. The average donkey stands 101.6 cm (40 inches) at the shoulder, but different breeds vary greatly. The Sicilian donkey reaches only about 61 cm, while the large ass of Majorca stands at about 157.5 cm, and the American ass has been measured to 167.6 cm. In colour the donkey ranges from white to gray or black and usually has a dark stripe from mane to tail and a crosswise stripe on the shoulders. The mane is short and upright and the tail, with long hairs only at the end, is more cowlike than horse-like. The very long ears are dark at the base and tip. Although slower than horses, donkeys are surefooted and can carry heavy loads over rough terrain. The mule (*q.v.*) is a hybrid, the offspring of the mating of a male (jackass, or jack) donkey and a female horse.

Although the names donkey and burro are interchangeable, the term burro is widely used in the southwestern United States to describe small donkeys, *burro* being the word for donkey in the Spanish language. Feral donkeys, found in various parts of the world, are descendants of escaped or abandoned domestic animals. In the western United States, many authorities consider that the large population of feral burros is driving the desert bighorn sheep to extinction by competing for the limited resources of its very arid habitat.

donkey orchid, any of about 38 species of terrestrial plants, family Orchidaceae, that constitute the genus *Diuris*. One species is found in Java; the others are native to Australia. A donkey orchid has grasslike leaves. The two upper petals on each flower resemble the ears of a donkey, and the greenish lateral sepals are long and drooping. The common donkey orchid (*Diuris longifolia*) bears from three to five flowers about 4 cm (1.5 inches) long. Other well-known species are cat's face (*D. filifolia*) and nanny-goat orchid (*D. laevis*).

Donkin, Bryan (b. March 22, 1768, Sandree, Northumberland, Eng.—d. Feb. 27, 1855, London), developer of a commercial application of the so-called Fourdrinier machine for making paper and inventor of the composition roller used in printing.

While serving as an apprentice to a papermaker, John Hall, in Dartford, Kent, Donkin was engaged to perfect a papermaking machine that had been devised in 1798 by Nicolas-Louis Robert of France and later patented in England by Henry and Sealy Fourdrinier. He completed the first practical Fourdrinier machine at Frogmore Mill, Hertfordshire, about 1803 and in subsequent years constructed 191 more.

In 1812, using the ideas of the French inventor Nicolas-François Appert, who had devised a method for preserving food in stoppered bottles, he established a factory to produce and can vegetable soups and preserved meats for the Royal Navy. A year later Donkin and a printer developed a forerunner of the rotary press and a composition printing roller. Because the old flatbed press that moved back and forth could not print fast enough to produce large numbers of newspapers, the inventors arranged four trays, each containing a page of type, on the four sides of a revolving spindle. An important feature of the new machine was the use of inking rollers made of

glue and treacle (composition). Although this machine eventually failed, composition rollers were widely adopted. After 1815 Donkin became a civil engineer in London, received two gold medals from the Society of Arts, and was a founder (1818) of the Institution of Civil Engineers.

Donleavy, J.P., in full **JAMES PATRICK DONLEAVY** (b. April 23, 1926, Brooklyn, N.Y., U.S.), American-born author of the lusty comic novel *The Ginger Man* (Paris, 1955; U.S., 1958), which introduced Dangerfield, a coarse, comic anti-hero. Donleavy is noted for his characters who display heroism in the face of a mad universe and remain deeply attached to life despite its flaws.

Donleavy served with the U.S. Navy during World War II, studied microbiology at Trinity College, Dublin, and became an Irish citizen in 1967. *A Singular Man* (1963), *The Saddest Summer of Samuel S.* (1966), and later works continued to develop the prose style of *The Ginger Man*, which is distinguished by alliteration and an original treatment of voice. Action occurs in the third person while thoughts are conveyed in the first, allowing the character to speak both as observer and observed. Donleavy's later works include *The Onion Eaters* (1971), *A Fairy Tale of New York* (1973), *The Destinies of Darcy Dancer*, *Gentleman* (1977), *Schultz* (1979), and *Leila* (1983).

Dönme, also spelled **DÖNMEH** (Turkish: "Convert"), Jewish sect founded in Salonika (now Thessaloniki, Greece) in the late 17th century, after the conversion to Islām of Shabbetai Tzevi, whom the sectarians believed to be the Messiah. The Dönme, who numbered about 15,000 in the late 20th century, are found primarily in Istanbul, Edirne, and Izmir, Turkey.

Shabbetai Tzevi had proclaimed himself the Messiah in 1648 and quickly gained financial support and a considerable following among Jews throughout the Holy Land, Europe, and North Africa. Early in 1666 he was arrested by Ottoman Turks and, faced with the choice of conversion or death, accepted Islām by the end of the year. The Dönme believed that the conversion of Shabbetai Tzevi was a step in the fulfillment of the messianic prophecy. They therefore also converted to Islām but secretly practiced various Judaic rites. Although they remained apart from the larger Jewish community, they preserved some knowledge of Hebrew, kept secret Hebrew names, forbade intermarriage with the Muslim population, and conducted their marriage and funeral rites in secret. As the Dönme remained secretive and lived in separate quarters, they were not generally noticed by the Muslims. Internally they split into a number of subjects, reflecting social distinctions and disputes over the successors to Shabbetai.

At the turn of the 20th century, the Dönme, well represented in the professional classes, took active part in the Young Turk movement and the revolution of 1908. After the Greco-Turkish War of 1921–22, the central Dönme community of Thessaloniki was moved to Istanbul, and a gradual process of assimilation set in. Contact with Jews was lost, and the Dönme themselves resisted Jewish attempts to return them to Judaism.

Donnai River (Vietnam): see *Dong Nai River*.

Donnan, Frederick George (b. Sept. 5, 1870, Colombo, Ceylon [now Sri Lanka]—d. Dec. 16, 1956, Canterbury, Kent, Eng.), British chemist whose work was instrumental in the development of colloid chemistry.

Donnan was educated at Queen's College in Belfast, N.Ire., and at the Universities of

Leipzig, Berlin, and London. From 1904 to 1913 he taught at the University of Liverpool, and from 1913 to his retirement in 1937 he was professor of chemistry at University College, London.

In 1911 Donnan studied the conditions under which equilibrium is established between two electrolytic solutions separated by a semipermeable membrane—that is, by a membrane through which the solvent and some, but not all, of the dissolved ions can pass. In the absence of such a membrane, the solvent and every species of dissolved ion will diffuse freely from each solution into the other, until the composition of the two solutions becomes the same. The semipermeable membrane, however, prevents the transfer of at least one ionic species, and the preservation of electrical neutrality limits the diffusion of that species' oppositely charged partner. Nevertheless, some movement of mobile ions does occur, and the compositions of the solutions change; as a result, the final distribution of the ionic species is unequal, and there is a measurable difference in the electric potential of the solutions on each side of the membrane. The nature of the equilibrium and the existence of the potential have both become associated with Donnan's name.

Donnay, Maurice (-Charles) (b. Oct. 12, 1859, Paris, France—d. March 31, 1945, Paris), French playwright whose dramas deal with love and adultery, social problems, and the manners of his time.

Donnay was born into a wealthy family and originally trained to be a civil engineer. His dramatic career began with monologues written for the literary cabaret Le Chat-Noir. He made his name in the theatre with *Amants* (1895; "Lovers"), one of his best plays and the first work of a series called "Théâtre d'Amour," which also includes *La Douleoureuse* (1897)

Donnay
Haringue—H. Roger-Viollet

and *L'Affranchie* (1898), both of which are dramas about women whose loves are spoiled by lies. A second cycle of plays, including *Le Retour de Jérusalem* (1903) and *Les Éclaircissements* (1913), deals with current social problems; and another group of plays, including *La Chasse à l'homme* (1919) and *La Reprise* (1924), are comedies of manners, depicting France after World War I.

Among Donnay's other works are several autobiographical publications, including *Mon Journal, 1919-30* (1953). Donnay's *Théâtre* was published in 8 volumes (1908–27).

Donne, John (b. sometime between Jan. 24 and June 19, 1572, London, Eng.—d. March 31, 1631, London), leading English poet of the Metaphysical school and dean of St. Paul's Cathedral, London (1621–31). Donne is often considered the greatest love poet in the English language. He is also noted for his religious

verse and treatises and for his sermons, which rank among the best of the 17th century.

Life and career. Donne was born of Roman Catholic parents. His mother, a lineal descendant of Sir Thomas More, was the youngest daughter of John Heywood, epigrammatist

Donne, detail of an oil painting by an unknown artist after I. Oliver, c. 1616; in the National Portrait Gallery, London
By courtesy of the National Portrait Gallery, London

and playwright. His father, who, according to Donne's first biographer, Izaak Walton, was "descended from a very ancient family in Wales," was a prosperous London merchant. Donne was four when his father died, and shortly thereafter his mother married Dr. John Syminges, who raised the Donne children. At age 12 Donne matriculated at the University of Oxford, where he studied for three years, and he then most likely continued his education at the University of Cambridge, though he took no degree from either university because as a Roman Catholic he could not swear the required oath of allegiance to the Protestant queen, Elizabeth. Following his studies Donne probably traveled in Spain and Italy and then returned to London to read law, first at Thavies Inn (1591) and then at Lincoln's Inn (1592–94). There he turned to a comparative examination of Roman Catholic and Protestant theology and perhaps even toyed with religious skepticism. In 1596 he enlisted as a gentleman with the Earl of Essex's successful privateering expedition against Cádiz, and the following year he sailed with Sir Walter Raleigh and Essex in the near-disastrous Islands expedition, hunting for Spanish treasure ships in the Azores.

After his return to London in 1597, Donne became secretary to Sir Thomas Egerton, lord keeper of the great seal, in whose employ Donne remained for almost five years. The appointment itself makes it probable that Donne had become an Anglican by this time. During his tenure with the lord keeper, Donne lived, according to Walton, more as a friend than as a servant in the Egerton household, where Sir Thomas appointed him "a place at his own table, to which he esteemed [Donne's] company and discourse to be a great ornament." Donne's contemporary, Richard Baker, wrote of him at this time as "not dissolute [*i.e.*, careless], but very neat; a great visitor of Ladies, a great frequenter of Plays, a great writer of conceited Verses."

While in Egerton's service, Donne met and fell in love with Anne More, niece of Egerton's second wife and the daughter of Sir George More, who was chancellor of the garter. Knowing there was no chance of obtaining Sir George's blessing on their union, the two married secretly, probably in December 1601. For this offense Sir George had Donne briefly imprisoned and dismissed from his post with

Egerton as well. He also denied Anne's dowry to Donne. Because of the marriage, moreover, all possibilities of a career in public service were dashed, and Donne found himself at age 30 with neither prospects for employment nor adequate funds with which to support his household.

During the next 10 years Donne lived in poverty and humiliating dependence, first on the charity of Anne's cousin at Pyrford, Surrey, then at a house in Mitcham, about 7 miles (11 km) from London, and sometimes in a London apartment, where he relied on the support of noble patrons. All the while he repeatedly tried (and failed) to secure employment, and in the meantime his family was growing; Anne ultimately bore 12 children, 5 of whom died before they reached maturity. Donne's letters show his love and concern for his wife during these years: "Because I have transplanted [her] into a wretched fortune, I must labour to disguise that from her by all such honest devices, as giving her my company, and discourse." About himself, however, Donne recorded only despair: "To be part of no body is as nothing; and so I am. . . I am rather a sickness or a disease of the world than any part of it and therefore neither love it nor life."

In spite of his misery during these years, Donne wrote and studied assiduously, producing prose works on theology, canon law, and anti-Catholic polemics and composing love lyrics, religious poetry, and complimentary and funerary verse for his patrons. As early as 1607 friends had begun urging him to take holy orders in the Church of England, but he felt unworthy and continued to seek secular employment. In 1611–12 he traveled through France and the Low Countries with his new-found patron, Sir Robert Drury, leaving his wife at Mitcham. Upon their return from the European continent, the Drurys provided the Donnes with a house on the Drury estate in London, where they lived until 1621.

In 1614 King James I refused Donne's final attempt to secure a post at court and said that he would appoint him to nothing outside the church. By this time Donne himself had come to believe he had a religious vocation, and he finally agreed to take holy orders. He was ordained deacon and priest on Jan. 23, 1615, and preferment soon followed. He was made a royal chaplain and received, at the king's command, the degree of doctor of divinity from Cambridge. On Nov. 22, 1621, Donne was installed as dean of St. Paul's Cathedral, at which he carried out his duties with efficiency and integrity. But this turnabout in Donne's professional life was accompanied by searing personal grief. Two years after his ordination, in 1617, Anne Donne died at the age of 33 after giving birth to a stillborn child. Grief-stricken at having lost his emotional anchor, Donne vowed never to marry again, even though he was left with the task of raising his children in modest financial circumstances at the time. Instead, his bereavement turned him fully to his vocation as an Anglican divine. The power and eloquence of Donne's sermons soon secured for him a reputation as the foremost preacher in the England of his day, and he became a favourite of both Kings James I and Charles I.

In 1623 Donne fell seriously ill with either typhus or relapsing fever, and during his sickness he reflected on the parallels between his physical and spiritual illnesses—reflections that culminated during his recovery in the prose *Devotions upon Emergent Occasions*, published in 1624. On Feb. 25, 1631, Donne, who was fatally ill with stomach cancer, left his sickbed to preach a final sermon at court; this was published posthumously as "Death's Duell" and is sometimes considered to be his own funeral sermon. He returned to his sickbed and, according to Walton, had a drawing made of himself in his shroud, perhaps as

an aid to meditating on his own dissolution. From this drawing Nicholas Stone constructed a marble effigy of Donne that survived the Great Fire of 1666 and still stands today in St. Paul's Cathedral.

Poetry. Because almost none of Donne's poetry was published during his lifetime, it is difficult to date it accurately. Most of his poems were preserved in manuscript copies made by and passed among a relatively small but admiring coterie of poetry lovers. Most current scholars agree, however, that the elegies (which in Donne's case are poems of love, not of mourning), epigrams, verse letters, and satires were written in the 1590s, the *Songs and Sonnets* from the 1590s until 1617, and the "Holy Sonnets" and other religious lyrics from the time of Donne's marriage until his ordination in 1615. He composed the hymns late in his life, in the 1620s. Donne's *Anniversaries* were published in 1611–12 and were the only important poetic works by him published in his lifetime.

Donne's poetry is marked by strikingly original departures from the conventions of 16th-century English verse, particularly that of Sir Philip Sidney and Edmund Spenser. Even his early satires and elegies, which derive from classical Latin models, contain versions of his experiments with genre, form, and imagery. His poems contain few descriptive passages like those in Spenser, nor do his lines follow the smooth metrics and euphonious sounds of his predecessors. Donne replaced their mellifluous lines with a speaking voice whose vocabulary and syntax reflect the emotional intensity of a confrontation and whose metrics and verbal music conform to the needs of a particular dramatic situation. One consequence of this is a directness of language that electrifies his mature poetry. "For Godsake hold your tongue, and let me love," begins his love poem "The Canonization," plunging the reader into the midst of an encounter between the speaker and an unidentified listener. Holy Sonnet XI opens with an imaginative confrontation wherein Donne, not Jesus, suffers indignities on the cross: "Spit in my face yee Jewes, and pierce my side. . ."

From these explosive beginnings, the poems develop as closely reasoned arguments or propositions that rely heavily on the use of the conceit—*i.e.*, an extended metaphor that draws an ingenious parallel between apparently dissimilar situations or objects. Donne, however, transformed the conceit into a vehicle for transmitting multiple, sometimes even contradictory, feelings and ideas. And, changing again the practice of earlier poets, he drew his imagery from such diverse fields as alchemy, astronomy, medicine, politics, global exploration, and philosophical disputation. Donne's famous analogy of parting lovers to a drawing compass affords a prime example. The immediate shock of some of his conceits aroused Samuel Johnson to call them "heterogeneous ideas . . . yoked by violence together." Upon reflection, however, these conceits offer brilliant and multiple insights into the subject of the metaphor and help give rise to the much-praised ambiguity of Donne's lyrics.

The presence of a listener is another of Donne's modifications of the Renaissance love lyric, in which the lovers lament, hope, and dissect their feelings without facing their ladies. Donne, by contrast, speaks directly to the lady or some other listener. The latter may even determine the course of the poem, as in "The Flea," in which the speaker changes his tack once the woman crushes the insect on which he has built his argument about the innocence of lovemaking. But for all their dramatic intensity, Donne's poems still maintain the verbal music and introspective approach that define lyric poetry. His speakers may fashion an imaginary figure to whom they utter their lyric outburst, or, conversely, they may lapse into reflection in the midst of an

address to a listener. "But O, selfe traytor," the forlorn lover cries in "Twickham Garden" as he transforms part of his own psyche into a listener. Donne also departs from earlier lyrics by adapting the syntax and rhythms of living speech to his poetry, as in "I wonder by my troth, what thou, and I/Did, till we lov'd?". Taken together, these features of his poetry provided an impetus for the works of such later poets as Robert Browning, William Butler Yeats, and T.S. Eliot.

Donne also radically adapted some of the standard materials of love lyrics. For example, even though he continued to use such Petrarchan conceits as "parting from one's beloved is death," a staple of Renaissance love poetry, he either turned the comparisons into comedy, as when the man in "The Apparition" envisions himself as a ghost haunting his unfaithful lady, or he subsumed them into the texture of his poem, as the title "A Valediction: forbidding Mourning" exemplifies. Donne's love lyrics provide keen psychological insights about a broad range of lovers and a wide spectrum of amorous feelings. His speakers range from lustful men so sated by their numerous affairs that they denounce love as a fiction and women as objects—food, birds of prey, mummies—to platonic lovers who celebrate both the magnificence of their ladies and their own miraculous abstention from consummating their love. Men whose love is unrequited feel victimized and seek revenge on their ladies, only to realize the ineffectuality of their retaliation. In the poems of mutual love, however, Donne's lovers rejoice in the compatibility of their sexual and spiritual love and seek immortality for an emotion that they elevate to an almost religious plane.

Donne's devotional lyrics, especially the "Holy Sonnets," "Good Friday 1613, Riding Westward," and the hymns, passionately explore his love for God, sometimes through sexual metaphors, and depict his doubts, fears, and sense of spiritual unworthiness. None of them shows him spiritually at peace.

The most sustained of Donne's poems, the *Anniversaries*, were written to commemorate the death of Elizabeth Drury, the 14-year-old daughter of his patron, Sir Robert Drury. These poems subsume their ostensible subject into a philosophical meditation on the decay of the world. Elizabeth Drury becomes, as Donne noted, "the Idea of a woman," and a lost pattern of virtue. Through this idealized feminine figure, Donne in *The First Anniversarie: An Anatomie of the World* laments humanity's spiritual death, beginning with the loss of Eden and continuing in the decay of the contemporary world, in which men have lost the wisdom that connects them to God. In *The Second Anniversarie: Of the Progres of the Soule*, Donne, partly through a eulogy on Elizabeth Drury, ultimately regains the wisdom that directs him toward eternal life.

Prose. Donne's earliest prose works, *Paradoxes and Problems*, probably were begun during his days as a student at Lincoln's Inn. These witty and insouciant paradoxes defend such topics as women's inconstancy and pursue such questions as "Why do women delight much in feathers?" and "Why are Courtiers sooner Atheists than men of other conditions?" While living in despair at Mitcham in 1608, Donne wrote a casuistic defense of suicide entitled *Biathanatos*. His own contemplation of suicide, he states, prompted in him "a charitable interpretation of their Action, who dye so." Donne's *Pseudo-Martyr*, published in 1610, attacks the recusants' unwillingness to swear the oath of allegiance to the king, which Roman Catholics were required to do after the Gunpowder Plot (1605). The treatise so pleased James I that he had Oxford confer an honorary master of arts degree on Donne. In 1610 Donne also wrote a prose satire on the Jesuits entitled *Ignatius His Conclave*, in both Latin and English.

In 1611 Donne completed his *Essays in Divinity*, the first of his theological works. Upon recovering from a life-threatening illness, Donne in 1623 wrote *Devotions upon Emergent Occasions*, the most enduring of his prose works. Each of its 23 devotions consists of a meditation, an expostulation, and a prayer, all occasioned by some event in Donne's illness, such as the arrival of the king's personal physician or the application of pigeons to draw vapours from Donne's head. The *Devotions* correlate Donne's physical decline with spiritual sickness, until both reach a climax when Donne hears the tolling of a passing bell (16, 17, 18) and questions whether the bell is ringing for him. Like Donne's poetry, the *Devotions* are notable for their dramatic immediacy and their numerous Metaphysical conceits, such as the well-known "No man is an Island," by which Donne illustrates the unity of all Christians in the mystical body of Christ.

It is Donne's sermons, however, that most powerfully illustrate his mastery of prose. One-hundred and fifty-six of them were published by his son in three great folio editions (1640, 1649, and 1661). Though composed during a time of religious controversy, Donne's sermons—intellectual, witty, and deeply moving—explore the basic tenets of Christianity rather than engage in theological disputes. Donne brilliantly analyzed Biblical texts and applied them to contemporary events, such as the outbreak of plague that devastated London in 1625. The power of his sermons derives from their dramatic intensity, candid personal revelations, poetic rhythms, and striking conceits.

Reputation and influence. The first two editions of Donne's *Poems* were published posthumously, in 1633 and 1635, after having circulated widely in manuscript copies. The *Poems* were sufficiently popular to be published eight times within 90 years of Donne's death, but his work was not to the general taste of the 18th century, when he was regarded as a great but eccentric "wit." The notable exception to that appraisal was Alexander Pope, who admired Donne's intellectual virtuosity and echoed some of Donne's lines in his own poetry. From the early 19th century, however, perceptive readers began to recognize Donne's poetic genius. Robert Browning credited Donne with providing the germ for his own dramatic monologues. By the 20th century, mainly because of the pioneering work of the literary scholar H.J.C. Grierson and the interest of T.S. Eliot, Donne's poetry experienced a remarkable revival.

The impression in his poetry that thought and argument are arising immediately out of passionate feeling made Donne the master of both the mature Yeats and Eliot, who were reacting against the meditative lyricism of a Romantic tradition in decline. Indeed, the play of intellect in Donne's poetry, his scorn of conventionally poetic images, and the dramatic realism of his style made him the idol of English-speaking poets and critics in the first half of the 20th century. Readers continue to find stimulus in Donne's fusion of witty argument with passion, his dramatic rendering of complex states of mind, his daring and unhackneyed images, and his ability (little if at all inferior to William Shakespeare's) to make common words yield up rich poetic meaning without distorting the essential quality of English idiom. (P.G.Pi.)

BIBLIOGRAPHY. R.C. Bald, *John Donne: A Life*, ed. by W. Milgate (1970, reprinted with corrections 1986), remains the definitive biography. An older but still valuable biography is Edmund Gosse (compiler), *The Life and Letters of John Donne*, 2 vol. (1899, reprinted 1959). John Carey, *John Donne: Life, Mind, and Art*, new ed. (1990), intertwines interpretations of Donne's writings and his life. Good introductions to the poetry are Wilbur Sanders, *John Donne's Poetry* (1971); Clay

Hunt, *Donne's Poetry: Essays in Literary Analysis* (1954, reissued 1969); Arnold Stein, *John Donne's Lyrics: The Eloquence of Action* (1962, reprinted 1980); and Patricia Garland Pinka, *This Dialogue of One: The Songs and Sonnets of John Donne* (1982). M. Thomas Hester, *Kinde Pity and Brave Scorne: John Donne's Satyres* (1982), offers an extended analysis of these early poems. A fine introduction to the prose is Evelyn M. Simpson, *A Study of the Prose Works of John Donne*, 2nd ed. (1948, reissued 1962). Kate Garther Frost, *Holy Delight: Typology, Numerology, and Autobiography in Donne's Devotions upon Emergent Occasions* (1990), offers a comprehensive analysis of Donne's most popular prose.

Donnelly, Ignatius (b. Nov. 3, 1831, Philadelphia, Pa., U.S.—d. Jan. 1, 1901, Minneapolis, Minn.). American novelist, orator, and social reformer, one of the leading advocates of the theory that Francis Bacon was the author of William Shakespeare's plays.

Donnelly grew up in Philadelphia, where he became a lawyer. In 1856 he moved to Minnesota, where, with another ex-Philadelphian, John Nininger, he founded the boomtown Nininger City, intended as a cultural as well as an industrial centre. There he edited the erudite *Emigrant Aid Journal*, published in both English and German, to attract settlers. The scheme was successful at first, but a financial panic in 1857 caused abandonment of the town, leaving Donnelly as its only resident.

He entered politics, became an early supporter of the Republican Party, and served as lieutenant governor of Minnesota and as a U.S. congressman from 1863 to 1869. He left the Republicans in the 1870s and was active in several minority-party movements representing the interests of small farmers and workmen. Returning to Nininger City, he edited a liberal weekly, the *Anti-Monopolist*, in which he attacked bankers and financiers, whom he regarded as public enemies. His first and most popular book was *Atlantis* (1882), which traced the origin of civilization to the legendary submerged continent of Atlantis. It was followed in 1883 by another work of speculation, *Ragnarok: The Age of Fire and Gravel*, which attempted to relate certain gravel and till deposits to an ancient near-collision of the Earth and a huge comet. In *The Great Cryptogram* (1888) and *The Cipher in the Plays and on the Tombstone* (1899), he attempted to prove that Bacon was the author of the plays attributed to Shakespeare by deciphering a code he discovered in Shakespeare's works. His deciphering also led him to ascribe the plays of Christopher Marlowe and the essays of Michel de Montaigne to Bacon. Donnelly's utopian novel *Caesar's Column* (1891), which predicted such developments as radio, television, and poison gas, portrays the United States in 1988 ruled by a ruthless financial oligarchy and peopled by an abject working class. It enhanced Donnelly's reputation with the Populist Party, which represented the discontented farmers of the West and which he helped found in 1892. At the time of his death, he was vice presidential candidate of a splinter party, the Middle Road Populists.

Donner, Georg Raphael (b. May 24, 1693, Esslingen, Austria—d. Feb. 15, 1741, Vienna), sculptor whose works marked the transition from the Baroque to the Neoclassical style.

In Heiligenkreutz in his youth to take holy orders, Donner met the sculptor Giovanni Giuliani and was encouraged to take up sculpture, working in Giuliani's studio and later entering the Vienna Academy. He lived in Salzburg for some years, later returning to Vienna, where he produced his masterpiece, the "Providence Fountain" on the Neuer Markt (New Market; 1738–39). The figures originally cast in lead, a technique favoured by

the artist, were replaced in 1873 by copies in bronze. Other Donner works are the Perseus and Andromeda fountain in the courtyard of the Vienna Rathaus and a statue of Emperor Charles VI in the Belvedere, Vienna. The re-

Bronze figure from the Neuer Markt fountain, Vienna, by Georg Raphael Donner, 1739; in the Österreichische Galerie, Vienna

By courtesy of the Österreichische Galerie, Vienna, photograph, Photo Meyer

fined form and clear outline of his sculpture contrasted with the exaggerated Baroque style of his contemporaries and predecessors and influenced his followers to adopt more classical conceptions.

Donner Pass, pass, in the Sierra Nevada of northern California, U.S., at an altitude of 7,085 ft (2,160 m), 35 mi (56 km) west-southwest of Reno, Nev. During the winter of 1846–47, George and Jacob Donner lost almost half of a party of more than 80 immigrants when they tried to cross the pass en route to the Sacramento Valley. The party was blocked by snow in the Sierra Nevada and, when their food ran out, some survived by eating the corpses of their fallen companions. The pass now represents the most important transmontane route (rail and highway) connecting San Francisco with Reno. It lies within the Tahoe National Forest, and Donner Memorial State Park is nearby.

Dono, Paolo di (Florentine painter): *see* Uccello, Paolo.

Donoso, José (b. Oct. 5, 1924, Santiago, Chile—d. Dec. 7, 1996, Santiago), Chilean novelist and short-story writer important in the development of the Latin American new novel.

After studying at the Pedagogical Institute of Santiago for three years, he completed his studies at Princeton University, where he received the B.A. degree in 1951. He taught at the Catholic University of Chile and the University of Chile in the 1950s and toward the end of the decade began to work as a journalist. After lecturing at the University of Iowa (1965–67) he took up residence in Spain. His short-story collection *Veraneo y otros cuentos* ("Summer Vacation and Other Stories") was published in 1955. The short-story collection *El charleston* (*Charleston and Other Stories*, 1977) appeared in 1960.

Donoso's first novel, *Coronación* (1957; *Coronation*, 1965), established his reputation at home and abroad, and won him the William Faulkner Foundation Prize in 1962.

The novel presents the moral collapse of an aristocratic family and suggests that an insidious loss of values is prevalent in all sectors of society. Donoso's second and third novels, *Este domingo* (1966; *This Sunday*, 1967) and *El lugar sin límites* (1966; *Hell Has No Limits*, 1972), depicted characters barely able to subsist in an atmosphere of desolation and anguish.

Donoso's masterpiece, *El obsceno pájaro de la noche* (1970; *The Obscene Bird of Night*, 1973), made him world famous. In it he presented a hallucinatory, often grotesque, world and captured the fears, frustrations, dreams, and obsessions of his characters with profound psychological insight. *Historia personal del "boom"* (1972; *The Boom in Spanish American Literature: A Personal History*, 1977) is a series of essays interpreting the phenomenal success of the new Latin American novel. In the novella collection *Tres novelitas burguesas* (1973; "Three Bourgeois Novellas"; Eng. trans. *Sacred Families*, 1977) he employs fantastic elements to shed light on previously treated themes and situations. The novel *Casa de Campo* (1978; *A House in the Country*, 1984) examines in a Surrealist style the breakdown of social order in post-colonial Latin America.

Donoughmore Commission, committee sent by the British government to Ceylon in 1927 to examine the Ceylonese constitution and to make recommendations for its revision. The commission's recommendations, reluctantly accepted by Ceylonese political leaders, served as the basis for the new constitution of 1931.

Two of the most important reforms that were suggested concerned elections and electorates. The previous communal electorates, which had been intended to safeguard the rights of minority groups in Ceylon, were abolished. In their place territorial constituencies were substituted, on the grounds that the continued existence of communal electorates would encourage a spirit of divisiveness among the Ceylonese people. The minority groups were unhappy with this change. One of these groups, the Tamils, boycotted the first elections under the new constitution.

The new constitution also extended the franchise to all adults, with only a residence qualification (in order to exclude the many Indian migrant labourers in Ceylon). The middle-class Ceylonese political leaders were opposed to this provision, but the British felt that it would encourage these very leaders to pay more attention to the needs of the people. The third group of recommendations concerned the nature of the representative institutions to be established. An assembly, or state council (composed of territorially elected members), with both legislative and executive powers was established. This assembly was to have significant financial and revenue powers; but a number of important executive functions, such as management of the public service, defense, foreign affairs, and the administration of justice, were to be performed by three British officials nominated by the governor of Ceylon. Further, the governor was given wide veto powers over decisions of the assembly, although he was expected to use them with discretion. The new constitution, which endured until 1946, proved unsatisfactory to the Ceylonese and was, for its duration, the object of constant criticism.

Donovan, William J(oseph), byname **WILD BILL DONOVAN** (b. Jan. 1, 1883, Buffalo, N.Y., U.S.—d. Feb. 8, 1959, Washington, D.C.), American lawyer, soldier, and diplomat who directed (1942–45) the U.S. Office of Strategic Services (OSS) during World War II.

Donovan began the practice of law in Buffalo in 1907. In 1916 he served in the New York National Guard on the Mexican border, and in World War I he was in France with the

165th Infantry Regiment (formerly the celebrated New York 69th). He advanced to the rank of colonel and was awarded the Congressional Medal of Honor. In 1922 he was appointed U.S. district attorney for western New York. He served as assistant attorney general in the Justice Department from 1924 to 1929. During the 1930s he returned to the practice of law but maintained his political connections both in the United States and abroad. Pres. Franklin D. Roosevelt, in 1940–41, asked Donovan to draft plans for the creation of a central intelligence service for the United States. Donovan was appointed coordinator of information on July 11, 1941. On June 13, 1942, he was named chief of the newly created OSS. This military agency was charged with collecting foreign intelligence and carrying out counterpropaganda and covert action operations; it conducted operations throughout the world, except for Latin America and Gen. Douglas MacArthur's Pacific command, and was most active in Europe.

Donovan was made a brigadier general in 1943. Although he was foremost among the advocates of a peacetime central intelligence service, he declined any role in the Central Intelligence Agency (CIA), which was created in 1947. He served as U.S. ambassador to Thailand in 1953–54.

Donus, also spelled **DOMNUS** (b. Rome—d. April 11, 678, Rome), pope from 676 to 678. Elected (August 676) to succeed Adeodatus II, Donus ended a schism created by Archbishop Maurus of Ravenna (whose plan was to make Ravenna ecclesiastically independent) by receiving the obedience of Maurus' successor Reparatus. Donus is said to have dispersed the Monasterium Boetianum, a monastery of Syrian Nestorians. Noted for his restoration of churches, he was buried in St. Peter's.

Dooārs (India): *see* Duārs.

doodle, absent-minded scrawl or scribble, usually executed in some unexpected place, such as the margin of a book or manuscript or a blotting pad when the doodler is preoccupied with some other activity, such as attending a meeting or lecture. The word is supposed to have gained currency because of its use in the film *Mr. Deeds Goes to Town* (1936), though the practice of course is much older, doodles being found in medieval manuscripts, as well as in the notebooks of Leonardo da Vinci and on the margins of manuscripts written by Fyodor Dostoyevsky.

The increasing preoccupation in the 20th century with manifestations of the unconscious and the desire to interpret them both as art forms and as clues to the nature of personality have led to considerable interest in doodles. The Surrealist method of automatic drawing was used by Max Ernst, Salvador Dalí, and André Masson, and Jackson Pollock, an Abstract Expressionist, did a series of drawings that were used as an element in his psychoanalysis. *See also* graffiti.

Dooley, Thomas Anthony (b. Jan. 17, 1927, St. Louis, Mo.—d. Jan. 18, 1961, New York City), "jungle doctor" whose lectures and books recounted his efforts to supply medical aid to peoples of less developed countries, mainly in Southeast Asia.

A graduate of St. Louis University medical school (M.D., 1953), he was serving with the U.S. Navy as a medical officer when the end of French rule in Indochina in 1954 resulted in an independent but divided Vietnam. Volunteering for duty in the American effort to evacuate refugees from North to South Vietnam, Dooley instituted rigorous public-health measures and organized the processing of more than 600,000 Vietnamese for evacuation between September 1954 and May 1955.

He published a popular account of the operation, *Deliver Us from Evil* (1956), and left active service to lecture in the United States. He

used proceeds from lectures and book sales to establish a small hospital in Nam Tha, northern Laos. After another American lecture tour and the publication of *The Edge of Tomorrow* (1958), Dooley helped found the Medical International Corporation (Medico) to provide medical teams and hospital facilities in eight less-developed nations, most of them in Southeast Asia.

Dooley was highly regarded in the United States, but some of his colleagues in Asia regarded him as an egotist who allowed medical services to deteriorate while he engaged in self-promotion. He wrote *The Night They Burned the Mountain* (1960) to answer such criticism. He returned to Laos from the United States after surgery for a malignant tumour in 1959, but he did not survive a recurrence of the illness.

Doolin, Bill, byname of WILLIAM DOOLIN (b. 1863—d. 1896, Oklahoma, U.S.), Western outlaw who led a gang through robberies in Oklahoma and east Texas, 1892–95.

A member of the Dalton brothers (*q.v.*) gang, he alone missed the bloody ambush of the Coffeyville, Kan., bank robbery (Oct. 5, 1892); his horse had pulled lame long before reaching town. Thereafter, he built his own gang, robbing stagecoaches, banks, and trains. One by one, lawmen tracked the members down. Doolin, escaping arrest in 1895, tried to retire to a small Oklahoma farm; the next year he was discovered by Marshal Heck Thompson and shotgunned to death.

Doolittle, Hilda, byname H.D. (b. Sept. 10, 1886, Bethlehem, Pa., U.S.—d. Sept. 27, 1961, Zürich, Switz.), American poet, known initially as an Imagist. She was also a translator, novelist-playwright, and self-proclaimed “pagan mystic.”

Doolittle's father was an astronomer at the University of Pennsylvania, and she was reared in the strict Moravian tradition of her mother's family. She went to Europe in 1911 and remained abroad, except for brief visits, for the remainder of her life. William Carlos Williams was an early acquaintance, and, while at Bryn Mawr in 1905–06, she met and, for a brief time, became engaged to Ezra Pound. She was married to Richard Aldington from 1913 to 1938. Her friends included D.H. Lawrence, Marianne Moore, T.S. Eliot, Amy Lowell, the Sitwells, and Bryher (Winifred Ellerman), with whom she had a lifelong association.

H.D.'s first book of poetry, *Sea Garden* (1916), was followed by *Hymen* (1921), *Heliodora and Other Poems* (1924), *Red Roses for Bronze* (1929), and *Trilogy* (1944–46). The *Collected Poems of H.D.* (1925 and 1940), *Selected Poems of H.D.* (1957), and *Collected Poems 1912–1944* (1983) secured her position as a major 20th-century poet. She won additional acclaim for her translations (*Choruses from the Iphigenia in Aulis and the Hippolytus of Euripides* [1919] and *Euripides' Ion* [1937]), for her verse drama (*Hippolytus Temporizes* [1927]), and for such prose works as *Palimpsest* (1926), *Hedylus* (1928), and *The Gift* (1982). Several of her books were autobiographical—including *Bid Me to Live* (1960), *Tribute to Freud* (1974), and *End to Torment* (1979).

BIBLIOGRAPHY. Barbara Guest, *Herself Defined: The Poet H.D. and Her World* (1984), is an authorized biography. Janice S. Robinson, *H.D.: The Life and Work of an American Poet* (1982), concentrates more on literary analysis. Susan Stanford Friedman, *Psyche Reborn: The Emergence of H.D.* (1981), is a psychological study.

Doolittle, James H., in full JAMES HAROLD DOOLITTLE, byname JIMMY DOOLITTLE (b. Dec. 14, 1896, Alameda, Calif., U.S.—d. Sept. 27, 1993, Pebble Beach, Calif.), American aviator and army general who led an air raid on Tokyo and other Japanese cities four months after the Japanese attack on Pearl Harbor.

Doolittle was educated at Los Angeles Junior

College (1914–16) and the University of California School of Mines (1916–17). As an army enlistee during World War I, he became an expert aviator and flight instructor. He stayed in the Army Air Corps after the war, was promoted to first lieutenant in 1920, and also studied at the Massachusetts Institute of Technology (Cambridge, Mass.), where in 1925 he received a doctorate in advanced engineering.

Doolittle remained in the Army Air Corps until 1930, demonstrating, testing, and racing aircraft. Upon resigning his commission, he took charge of the aviation department of the Shell Oil Company. While serving as a consultant to the government and the military, he continued to race aircraft, setting a world high-speed record in 1932.

With the outbreak of World War II, Doolittle returned to active duty in the Army Air Forces. On April 18, 1942, he commanded a bombing mission that began on the deck of the aircraft carrier *Hornet*. Sixteen B-25s struck Tokyo, Yokohama, and other Japanese cities. The planes then proceeded westward, and most of the crews arrived safely behind friendly lines on the Chinese mainland. While the raid did little damage, it greatly bolstered U.S. morale and caused the Japanese to shift precious resources to air defense.

Doolittle, made a brigadier general after the raid, received the Congressional Medal of Honor for his actions and soon was promoted to major general. He continued to lead air operations during the war, on the European, North African, and Pacific fronts, winning promotion to lieutenant general in 1944. He commanded the 8th Air Force in its attacks on Germany during 1944–45. After the war he returned to Shell Oil and to advisory positions in both the public and private sectors, remaining active in the aerospace industry after retiring in 1959. He received the Presidential Medal of Freedom in 1989.

DOON DE MAYENCE, hero baron of the medieval epic poems in Old French known as *chansons de geste*, which together form the core of the Charlemagne legends. Doon's story is told in a chanson belonging to a cycle called *Geste de Doon de Mayence*. This cycle tells of Charlemagne's rebellious barons and contains the stories of heroes such as Girart de Roussillon, Raoul de Cambrai, Renaud de Montauban, and Ogier the Dane, all of whom are represented as opposing Charlemagne (though the emperor's name is probably often used to stand for his weaker successor, Louis). The chanson dealing with Doon himself first gives a romantic account of his childhood; the second half, describing his wars in Saxony, may have a historical basis.

door, barrier of wood, stone, metal, glass, paper, leaves, hides, or a combination of materials, installed to swing, fold, slide, or roll in order to close an opening to a room or building. Early doors, used throughout Mesopotamia and the ancient world, were merely hides or textiles. Doors of rigid, permanent materials appeared simultaneously with monumental architecture. Doors for important chambers were often made of stone or bronze.

Stone doors, usually hung on pivots, top and bottom, were often used on tombs. A marble, paneled example, probably from the time of Augustus, was found at Pompeii; a Greek door (c. AD 200) from a tomb at Langaza, Turkey, has been preserved in the museum at Istanbul.

The use of monumental bronze doors is a tradition that has persisted into the 20th century. The portals of Greek temples were often fitted with cast-bronze grills; the Romans characteristically used solid bronze double doors. They were usually supported by pivots fitted into sockets in the threshold and lintel. The earliest large examples are the 24-foot (7.3-metre) double doors of the Roman Pantheon. The Roman paneled design and

mounting technique continued in Byzantine and Romanesque architecture. The art of casting doors was preserved in the Eastern Empire, the most notable example being double doors (c. 838) of the Hagia Sophia cathedral in Constantinople (now Istanbul). In the 11th century bronze castings from Constantinople were imported into southern Italy. Bronze doors were introduced into northern Europe, notably in Germany, when Charlemagne installed a Byzantine pair (cast c. 804) for the cathedral at Aachen. The first bronze doors to be cast in one piece in northern Europe were made for the Cathedral of Hildesheim (c. 1015). They were designed with a series of panels in relief, establishing a sculptural tradition of historical narrative that distinguishes Romanesque and, later, bronze doors.

Hollow casting of relief panels was revived in the 12th century in southern Italy, notably by Barisanus of Trani (cathedral doors, 1175), and carried northward by artists such as Bonanno of Pisa. In 14th-century Tuscany the principal examples are the pairs of sculptured, paneled bronze doors on the Florentine Baptistery; the Gothic south doors (1330–36) are by Andrea Pisano, and the north doors (1403–24) by Lorenzo Ghiberti. Ghiberti's east doors (1425–52) have come to be known as the “Gates of Paradise” (“Porta del Paradiso”). Bronze doors with relief panels by Antonio Filarete were cast for St. Peter's Basilica, Rome. Bronze doors were not generally used in northwestern Europe until the 18th century. The first monumental bronze doors in the United States were erected in 1863 in the Capitol at Washington, D.C.

The wooden door was doubtless the most common in antiquity. Archaeological and literary evidence indicate its prevalence in Egypt and Mesopotamia. According to Pompeian murals and surviving fragments, contemporary doors looked much like modern wood-paneled doors; they were constructed of stilts (vertical beams) and rails (horizontal beams) framed together to support panels and occasionally equipped with locks and hinges. This Roman type of door was adopted in Islamic countries. In China the wooden door usually consisted of two panels, the lower one solid and the upper one a wooden lattice backed with paper. The traditional Japanese shoji was a wood-framed, paper-covered sliding panel.

The typical Western medieval door was of vertical planks backed with horizontals or diagonal bracing. It was strengthened with long iron hinges and studded with nails. In domestic architecture, interior double doors appeared in Italy in the 15th century and then in the rest of Europe and the American colonies. The paneled effect was simplified until, in the 20th century, a single, hollow-core, flush panel door has become most common.

There also are several types of specialized modern doors. The louvered (or blind) door and the screen door have been used primarily in the United States. The Dutch door, a door cut in two near the middle, allowing the upper half to open while the lower half remains closed, descends from a traditional Flemish-Dutch type. The half door, being approximately half height and hung near the centre of the doorway, was especially popular in the 19th-century American West.

Glazed doors, dating from the 17th century, first appeared as window casements extended to the floor. French doors (double glazed) were incorporated into English and American architecture in the late 17th and 18th centuries. At about this time, the French developed the mirrored door.

Other types of 19th- and 20th-century innovations include the revolving door, the folding door, the sliding door inspired by the Japanese shoji, the canopy door (pivoting at the top of

the frame), and the rolling door (of tambour-like construction), also opening to the top.

Door Peninsula, body of land, northeastern Wisconsin, U.S., between Green Bay and Lake Michigan. About 80 miles (130 km) long and 25 miles (40 km) wide at its base and tapering northward to a point, it is crossed east-west by a waterway at Sturgeon Bay. The peninsula includes Door county (formed 1851), comprising the northern area, Kewaunee (1852), and parts of Brown (1818) and Manitowoc (1836) counties at the base. Communities on the peninsula include Egg Harbor, Ellison Bay, Jacksonport, Baileys Harbor (oldest village in Door county, founded 1851), Ephraim, Fish Creek, Sister Bay, Sturgeon Bay, and Washington (on Washington Island, off the tip of the peninsula).

Door Peninsula, which was visited in the 17th century by French traders and missionaries, now is a year-round vacation area. Cherry-growing and tourism are the major industries. At the tip of the peninsula between Washington Island and the peninsula is a hazardous strait known as La Porte des Morts (French: "Death's Door"), whence the name of Door county and Door Peninsula.

Doorman, Karel (Willem Frederik Marie)

(b. April 23, 1889, Utrecht, Neth.—d. Feb. 27, 1942, Java Sea), Dutch rear admiral who commanded a combined American, British, Dutch, and Australian (ABDA) naval force on a virtual suicide mission in World War II. Its purpose was to halt the Japanese naval invasion of the Netherlands East Indies.

A navy officer since 1910, Doorman served first in the Netherlands East Indies; during and after World War I, he helped develop the Dutch naval air force. Returning to the East Indies in 1937 as commander of the naval air force, in 1940 he became commander of the entire Dutch fleet in the East Indies. On Feb. 25, 1942, he was appointed tactical commander of the combined ABDA fleet that was ordered by ABDA commander General Sir Archibald P. Wavell to defend the Java Sea against the Japanese invasion fleet. Though greatly outnumbered, his 13-ship fleet sank many Japanese ships in a futile attempt to stop the invasion of Java. Allied naval resistance collapsed, however, when he went down with his flagship, *De Ruyter*. His rallying cry, "Ik val aan, volgt mij" ("I attack, follow me," sometimes given as "All ships follow me"), served as a battle slogan during the remainder of World War II.

Doornik (Belgium): see Tournai.

doorstop, usually decorative and invariably heavy object used to prevent doors from swinging shut. Doorstops came into use about 1775 following the introduction of the rising butt, a type of door hinge designed to close a door automatically. Many took the form of figures of famous persons, such as Napoleon, Shakespeare, Wellington, Gladstone, and Disraeli. Animal forms were also popular.

The most common material used for making doorstops was metal, generally cast with a flat, normally hollow, back, but in some early examples cast in the round. Brass, usually lacquered, was popular until about 1850. Cast-iron stops were made from about 1820, and soon production in this material reached large proportions, paint or a bronzed finish being the usual decoration. A handle or some other means of lifting the stop easily were commonly incorporated in the design. Also known are doorstops in earthenware and a few in glass made in Bristol.

dopamine, also called HYDROXYTYRAMINE, a nitrogen-containing organic compound formed as an intermediate compound from dihydroxyphenylalanine (dopa) during the metabolism of the amino acid tyrosine. It is the precursor of the hormones epinephrine and norepinephrine. Dopamine also functions as a neurotransmitter—primarily by inhibiting the transmission of nerve impulses—in the substantia nigra, basal ganglia, and corpus striatum of the brain. A deficiency of dopamine results in Parkinson's disease (*q.v.*).

dopant, any impurity deliberately added to a semiconductor for the purpose of modifying its electrical conductivity. The most commonly used semiconductors are the elements silicon and germanium, which form crystalline lattices in which each atom shares one electron with each of its four nearest neighbours. If a small proportion of the atoms in such a lattice is replaced by atoms such as phosphorus or arsenic, which have five electrons available for bond formation, the extra electron of each foreign atom becomes available for electrical conduction; the semiconductor is said to be doped with phosphorus or arsenic, which are called donor atoms; and the semiconductor is classed as *n*-type (*n* for negative, because the charge carriers are electrons, which are negatively charged particles).

Doping with atoms such as gallium, which has only three electrons available, creates a positively charged defect, or hole, in the bonding arrangement. Conduction can occur by migration of the positively charged site through the crystal lattice, and a semiconductor doped with an atom of this type, an acceptor atom, is called *p*-type.

doppelgänger (German: "double goer"), in German folklore, a wraith or apparition of a living person, as distinguished from a ghost. The concept of the existence of a spirit double, an exact but usually invisible replica of

Doppelgänger theme shown in "How They Met Themselves," oil painting by Dante Gabriel Rossetti; in the Fitzwilliam Museum, Cambridge, Cambridgeshire

By courtesy of the Syndics of the Fitzwilliam Museum, Cambridge, Cambridgeshire

every man, bird, or beast, is an ancient and widespread belief. To meet one's double is a sign that one's death is imminent. The doppelgänger became a popular symbol of horror literature, and the theme took on considerable complexity. In *The Double* (1846), by Fyodor Dostoyevsky, for example, a poor clerk, Golyadkin, driven to madness by poverty and unrequited love, beholds his own wraith, who succeeds in everything at which Golyadkin has failed. Finally the wraith succeeds in disposing of his original. An earlier, well-known story

of a doppelgänger appears in the novel *Die Elixire des Teufels*, 2 vol. (1815–16; "The Devil's Elixir"), by the German writer of fantastic tales E.T.A. Hoffmann.

Doppler, Christian (b. Nov. 29, 1803, Salzburg, Austria—d. March 17, 1853, Venice), Austrian physicist who first described how the observed frequency of light and sound waves is affected by the relative motion of the source and the detector. This phenomenon became known as the Doppler effect.

Educated at the Polytechnical Institute in Vienna, Doppler became director of the Physical Institute and professor of experimental physics of the University of Vienna in 1850. His earliest writings were on mathematics, but in 1842 he published *Über das farbige Licht*

Doppler, lithograph by Franz Sir after a drawing by Anton Machek

By courtesy of the Bild-Archiv, Österreichische Nationalbibliothek, Vienna

der Doppelsterne ("Concerning the Coloured Light of Double Stars"), which contained his first statement of the Doppler effect. He theorized that since the pitch of sound from a moving source varies for a stationary observer, the colour of the light from a star should alter, according to the star's velocity relative to Earth.

Doppler effect, the apparent difference between the frequency at which sound or light waves leave a source and that at which they reach an observer, caused by relative motion of the observer and the wave source. This phenomenon is used in astronomical measurements, in Mössbauer effect studies, and in radar and modern navigation. It was first described (1842) by Austrian physicist Christian Doppler.

The following is an example of the Doppler effect: as one approaches a blowing horn, the perceived pitch is higher until the horn is reached and then becomes lower as the horn is passed. Similarly, the light from a star, observed from the Earth, shifts toward the red end of the spectrum (lower frequency or longer wavelength) if the Earth and star are receding from each other and toward the violet (higher frequency or shorter wavelength) if they are approaching each other. The Doppler effect is used in studying the motion of stars and to search for double stars and is an integral part of modern theories of the universe. See also red shift.

Dor, also spelled DORA, modern settlement and ancient port in northwestern Israel, on the Mediterranean coast, south of Haifa. Ancient Dor was a strategic site on the Via Maris, the historic road that ran largely along the Palestine coast. Ruins found at the site date back to the Late Bronze Age (1500–1200 BC), and Dor is mentioned in Egyptian texts of the 11th century. It was an administrative division (Hebrew *napha*, or *nafa*) of Solomon's kingdom under the governorship of his son-in-law, Ben-abinadab (1 Kings 4:11). Passing to the northern Kingdom of Israel after Solomon's death, it was taken by the Assyrians (8th century), and later by the Persians; it was a possession of Ashmanezar, king of Sidon, a

Persian vassal. During the Hasmonean revolt, the city (the name of which had been Hellenized to Dora) was besieged by the Seleucid king Antiochus VII Sidetes (reigned 139/138–129 BC; I Maccabees 15:12–13, 25). Pompey took Dor in 64 BC and gave it civic autonomy. In ancient and classical times, Murex snails were hunted there for making the famous Tyrian purple dye. The port was rebuilt by the crusaders, who called it Chateau de Merle, but it was destroyed in 1291 after the Mamlūk conquest from Egypt.

The site was excavated in the 1920s and again in the 1950s; the ruins of the ancient harbour, amphitheatre, parts of a Byzantine church (6th century AD), and the crusader fort can be seen. The Arab village of Tanjūra on the site was taken by the Israel Defense Forces in May 1948; the modern Israeli settlement of Dor was established there the following year by Greek-Jewish immigrants. Just north is the kibbutz of Nahsholim, settled in 1948. Offshore are three rocky islets constituting an Israeli nature reserve. The Dor coast, with its fine beaches and hot springs, was developed as a tourist site. Pop. (latest est.) 177.

dorado (*Salminus maxillosus*), powerful game fish of the characin family, Characidae, found in South American rivers. The dorado is golden, with red fins and with lengthwise rows of dots on its body, and superficially resembles a salmon. It reaches a length of about 1

Dorado (*Salminus maxillosus*)

Painted especially for *Encyclopaedia Britannica* by Tom Dolan, under the supervision of Loren P. Woods, Chicago Natural History Museum

m (39 inches) and a weight of more than 18 kg (40 pounds).

The name dorado (Spanish for “golden”) is sometimes given to related species of *Salminus*; it is also another name for the dolphin and for oceanic fish of the family Coryphaenidae.

Dorat, Jean, Dorat also spelled DAURAT, Latin AURATUS (b. 1508, Le Dorat, near Limoges, Fr.—d. Nov. 1, 1588, Paris), French humanist, a brilliant Hellenist, one of the po-

Dorat, detail of a drawing by an unknown artist; in the Bibliothèque Nationale, Paris

Giraudon—Art Resource/EB Inc

ets of the Pléiade, and their mentor for many years.

Dorat belonged to a noble family; after studying at the Collège de Limoges, he became tutor to the pages of Francis I. He tutored Jean-Antoine de Baïf, whose father he succeeded as director of the Collège de Coqueret. There, besides Baïf, his pupils included Pierre de Ronsard, Rémy Belleau, and Pontus de Tyard. Joachim du Bellay was added to this group by Ronsard, and these five young poets, under the direction of Dorat, formed a society for the reform of French language and literature. They increased their number to seven

with the dramatist Étienne Jodelle and named themselves La Pléiade, in emulation of the seven Greek poets of Alexandria. The election of Dorat as their president proved his personal influence, but as a writer of French verse he is the least important of the seven.

Dorat stimulated his students to intensive study of Greek and Latin poetry, while he himself wrote incessantly in both languages. He is said to have composed more than 15,000 Greek and Latin verses.

His influence and fame as a scholar extended to England, Italy, and Germany. In 1556 he was appointed professor of Greek at the Collège Royal, a post that he held until he retired in 1567. He published a collection of the best of his Greek and Latin verse in 1586.

Dorati, Antal (b. April 9, 1906, Budapest—d. Nov. 13, 1988, Gerzensee, near Bern, Switz.). Hungarian-born American conductor notable for his promotion of 20th-century music, particularly that of Béla Bartók.

The son of musicians, he entered at age 14 the Liszt Academy in Budapest, where he studied with Bartók, Zoltán Kodály, and Leo Weiner. He read philosophy at Vienna University and upon graduation became a private coach at the Budapest Royal Opera. His conducting debut took place there in 1924. In 1928 he became assistant conductor of the Dresden Opera and in 1929 became musical director at Münster Opera. From 1933 to 1941 he conducted and toured extensively with the Ballets Russes de Monte Carlo.

After his American debut in 1937 with the National Symphony of Washington, D.C., Dorati developed a marked ability to build and reorganize orchestras. From 1941 to 1945 he was music director of the newly formed American Ballet Theater. He went on to conduct the Dallas Symphony Orchestra (1945–49), the Minneapolis Symphony Orchestra (1949–60), the BBC Symphony Orchestra (1963–66), the Stockholm Philharmonic (1966–70), the Washington National Symphony (1970–77), the Royal Philharmonic Orchestra (1975–78), and the Detroit Symphony Orchestra (1977–81). He became an American citizen in 1947. Dorati's many recordings include the complete Joseph Haydn symphonies (with the Philharmonia Hungarica). Throughout his career he broadened his orchestra's repertoires, promoting modern music and commissioning new works. *Notes of Seven Decades*, his autobiography, was published in 1979.

Dorchester, town (“parish”), West Dorset district, county of Dorset, England, on the River Frome.

The ancient town (then known as Durnovaria) was a sizable Roman British centre, and many remains of the period (including mosaics and ruined villas) have been found. In the south, an amphitheatre at Maumbury Rings dates from pre-Roman times; Maiden Castle (2 miles [3 km] southwest), a vast earth-

Trench and rampart of Maiden Castle, southwest of Dorchester, Dorset, England

The J. Allan Cash Photolibrary

work encircled by entrenchments and ramparts and occupying more than 120 acres (50 hectares), was the site of important settlement from Neolithic times into the Iron Age.

As early as the 10th century, the town had a mint. By 1086 it was a royal borough, and a castle had been built by the 12th century; the Franciscan priory, founded before 1331, is thought to have been constructed from its ruins. The first charter of incorporation was dated 1610. In 1834 the Tolpuddle martyrs were sentenced in the town for administering illegal oaths concerning trade union activities. The writer Thomas Hardy was born near Dorchester, the “Casterbridge” of his Wessex novels.

The cloth industry flourished in the 16th century, and serge was manufactured in the 17th. The town has been noted for its ale since the 1600s. Dorchester now functions as a market town and serves an extensive rural area. Agricultural machinery, printing, and leatherworking are local specialities. Pop. (1991) 15,037.

Dorchester (of Dorchester), Guy Carleton, 1st Baron (b. Sept. 3, 1724, Strabane, County Tyrone, Ire.—d. Nov. 10, 1808, Stubbings, Berkshire, Eng.), soldier-statesman who, as governor of Quebec before and during the American Revolutionary War, succeeded in reconciling the British and French and in repulsing the invasion attempts of Continental forces.

Carleton was commissioned an ensign in the British army in 1742, becoming a lieutenant colonel in 1757. Two years later he took part in the expedition against Quebec as quartermaster general under General James Wolfe; he was wounded at the Battle of the Plains of Abraham. After two years as lieutenant governor of the province of Quebec, Carleton became governor (1768–78). His conciliatory policy toward the French-Canadian landowners and clergy was confirmed by the British Parliament's enactment of the Quebec Act of 1774, which, though it postponed the advent of representative government in Quebec, later formed the basis for the French-Canadians' political and religious rights.

After helping to repel the Continental Army's invasion of Canada (1775–76), Carleton had a disagreement with the secretary of state for the colonies and retired. Four years later (in 1782) he was appointed commander in chief of British forces in North America. As governor in chief of British North America (1786–96), he promoted the Constitution Act of 1791, which helped develop representative institutions in Canada at a time when the French Revolution was threatening governments elsewhere. He retired to private life in England in 1796. He had been knighted in 1779 and created a baron in 1786.

Dordogne, département, Aquitaine région, southwestern France, created chiefly from the ancient *pays* (district) of Périgord. It has an area of 3,498 square miles (9,060 square km) and essentially comprises the limestone plateaus of the Petits Causses that rise gradually to the northeast where they meet the last outliers of the Massif Central at an elevation of about 1,300 feet (400 m). The valleys of the rivers flowing out of these highlands widen gradually as they descend to the west. The seven rivers of Dordogne, including the Isle, which crosses it from northeast to southwest, and the Dordogne, which gives it its name, have scenic valleys that support the cultivation of wheat, corn (maize), potatoes, tobacco, and fruit. Chestnut and oak predominate in its forests, and walnuts, about one-third of France's output, are grown extensively for oil. The climate in the valleys is mild and humid but more rigorous in the east.

The valley of the Vézère, in the southeast, is one of the earliest known cradles of human habitation. Caves at Les Eyzies-de-Tayac and Lascaux contain some of the world's best prehistoric drawings and paintings, although their preservation is now in question because of algal growth on the paintings resulting from the installation of lights for tourists. The number of châteaux—about 1,000—exceeds that of any other *département*. Many date from the 13th and 14th centuries, when the Dordogne was the frontier region in the wars between England and France. Medieval towns, including Périgueux (*q.v.*), the capital, Sarlat, and Brantôme, are among the most picturesque in France. The area is a centre of tourism and gastronomy (*e.g.*, the truffles of Périgord, the *pâté de foie gras*). There is some light industry (wood, paper, shoes) in the towns. The *département* is divided into four *arrondissements*—Périgueux, Bergerac, Nontron, and Sarlat—and is in the educational division of Bordeaux. Pop. (1982) 377,356.

Dordogne River, river in southwestern France, rising in the Massif Central and flowing west for 293 mi (472 km) to Bec d'Am-bès, north of Bordeaux, where it unites with the Garonne to form the Gironde Estuary; its drainage basin is about 9,300 sq mi (24,000 sq km). Its headwaters, rising at a height of more than 5,600 ft (1,700 m) on the Puy de Sancy, are formed by the Dore and Dognon rivers. After a torrential descent the Dordogne flows through the spa resorts of Le Mont Dore and La Bourboule, in the Puy de Dôme *département*. After passing through the Avèze gorges, the river forms a lake 11 mi (18 km) long above the hydroelectric dam of Bort. It is dammed again four more times as it flows through the Dordogne gorges to Argentat (Corrèze *département*), below which it is joined by a number of tributaries. Skirting Souillac (Lot *département*), it traverses the Dordogne *département*, where it receives the Vézère, on the banks of which are Montignac, Lascaux, and Les Eyzies-de-Tayac (famous for their prehistoric caves, which with other caves have become a classic ground for the study of Paleolithic man). Entering the Gironde *département*, the Dordogne receives the Isle at Libourne before flowing northwest to join the Garonne. There is much river traffic along the last 112 mi of its course.

Dordrecht, also called DORT, or DORDT, *gemeente* (municipality), Zuidholland *provincie* (province), southwestern Netherlands, at the divergence of the Merwede, Noord, Oude Maas (Old Meuse), and Dordtse Kil rivers. Founded in 1008, it was the residence of the counts of Holland until 1203 and was first chartered in 1220. It was fortified in 1271, and, although severely damaged by flood in 1421, it was one of the most prosperous medieval ports in the Netherlands until it was surpassed by Rotterdam and Amsterdam. In 1572 it was captured by the Sea Beggars (Netherlands rebels against Spain) and was the scene of the first assembly of the United Provinces. It was the seat (1618–19) of the important Synod of Dort, an international assembly of the Reformed Church (for which it had declared in 1572).

Many of its medieval houses, courtyards, gates (*e.g.*, Groothoofdspoort), quays, and canals have survived to contrast with spacious modern housing areas. The 14th-century Grote Kerk (Church of Our Lady) has a massive tower, finely carved choir stalls, and a notable pulpit. The 17th-century painters Aelbert Cuyp, Ferdinand Bol, and Nicolaes Maes were born in Dordrecht, and the town museums have collections of paintings by old Dutch masters and local medieval antiquities.

Johan de Witt, a 17th-century grand pensionary of Holland, and his brother Cornelis were natives of the town.

Still an active port, with a busy timber trade, Dordrecht has diversified industries that include shipbuilding, metallurgical and chemical works, and a large electric power station. It is also a centre for aquatic sports. Pop. (1983 est.) 107,612; Dordrecht-Zwijndrecht metropolitan area, 198,600.

Doré, (Paul-)Gustave (b. Jan. 6, 1832, Strasbourg, Fr.—d. Jan. 23, 1883, Paris), French printmaker, one of the most prolific and successful book illustrators of the late 19th century, whose exuberant and bizarre fantasy created vast dreamlike scenes widely emulated by Romantic academicians.

In 1847 he went to Paris and from 1848 to 1851 produced weekly lithographic caricatures for the *Journal pour Rire* and several albums of lithographs (1847–54). His later fame rested

Engraving from Dante's *Inferno* by Gustave Doré, 1861
By courtesy of the Bibliothèque Nationale, Paris

on his wood-engraved book illustrations. Employing more than 40 woodcutters, he produced over 90 illustrated books. Among his finest were an edition of the *Oeuvres de Rabelais* (1854), *Les Contes drolatiques* of Balzac (1855), the large folio Bible (1866), and the *Inferno* of Dante (1861). He also painted many large compositions of a religious or historical character and had some success as a sculptor; his work in those media, however, lacks the spontaneous vivacity of his illustrations.

Dorgan, Thomas Aloisius, pseudonym TAD (b. April 29, 1877, San Francisco—d. May 2, 1929, Great Neck, N.Y., U.S.), U.S. journalist, boxing authority, and cartoonist.

At an early age he joined the art department of the *San Francisco Bulletin*, where he worked as a cartoonist and comic artist. In 1902 he was employed by William Randolph Hearst, becoming a political cartoonist of the *New York Journal*. Dorgan did not continue as a political cartoonist, however, but began to concentrate his interests on sports, particularly boxing. His sketches of fighters and commentaries were widely syndicated throughout the country, his pen name Tad (the initials of his name) becoming well known.

Dorgan also developed comic-strip characters, such as "Silk Hat Harry" and "Judge Rummy," which he used in his daily cartoons.

Dorgan, temple name (Wade-Giles romanization) CH'ENG-TSUNG, canonized name (Wade-Giles) HUANG-TI (b. Nov. 17, 1612, Yenden, Manchuria—d. Dec. 31, 1650, Kharhotu), prince of the Manchu people of

Manchuria who played a major part in founding the Ch'ing (Manchu) dynasty in China. He was the first regent for the first Ch'ing emperor, Shun-chih.

Dorgan was the 14th of the 16 sons of Nurhachi, founder of the Manchu state, who in 1616 proclaimed himself emperor of China but died in 1626 before making good his claim to the Imperial title. Under his successor, Abahai (Nurhachi's eighth son), Dorgan received the title of an Imperial prince, *hosoi beile*. He distinguished himself in the wars against the Chahar Mongols that began in 1628 and was elevated to prince of the first degree (*jui ch'in-wang*). Dorgan commanded one of the two army groups that breached the Great Wall and sacked 40 cities in the Chinese provinces of Hopeh and Shantung during Abahai's campaigns to subjugate China in 1638–39. He also participated in the capture of the cities of Sung-shan and Chin-chou that resulted in a significant expansion of Manchu authority.

On Abahai's death in 1643, Dorgan was nominated his successor but declined, reportedly because of loyalty to the dead emperor. Instead, he and the older prince Jirgalang became regents for Abahai's five-year-old son, Fu-lin. The fact that Dorgan executed two princes when he discovered their plot to put him on the Imperial throne is characteristic of the high moral standards for which he is praised by historians.

When in April 1644 the troops of the Chinese rebel Li Tzu-ch'eng conquered Peking (the capital of China then ruled by the Ming dynasty), Dorgan, on the advice of a Chinese counsellor, led an expeditionary force into China. His former principal enemy, the Chinese general Wu San-kuei, joined forces with him rather than allow Li Tzu-ch'eng to establish his own dynasty, and the combined armies inflicted a heavy defeat on Li Tzu-ch'eng's troops. Dorgan entered Peking in June 1644, but the last Ming emperor had already hanged himself in April. After pursuing the fleeing troops of Li Tzu-ch'eng, Dorgan turned his attention to the stabilization of his administration, prudently enlisting the cooperation of several outstanding Chinese experts. He established Peking as the capital and, adopting many Chinese customs, laid the basis for Manchu rule in China.

The youthful Fu-lin entered Peking on Oct. 19, 1644, and 11 days later was proclaimed emperor (the first of the Ch'ing dynasty) under the name Shun-chih. In 1644 Dorgan subdued the provinces of Shensi, Honan, and Shantung; Kiangnan, Kiangsi, Hopeh, and part of

Chekiang followed in 1645; and the provinces of Szechwan and Fukien were added in 1646. Rebellious Ming troops were pushed back into the southwestern provinces of the country, and Dorgon suppressed revolts of the Mongolian tribes in Central Asia.

He took over the highly developed administrative system of his Chinese predecessors, reengaging Chinese experts and recruiting new civil servants through the proven method of selection and examination. Adam Schall von Bell, a German Jesuit missionary, served him as mathematician, director of the Imperial Board of Astronomy, and adviser on the manufacture of artillery. All these measures contributed to the generally favourable acceptance of the new dynasty, notwithstanding the forcible expropriation of land and the introduction of Manchurian customs, such as the pigtail.

Relegating Prince Jirgalang to the functions of assistant prince regent, Dorgon in 1644 began to gather more and more power in his hands, even venturing to impose humiliations on his nephew Haoge and other imperial princes who opposed him. Receiving the title of imperial father regent in 1648, he personally led the campaign against a rebellious Chinese general in Shansi. He also designed the plans for the construction of his own palaces in Jehol; here he intended to spend his remaining years as feudal overlord, but he died on Dec. 31, 1650, during a hunt at Kharahotun, near the Great Wall. He was posthumously proclaimed emperor and given the temple name of Ch'eng Tsung.

Dorgon's sudden death created confusion and disorder in the empire. Since he had left no male heirs, disturbances broke out, especially among the corps of the white banner unit that had been under his command. Internal shifts on the political scene brought his former enemies to power; they had succeeded in obtaining the promulgation of an imperial decree of March 1651 declaring that Dorgon had been a usurper. He was posthumously deprived of his princely rank, along with other honours; his relationship to the imperial house was disavowed; and a petition of two officials attempting to redeem his reputation was rejected. Only after the Ch'ien-lung emperor, in 1773, honoured Dorgon's services in establishing the new dynasty and restored his neglected grave was Dorgon finally fully rehabilitated.

(M.Gi.)

BIBLIOGRAPHY. Franz Michael, *The Origin of Manchu Rule in China* (1942, reprinted 1965), a concise, basic survey of the historical development of the beginning Manchu empire, includes information about Dorgon; Fang Chao-ying, "Dorgon," in Arthur W. Hummel (ed.), *Eminent Chinese of the Ch'ing Period, 1644-1912*, vol. 1, pp. 215-219 (1943), is a short biography.

DORIA FAMILY, also spelled D'ORIA, leading family in the political, military, and economic life of Genoa, from the 12th century onward.

Apparently of feudal origin, from Liguria and Provence, the Dorias first appeared in Genoese records early in the 12th century. Ansaldo Doria was elected consul of the commune of Genoa in 1134 and took part in several embassies and military expeditions. His son Simone served six consulships between 1175 and 1188, and one of Simone's sons, Andrea, married into Sardinia's ruling family, the Torres, launching Doria fortunes in that island. By this time the Dorias had long been leaders of the Ghibelline (imperial) political faction.

In 1270 Andrea's grandson Oberto Doria (died 1295) and Oberto Spinola, member of another great Genoese family, inaugurated a series of two-man governments headed by their families, with dictatorial powers as captains of the people. Ruling for 15 years during what has been termed the golden age of the Genoese medieval commune, Oberto Doria was a hero of the decisive Battle of Meloria

(1284) against Pisa, in which 250 members of the Doria family are said to have participated.

Members of the Doria family played an important role in the Genoese Crimean colony of Caffa and in the empire of Trebizond, south of the Black Sea. Domenico Doria, traveler and cartographer, was appointed in 1285 by the Mongols as their ambassador to Europe.

In the 14th century several other members of the Doria and Spinola families served as cocaptains of the people. After a popular revolution that led to the institution of a doge, the Dorias were excluded from government office (1339-1528) but provided many military leaders for Genoa in its perennial struggle with Venice.

In the 16th century the emergence of the greatest member of the family, Andrea Doria, opened a new period in the history of Genoa and of the Dorias, bringing them once more to the political fore. Giovanni Andrea (1539-1606), Andrea's grandnephew, was his lieutenant and heir, serving as Genoese admiral against the Turks in the War of Cyprus (1570-71). He took part victoriously in the Battle of Lepanto (1571), which ended the threat of Turkish supremacy in the eastern Mediterranean.

In the 16th and 17th centuries the Dorias continued to furnish military men, principally to Spain, while becoming the richest family in Genoa. In the period of the "aristocratic republic" (1528-1797) inaugurated by Andrea Doria, the family contributed six doges as well as many ambassadors and prelates.

Doria, Andrea (b. Nov. 30, 1466, Oneglia, Duchy of Milan [Italy]—d. Nov. 25, 1560, Genoa), Genoese statesman, condottiere (mercenary commander), and admiral who was the foremost naval leader of his time.

A member of an ancient aristocratic Genoese family, Doria was orphaned at an early age and became a soldier of fortune. He first served Pope Innocent VIII (reigned 1484-92) when Genoa had fallen prey to the quarrels of rival families. An extremely able soldier, he was successively hired by King Ferdinand I and his son Alfonso II of Naples and by various Italian princes. From 1503 to 1506 he helped his uncle Domenico quell the Corsican revolt against Genoan rule.

Deciding to try his fortunes on the seas, Doria outfitted eight galleys and patrolled the Mediterranean, fighting the Ottoman Turks and the Barbary pirates, augmenting both his reputation and his fortune. He scored a brilliant victory over the Turks at Pianosa in 1519. After the Holy Roman emperor Charles V's forces had taken Genoa (1522) and deposed the pro-French faction there, Doria entered the service of Francis I of France, who was fighting Charles V in Italy. As admiral of the French Mediterranean fleet, Doria compelled the emperor's army to raise the siege of Marseille in 1524. After the French defeat at Pavia (1525), at which Francis was taken prisoner by imperial forces, Doria served Pope Clement VII.

Doria, detail of a portrait by Sebastiano del Piombo; in the Doria Palace, Rome

Alinari—Art Resource/EB Inc

When Francis was freed (1527), Doria joined the French forces, which helped him capture Genoa from the imperial forces. But Doria soon became disillusioned both with French policies towards Genoa and with Francis' intentions towards himself, and so he transferred his services to Charles V. In September 1528 Doria and his forces drove the French out of Genoa and were triumphantly received by the city. Charles V bestowed riches and honours upon him, naming him grand admiral of the imperial fleet and prince of Meli.

As the new ruler of Genoa, Doria eliminated the factions that had plagued the city and constituted a new oligarchic form of government composed of the city's principal aristocratic families. (His reformed constitution for Genoa would last until 1797.) From 1528 until his death, Doria exercised a predominant influence in the councils of the Genoese republic. As imperial admiral he commanded several naval expeditions against the Turks, taking Coron (Koróni) and Patras (Pátrai) and aiding in the capture of Tunis (1535). Charles V found Doria an invaluable ally in his wars with Francis and used the former's services to extend his domination over the whole Italian peninsula.

Although he was 78 when peace was established between Francis and Charles in 1544, Doria still did not retire. He had made many enemies among the pro-French families in Genoa, and in 1547 the Fieschi family undertook a plot against the Doria family that achieved the murder of Doria's nephew Giannettino. (See Fieschi, Gian Luigi.) The conspirators were defeated, however, and Doria punished them with great vindictiveness. Other plots against him and his family followed, but all failed.

Age did not lessen Doria's energy, and at age 84 he sailed against the Barbary pirates. When a new war broke out between France and Spain, he fought the French, who had seized Corsica, then administered by the Genoese bank of San Giorgio. He retired to Genoa in 1555, passing command of his fleet to his grandnephew Giovanni Andrea Doria.

One of the last great condottieri, Doria had many of the faults of his profession: he was greedy, conceited, vindictive, unscrupulous, cruel, and authoritarian. Yet he was also a fearless and untiring military commander who was endowed with outstanding tactical and strategic talents. He was genuinely devoted to his native city of Genoa, whose liberty he secured from foreign powers and whose government he reorganized into an effective and stable oligarchy.

Dorian, any member of a major division of the ancient Greek people, distinguished by a well-marked dialect and by their subdivision, within all their communities, into the "tribes" (*phylai*) of Hylleis, Pamphyloi, and Dymanes. These three tribes were apparently quite separate in origin from the four tribes found among the Ionian Greeks. The Dorian people are traditionally acknowledged as the conquerors of the Peloponnese (in the period 1100-1000 BC).

In Greek tradition, the Dorians were thought to have gained their name from Doris, a small district in central Greece. According to this tradition, the sons of Heracles, the Heraclidae, were driven from their homeland in the Peloponnese by Eurystheus of Mycenae. The Heraclidae took refuge with Aegimius, the king of Doris. Several generations later, the Heraclid brothers Temenus, Aristodemus, and Cresphontes led the "Dorians" back in a successful invasion of the Peloponnese and thus recovered their heritage.

In actual fact, the origins of the Dorians are necessarily obscure, but it appears they orig-

inated in northern and northwestern Greece, i.e., Macedonia and Epirus. From there they apparently swept southward into central Greece and then into the southern Aegean area in successive migrations beginning about 1100 BC, at the end of the Bronze Age. The invading Dorians had a relatively low cultural level, and their only major technological innovation was the iron slashing sword. The Dorians swept away the last of the declining Mycenaean and Minoan civilizations of southern Greece and plunged the region into a dark age out of which the Greek city-states began to emerge almost three centuries later.

The migrating Dorians settled chiefly in the southern and eastern Peloponnese, establishing strong centres in Laconia (and its capital, Sparta), Messenia, Argolis, and the region of the Isthmus of Corinth. They also settled the southern Aegean islands of Melos, Thera, Rhodes, and Cos, along with the island of Crete. In fact, the Dorians reached as far east as the cities of Halicarnassus and Cnidus on the coast of mainland Anatolia (now southwestern Turkey). A great wave of renewed colonization beginning in the 8th century BC brought Dorian settlers to the island of Corcyra (modern Corfu), to Syracuse, Gela, and Acragas (now Agrigento) in Sicily, to Taras (now Taranto) in Italy, and to Cyrene in North Africa, as well as to scattered sites in the Crimea and along the Black Sea. Sparta, Corinth, and Argos were among the most important cities of Doric origin.

Doric was one of the major dialects of the classical Greek language, along with the Ionic-Attic, Aeolic, and Arcado-Cypriot dialect groups. But because the Ionic-Attic dialect of Athens dominated Greek culture from the 5th century BC, very little remains of ancient writings in pure Doric dialect.

The Dorian peoples had a seminal influence on the later development of Greek art. Indeed, the crowning achievements of Greek art and architecture from the 5th century BC arose from the combination of the art of the Doric peoples (with its restraint, power, and monumentality) and that of the Ionian peoples (with its grace, elegance, and ornateness). The massive and simple Doric order of architecture earned its name from its origin in the Doric-populated cities of the southern Aegean. The choral lyrics in Greek tragedy were also a Doric invention.

Politically, the Dorian centres took two different courses of development. In Corinth, Rhodes, Argos, and various other mercantile-oriented city-states, the Dorian invaders, though at first reserving political power unto themselves, eventually merged with the conquered indigenous peoples of their regions. In Sparta and the island of Crete, by contrast, the Dorians kept power to themselves and constituted themselves into a ruling military class. These militarized Dorian aristocracies deliberately "froze" an archaic form of society (and sacrificed most of their cultural and artistic promise in the process) in order to maintain dominance over a larger population of serfs.

Dorian mode, in music, first of the eight medieval church modes. *See* church mode.

Doric order, one of the orders of classical architecture, characterized by a simple and austere column and capital. *See* order.

Dorion, Sir Antoine Aimé (b. Jan. 17, 1818, Sainte-Anne-de-la-Pérade, Lower Canada [now Quebec, Can.]—d. May 31, 1891, Montreal), statesman and jurist, joint premier of the united province of Canada with George Brown in August 1858 and with John Sandfield Macdonald in 1863–64.

Dorion was called to the bar in 1842 and was made queen's counselor in 1863. He en-

Dorion, 1874

tered politics in 1854 as member from Montreal of the legislature of the united province of Canada. He became leader of the Rouges, or young Liberals, of Canada East (formerly Lower Canada, now in Quebec), working for reform. He gained a reputation for forthright expression of his opinions, especially in criticizing Conservative "deviousness." His solution to the question of representation by population for Canada East and Canada West (now in Ontario) in the provincial legislature in 1856 was to recommend federation.

In August 1858 Dorion formed a dual administration with George Brown of Canada West, but they resigned after three days. The alliance lost Dorion much support from the French Canadians, and he was defeated in Montreal but elected for Hochelaga. In 1862 he helped form the John Sandfield Macdonald–Louis Victor Sicotte government, becoming provincial secretary; and in 1863–64 he was premier with John Sandfield Macdonald.

In the 1860s Dorion came to be a strong critic of Confederation, fearing for the liberties of the French Canadians; but he accepted the Dominion of Canada when it was created in 1867. Dorion served as dominion minister of justice (1873–74) in Alexander Mackenzie's Liberal administration. He was appointed chief justice of Quebec in 1874, having acquired a great reputation in law. He was knighted in 1877.

Doris, the alleged mother country of the Dorian conquerors of the Peloponnese. It was a small district in central Greece, lying between Mounts Oeta (modern Oiti) and Parnassus and consisting of a narrow valley nowhere exceeding 4 miles (6 km) in breadth, with only four small townships. Doris had some importance because it commanded the road from Heraclea in Trachis to Amphissa, but its history is mainly made up of minor wars with its equally petty neighbours. In 457 BC the Spartans, admitting the claim of Doris to be the Dorian metropolis, sent an army to help it against the Phocians, and they sent another one to help it against the Oetaeans in 426. Except for mention of its cantonal league in 196 BC, Doris passed early out of recorded history.

Dorking, market town, Mole Valley district, county of Surrey, England, southwest of London. It is situated in the valley of the River Mole, between the escarpment of the chalk hills of the North Downs and the wooded heights of Leith Hill. Dorking is noted for the beauty of its countryside. The nature reserves of Holmwood Common and Box Hill in the North Downs belong to the National Trust (a British conservation body). Several fine mansions are in the vicinity of the town, notably Leith Hill Place and Polesden Lacey. Another mansion of the district is Deepdene, which has associations with Benjamin Disraeli, the 19th-century statesman. With excellent access to London, Dorking has developed as a residential town. Pop. (1991) 15,658.

dormancy, a state of reduced metabolic activity adopted by many organisms under con-

ditions of environmental stress or, often, as in winter, when such stressful conditions are likely to appear. *See* diapause; hibernation.

dormancy (botany): *see* afterripening.

dormer, in architecture, a vertical window that projects from a sloping roof and usually illuminates a bedroom. The term derives from the Latin *dormitorium*, "sleeping room." Dormers are set either on the face of the wall or high upon the roof, and their roofs may be gabled, hipped, flat, or with one slope. A small dormer in a roof or a spire is called a lucarne.

Simple dormers, frequently constructed in several rows, characterize the steep roofs of Teutonic countries. In the late Gothic and early Renaissance periods, more elaborate masonry dormers were designed that extended up

Dormers on Mulberry Plantation, Berkeley county, S.C., 1714

Wayne Andrews

from the wall line of the building and were richly decorated.

Similar elaborate dormers, usually with gabled roofs, characterize the Tudor work in England and Scotland and the French château from the time of Louis XII to that of Louis XIV. Dormers continued to be used throughout the 17th and 18th centuries and were especially popular in revival-style buildings of the 19th and 20th centuries.

dormouse, any of the 20 species of small rodents in the seven genera of the family Gliridae (order Rodentia). Six genera of dormice are distributed through Eurasia and northern Africa, and one, *Graphiurus*, occurs in sub-Saharan Africa. Dormice are generally squirrel-like, with large eyes, soft fur, rounded ears, and well-haired, sometimes bushy, tails. Like squir-

Edible dormouse (*Glis glis*)

Schunemann—Bavaria-Verlag

rels, they are typically arboreal and sit up to eat. Unlike most squirrels, they are nocturnal.

Dormice live in trees, bushes, and rock walls, and in nests of plant material. They eat fruit, nuts, birds' eggs, and some insects and small animals, and they sometimes damage orchard crops by eating only a small portion of each fruit. Dormice are proverbially regarded as extremely sleepy animals. Many do sleep for long periods. The edible and common dormice (*Glis glis* and *Muscardinus avellanarius*), for example, accumulate a large amount of fat in the fall and sleep much of the winter, rousing occasionally to eat food they have stored. Members of these two species may remain dormant from September or October to April. Dormice breed once, sometimes twice, yearly; the female bears two to nine young after about three or four weeks' gestation.

The edible dormouse, largest of the dormice, is gray and attains a maximum length of about 20 cm (8 inches) excluding its 15-centimetre (6-inch) tail. Also known as the fat dormouse, it was prized as food by the ancient Romans, who raised it in special enclosures (gliraria). The common dormouse, or hazel mouse, is a small dormouse 5 to 10 cm (2 to 4 inches) long without the tail. It is tawny brown with a white throat and white toes. Other species include the garden dormouse, or lerot (*Eliomys quercinus*), a gray or brown dormouse with a black stripe on each side of its face; the tree dormouse (*Dryomys nitedula*), a small, bushy-tailed, reddish brown dormouse; the Japanese dormouse (*Glirulus japonicus*), a chipmunk-like species with a dark stripe from head to tail; and a number of African dormice (*Graphiurus*), which are forest dwellers and are usually gray or brownish.

The spiny dormouse (*Platacanthomys lasiurus*) is a rodent similar to the dormouse and lives in rocky areas in southern India. Reddish brown and 13 to 21 cm (5 to 8 inches) long without the long tail, it has flattened spines mixed in with the hairs of its back. The spiny dormouse inhabits tree hollows and feeds on plants. Its nearest living relative is the Chinese pygmy dormouse, or blind mouse (*Typhlomys cinereus*), a small, mouselike, gray rodent about which little is known. The affinities of these two rodents are disputed. Some authorities place them in the family Cricetidae, others in a family of their own, Platacanthomyidae.

For the desert dormouse, a possible relative of the true dormice, see Selevin's mouse.

Dornberger, Walter Robert (b. Sept. 6, 1895, Giessen, Ger.—d. June 27, 1980, Baden-Württemberg, W.Ger.), engineer who directed construction of the German V-2 rocket during World War II.

Dornberger enlisted in the German army in 1914 and was commissioned the next year. After being captured by the French, he was released in 1919 and retained in the small army permitted Germany under the terms of the Versailles treaty. He was sent by the army in 1925 to the School of Technology in Charlottenberg; there Dornberger specialized in ballistics and earned an M.A. degree in 1930. He was assigned to the development of rocket weapons, a category not prohibited by the Versailles settlement, but had to struggle to obtain recognition for his efforts. In the summer of 1932, however, he was placed in charge of Research Station West at Kummersdorf, a few miles south of Berlin, where, with Wernher von Braun, he began to perfect the rocket engine. In May 1937 the staff was moved to Peenemünde, where the A series of rocket missiles was built; the A-4 rocket developed there later became widely known in its military form as the V-2 and was the forerunner of all postwar space vehicles.

After World War II, Dornberger, who had attained the rank of lieutenant general, spent two years in England as a prisoner, then emigrated to the United States in 1947, where he

worked as an adviser on guided missiles for the United States Air Force. In 1950 he became a consultant to the Bell Aircraft Corporation and in 1954 wrote *V-2*, his reminiscences. During his association with Bell, Dornberger participated in the Air Force-NASA project Dyna-Soar, which was eventually transmuted into the space shuttle program. Dornberger retired in 1965.

Dornbirn, town, Vorarlberg *Bundesland* (federal state), western Austria, on the Dornbirner Stream, in the Rhine River valley at the foot of the Bregenzer Forest, just south of Bregenz. First mentioned as Torrinquirron in 895, it belonged to the counts of Montfort from the late 12th century until it passed to Austria in 1380. It received town status in 1901. Notable landmarks are the Neoclassical parish church (1493) with a detached belfry and the Rotes Haus ("Red House"; 1639). The town has a regional nature museum. Dornbirn is the principal centre of the Austrian cotton textile industry; other economic activities include brewing, the manufacture of electrical machinery and generators, and the working of iron, wood, and plastic. It is the site of an annual international trade fair. Pop. (1987 est.) 38,641.

Consult the INDEX first

Dorner, Isaak August (b. June 20, 1809, Neuhausen, Württemberg [Germany]—d. July 8, 1884, Wiesbaden, Ger.). German Protestant theologian who sought to interpret Kantian and post-Kantian thought in terms of traditional Lutheran doctrine. The best known of the English translations of his many works is *History of the Development of the Doctrine of the Person of Christ*, 5 vol. (1861-63). Among the English versions of Dorner's writings that strove to mediate the liberal-conservative controversy within 19th-century German Protestantism are *History of Protestant Theology*, 2 vol. (1871), *System of Christian Doctrine*, 4 vol. (1880-82), and *System of Christian Ethics* (1887).

Dornier, Claudius, English CLAUDE DORNIER (b. May 14, 1884, Kempten, Bavaria [Germany]—d. Dec. 5, 1969, Zug, Switz.), pioneer German aircraft designer and builder.

Dornier completed his education in 1907 at Munich's technical college and three years later began working for Ferdinand, Graf von Zeppelin, in the Zeppelin airship factory at Friedrichshafen. In 1911 he designed the first all-metal plane, and Zeppelin permitted him to found a separate division of the company, the Dornier aircraft works at Friedrichshafen. Wooden and metal fighters designed by Dornier were used by Germany in World War I, after which he assumed full control of his aircraft factory.

During the 1920s he built widely used sea-planes, and in 1929 he introduced the Do X, at the time the world's largest aircraft. With a wingspan of 157 feet (48 m) and length of 130 feet (40 m), the Do X was powered by 12 engines and carried 169 passengers; in 1931 it flew from Germany to New York City. Because of its great cost, however, the Do X was abandoned. During World War II the Dornier 17, a twin-engined bomber, was a standby of the Luftwaffe. Construction of aircraft in postwar Germany was forbidden by the Allies, so Dornier established a factory in Spain. Shortly after the lifting of the Allied ban in 1955, he opened a factory near Munich to construct the Dornier 27, a light, general-purpose transport; the Dornier 31, a STOL aircraft; and the Dornier 32, a collapsible helicopter.

Dorotheus (fl. first half of the 6th century AD), jurist, one of the principal codifiers of Roman law under the emperor Justinian I.

Dorotheus helped to compile the Digest, or

Pandects (published in 533), and the second edition of the Codex Constitutionum (published in 534). With Tribonian (Tribonianus), head of the Digest's compilers, and Theophilus, he also prepared the Institutes (533) as an introduction to the Digest. Fragments of his Index (542), a commentary on the Digest, are preserved in the 9th-century law code called the Basilica. Dorotheus taught jurisprudence in the school of Roman law at Berytus, Syria (now Beirut, Lebanon), at that time probably the best law school in the eastern Roman Empire.

Dorpat (Estonia): see Tartu.

Dörpfeld, Friedrich Wilhelm (b. March 8, 1824, Wermelskirchen, Rhine Province, Prussia [Germany]—d. Oct. 27, 1893, Ronsdorf, Ger. [now Wuppertal, Ger.]), German educator who adapted Johann Friedrich Herbart's ideas to elementary school use and emphasized the social aspects of traditional school subjects.

After attending the Mörs teachers' seminary, Dörpfeld joined the faculty of a school in Barmen. He remained there for 30 years, also serving as principal. He was the father of Wilhelm Dörpfeld.

Though a Herbartian educator, Dörpfeld placed much greater emphasis than Herbart on the social side of education. He viewed sociology as a subject not so much to be taught for itself but rather to affect the teaching of history, geography, and other subjects. Schools, Dörpfeld believed, should be self-governing communities, free from control of both church and state in internal affairs.

Dörpfeld retired in 1880 and spent his final years writing. His most significant work was *The Connection Between Thought and Memory* (1886).

Dörpfeld, Wilhelm (b. Dec. 26, 1853, Barmen, Rhenish Prussia [now Wuppertal, Ger.]—d. April 25, 1940, Leukas, Greece), German archaeologist and authority on Greek architecture who excavated the Mycenaean palace at Tiryns (modern Tirins, Greece) and continued the excavation of the famed German archaeologist Heinrich Schliemann at Hisarlık, Tur., the site of ancient Troy.

After working with archaeologist Ernst Curtius on the excavation of ancient Olympia, he joined Schliemann at Troy (1882-90) and brought a new systematic efficiency to Schliemann's efforts. Together they numbered the successive levels of occupation I-IX. He went with Schliemann to Tiryns in 1884 and in 1885 took charge of excavation, uncovering the first fairly well-preserved Mycenaean palace of the 2nd millennium BC. In his own excavation of Troy (1893 and 1894), he concentrated on the edge of the site and uncovered Middle and Late Bronze Age ruins. He associated the destruction of Priam's Troy with level VI, though later study indicated it more likely was level VIIa. He prepared detailed architectural plans of level VI and in *Troja und Ilium*, 2 vol. (1902; "Troy and Ilium"), formulated a chronology for all levels of the site. He served as secretary of the German Archaeological Institute, Athens, from 1887 to 1911. Dörpfeld suggested in *Alt-Ithaka*, 2 vol. (1927; "Ancient Ithaca"), that modern Leukas was the Ithaca of the *Odyssey*. He also published *Alt-Athen und seine Agora*, 2 vol. (1937-39; "Ancient Athens and Its Marketplace").

Dorr, Thomas Wilson (b. Nov. 5, 1805, Providence, R.I., U.S.—d. Dec. 27, 1854, Providence), American lawyer and constitutional reformer in Rhode Island who led the Dorris Rebellion of 1842.

As a member of the state legislature (from 1834), he failed in his reform efforts. In 1841 he organized the People's Party, which called a

convention, adopted a new constitution, held elections, and, on May 3, 1842, installed Dorr as governor. The preexisting government did not recognize him, and Rhode Island for a time had two administrations. Minor armed clashes occurred. Tried for treason, Dorr was sentenced (1844) to life imprisonment, but he was released a year later.

Dorset, administrative, geographic, and historic county of southwestern England, bordered by the English Channel (south) and by the counties of Devon (west), Hampshire (east), and Somerset and Wiltshire (north). The administrative, geographic, and historic counties differ somewhat. The administrative county comprises six districts: the borough of Christchurch, East Dorset, North Dorset, Purbeck, West Dorset, and the borough of Weymouth and Portland. The geographic county encompasses these districts as well as the unitary authorities of Bournemouth and Poole. The historic county excludes Bournemouth, Christchurch, and part of East Dorset.

Chalk uplands cross into Dorset from adjoining Wiltshire. As the North Dorset Downs, they stretch through the county to beyond the historic town of Dorchester; as the South Dorset Downs, they form a narrow band of chalk terrain eastward to Swanage. Between these two areas of chalk is a triangular zone of lower-lying land developed on various sands and clays and forming an extension of the Hampshire basin. This area is drained in the west by the Rivers Frome and Piddle into Poole Bay and in the east by the Rivers Avon and Stour. To the north and west of the North Dorset Downs is found a somewhat similar band of mixed terrain. This northern part is largely drained into Christchurch Bay by the Stour and its tributaries.

Prehistoric peoples were active on the chalk uplands of Dorset. There are abundant monuments from the Neolithic Period, Bronze Age, and Iron Age. One monument that seems to have been occupied throughout prehistoric times is Maiden Castle just outside Dorchester, the main town in Roman times. The area subsequently became part of the West Saxon kingdom, and as Wessex it has been immortalized in the writings of Thomas Hardy. In the early 19th century the county was the scene of the Tolpuddle martyrs' historic stand for organized labour.

Apart from the urban complex of Bournemouth and Poole in the southeastern corner of the geographic county, Dorset is mainly rural. Agriculture remains the major user of land, though not the major employer of labour. On the chalk uplands, large farms concentrate on dairying and the cultivation of barley. In the mixed sand and clay terrain, farms are smaller, and agricultural enterprises are mixed. Pig and poultry production is carried on, as is some horticulture. Forestry now plays an important role, with most of the woodland owned by the Forestry Commission. Portland stone and Purbeck marble are renowned as building stone. Dorset also has one of the few remaining mines in the country for ball clay, which is important in the ceramics industry.

Tourism has played an increasing role in the economy, particularly in the coastal towns of Bournemouth, Poole, and Weymouth. Manufacturing is important in parts of Poole and Bournemouth and includes pottery and brick production, engineering, electronics, pharmaceutical products, and chemicals. Area geographic county, 1,025 square miles (2,655 square km); administrative county, 982 square miles (2,544 square km). Pop. (1998 est.) geographic county, 691,200; administrative county, 387,300.

Dorset, Edmund Beaufort, 1st Earl of: *see* Somerset, Edmund Beaufort, 1st duke of.

Dorset, Henry Grey, 3rd Marquess of: *see* Suffolk, Henry Grey, Duke of.

Dorset culture, prehistoric culture of Greenland (Greenlandic: Kalaallit Nunaat) and the Canadian eastern Arctic as far south as Newfoundland between approximately 800 BC and AD 1300. Its name comes from excavations made at Cape Dorset at Baffin Island. There are several theories about the origin of Dorset culture: that it originated in Alaska or another part of the western Arctic; that it derived from or was strongly influenced by certain archaic or woodland Indian cultures farther south; or

Stylized ivory amulet from the late Dorset culture in Newfoundland or Ungava Peninsula, Quebec

By courtesy of the Museum of the American Indian, New York City

that it was a basically Eskimo culture that developed in situ in the Canadian eastern Arctic from a culture called Pre-Dorset, with little Indian influence. Skeletal remains seem to be of the Eskimo type.

The Dorset people depended primarily on such sea mammals as the seal and walrus but also fished and hunted land mammals and birds. Small hand sleds were used because dogs and dogsleds were unknown; the bow drill, a typical Eskimo implement, was also lacking. Settlements, located on coasts, generally consisted of semisubterranean houses and large meetinghouses. Skin-covered tents were probably used during the summer. Evidence suggests that the Dorset people were seasonal nomads who traveled in small groups.

Dorset harpoon heads and foreshafts, knives, lanps, and chipped-stone implements were distinctive. Ornaments were made of bone, ivory, or wood, occasionally engraved. Small ivory or bone animal and human figures, which were sometimes naturalistic and sometimes stylized or grotesque, may have been used as amulets or as a form of hunting magic.

It is not certain when Dorset culture disappeared, but it was after the arrival of Thule migrants (*see* Thule culture) from Alaska, for there are indications of contact between the two groups. Climatic changes may have contributed to the decline of Dorset culture. The extent to which the Dorset influenced historic Canadian and Greenland cultures is questionable; some later types of tools derived from this culture, and a group of Eskimos (who survived in this area until 1903) may have been descendants of the Dorset people.

Dorsey, George A., in full GEORGE AMOS DORSEY (b. Feb. 6, 1868, Hebron, Ohio, U.S.—d. March 29, 1931, New York, N.Y.), early U.S. ethnographer of North American Indians, especially the Mandan tribe. His investigations of the Plains Indians included early population accounts of the area. He is best known for his last work, *Man's Own*

Show: Civilization (1931), as well as for his popular anthropology text, *Why We Behave Like Human Beings* (1925).

In 1894 Dorsey received from Harvard University the first Ph.D. in anthropology to be awarded in the United States. He taught at Harvard until 1896, when he joined the staff of the Field Museum of Natural History in Chicago. Dorsey also advised President Woodrow Wilson on Spanish affairs during the Paris Peace Conference of 1919.

Dorsey, James Owen (b. Oct. 31, 1848, Baltimore, Md., U.S.—d. Feb. 4, 1895, Washington, D.C.), American ethnologist known principally for his linguistic and ethnographic studies of the Siouan Indians.

Dorsey was ordained a deacon of the Protestant Episcopal Church in 1871, when he missioned to the Ponca tribe in the Dakota Territory. Adept in classical linguistics, he quickly learned the Ponca language, but illness forced him to return to Baltimore. When the Bureau of American Ethnology was established (1879), Dorsey, one of its first members, was sent to Nebraska to study the Omaha tribe. He was a diligent worker, studying, among the Siouan linguistic stock, the Osage, Kansa, and Dakota tribes. He also studied the Athabaskan, Takelman, Kusan, and Yakanan language stocks of Oregon. His works include *Omaha Sociology* (1884), *Osage Traditions* (1888), and *Siouan Sociology* (1897). He edited two works by Stephen Return Riggs, *A Dakota-English Dictionary* (1890) and *Dakota Grammar, Texts, and Ethnography* (1893), both of which have remained classics in their field.

Dorsey, Jimmy; and Dorsey, Tommy, by-names of JAMES DORSEY and THOMAS DORSEY (respectively b. Feb. 29, 1904, Shenandoah, Pa., U.S.—d. June 12, 1957, New York, N.Y.; b. Nov. 19, 1905, Shenandoah, Pa.—d. Nov. 26, 1956, Greenwich, Conn.), brothers who separately and together were leaders of large popular dance orchestras in the United States.

The sons of a music teacher, both benefited from early instruction, becoming prominent in white jazz circles. Jimmy, the first to emerge and the more active jazzman, remained a prolific technician on both his instruments, the clarinet and the alto saxophone; by 1927 he was a star soloist. Tommy, who began by doubling on trombone and trumpet, soon gave up the latter; by 1930 he was a successful freelance musician noted for the sweetness of tone in his trombone playing. In 1933 they formed an orchestra together. Both brothers enjoyed immense success as leaders of their own orchestras, drifting far from their jazz beginnings. In 1953 they amalgamated again. Some critics regarded their work as superior popular music rather than authentic jazz.

Dorsey, Thomas Andrew (b. July 1, 1899, Villa Rica, Ga., U.S.—d. Jan. 23, 1993, Chicago, Ill.), American songwriter, singer, and pianist whose many up-tempo blues arrangements of gospel hymns earned him the title of "Father of Gospel Music."

Dorsey was the son of a revivalist preacher. He was influenced in childhood by blues pianists in the Atlanta, Ga., area and worked in secular "hokum" music as a composer, arranger, pianist, and vocalist from 1910 through 1928. In 1916 he moved to Chicago, where he attended the College of Composition and Arranging. In the 1920s he toured with Ma Rainey and his own bands, often featuring the slide guitarist Tampa Red.

From 1929 on Dorsey worked exclusively within a religious setting, consciously applying blues melodies and rhythms to spiritual concerns. Dozens of his optimistic and sentimental songs became gospel standards, notably "Precious Lord, Take My Hand" (1932). He recorded extensively in the early 1930s, publishing his own sheet music and lyrics. From

1932 Dorsey was choral director of the Pilgrim Baptist Church in Chicago. He founded the National Convention of Gospel Choirs and Choruses in Chicago in 1933, serving as its president for 40 years. He stopped recording in 1934 but toured widely into the 1940s. Thereafter, though he continued writing, he concentrated on lecturing and administrative duties.

Dorsten, city, North Rhine-Westphalia *Land* (state), western Germany. It lies on the Lippe River and the Wesel-Datteln Canal. A village in Roman times, Dorsten was chartered by the archbishops of Cologne in 1251 and fortified in the 14th century. As a monastic centre it was a stronghold of the bishops. After 1802 it passed to the dukes of Arenberg who held it as a fief of Prussia after 1815. The city developed industrially with the advent of the railway in 1899 and the opening of the first coal mine in 1911. The northernmost city of the Ruhr industrial region, it was badly damaged by bombing during World War II. Surviving buildings include a Franciscan monastery (1488), the old city hall (1597; now a local museum), a boys' school (1642), and an Ursuline nunnery. The city was enlarged by nearly two-thirds in 1975 by the annexation of Wolfing, Lembeck, and other neighbouring towns. There are collieries, coal-gas works, an iron foundry, quartz works, and textile, wire, and furniture factories. Pop. (1992 est.) 78,814.

Dort, **Synod of**, assembly of the Reformed Church of the Netherlands that met at Dort (in full Dordrecht) from Nov. 13, 1618, to May 9, 1619. The synod tried to settle disputes concerning Arminianism (*q.v.*). In 1610 the Dutch followers of Jacobus Arminius presented to the States General a Remonstrance in five articles that contained their theological views; thus, Dutch Arminians were also called Remonstrants. They rejected the strict Calvinist doctrine of predestination, the doctrine that God elects or chooses those who will be saved. Those who opposed the Remonstrants were the Gomarists, the followers of Franciscus Gomarus, a Dutch theologian who upheld a rigid Calvinism and had carried on a theological controversy with Arminius.

The synod was attended by Gomarist Dutch delegates and also by delegates from Reformed churches in Germany, Switzerland, and England. Though it originally was intended that the synod would bring agreement on the doctrine of predestination among all the Reformed churches, in practice this Dutch synod was mainly concerned with problems facing the Reformed Church of the Netherlands.

The opening sessions dealt with a new Dutch translation of the Bible, a catechism, and the censorship of books. The synod then called upon representatives of the Remonstrants to express their beliefs. The Remonstrants refused to accept the rules established by the synod and eventually were expelled.

The synod then studied the theology of the Remonstrants and declared that it was contrary to Scripture. The canons of Dort were produced; they discussed in detail in five sections the errors of the Remonstrants that were rejected as well as the doctrines that were affirmed. The doctrines affirmed were that predestination is not conditional on belief; that Christ did not die for all; the total depravity of man; the irresistible grace of God; and the impossibility of falling from grace. These canons of Dort, along with the Belgic Confession and the Heidelberg Catechism, remain the theological basis of the Reformed Churches in The Netherlands and of the Christian Reformed Church in North America.

Dortmund, city, North Rhine-Westphalia *Land* (state), western Germany, with extensive port installations at the southern terminus of the Dortmund-Ems Canal. First mentioned as Throtmanni in 885, it became a free imperial

city in 1220 and later joined the Hanseatic League. Its far-ranging trade connections made it so prosperous in the 14th century that the English crown was pledged to its merchants as security for loans several times. Its prosperity declined after the Thirty Years' War,

Steeple of the Marienkirche (left) and the Reinoldikirche (right), across the square in the city centre, Dortmund, Ger.

Archiv für Kunst und Geschichte, Berlin

and when it lost its imperial rights in 1803 its population numbered only about 4,000. The development of coal mining and iron-ore mining in the 19th century and the completion of the canal (1899) stimulated rapid growth, and Dortmund is now a major transportation and industrial centre of the Ruhr.

Dortmund was largely destroyed in World War II, which led to planned reconstruction on modern lines. Four medieval churches—Propsteikirche, Reinoldikirche, Marienkirche, and the Petrikirche—have been restored, and the city retains four moated castles and the ruins of Saxon and Carolingian fortresses. Notable examples of modern architecture are the synagogue (1956) and the Westfalenhalle (Westfalen Hall; 1952), one of Europe's largest halls, which is used for conventions, exhibitions, and sporting events. Dortmund has many educational institutions, including the Max Planck Institute for Industrial Physiology and for the Physiology of Nutrition; the Institute for Spectrochemistry and Spectroanalysis; Münster University's Social Research Institute; and schools for social studies, journalistic research, mountaineering, mining, teachers' training, and adult education as well as several museums. The Museum of Art and Culture houses the "Dortmund treasure," a cache of more than 400 gold coins. The University of Dortmund was founded in 1966.

Steel, coal, and beer are the city's principal products. Dortmund also has a large wholesale fruit and vegetable market, and its bridge-building firms operate worldwide. Pop. (1992 est.) 601,007.

Dortmund-Ems Canal, German DORTMUND-EMS-KANAL, important commercial canal in western Germany linking the Ruhr industrial area with the North Sea near Emden. It extends from Dortmund (south) to the junction with the Rhein-Herne Canal; floating docks and locks are there. Just north, it crosses the Lippe-Seitenkanal (Lippe Lateral Canal). These connections provide links between the Rhine River and the North Sea entirely within German territory. It then runs northeast and north through the canalized bed of the Ems River. Chief imports passing southward are iron ore, grain, and sugar; products sent downstream (northward) include coal, coke, stone, and gravel. The canal was opened in 1899 and is about 167 miles (269 km) long.

Dörtöyl, town, southern Turkey, at the head of the Gulf of Iskenderun. The town's impor-

tance lies in its function as a terminal where Mediterranean tankers can be loaded with oil transported from the petroleum fields of western Asia. A pipeline, 40 inches (100 cm) in diameter and about 600 miles (1,000 km) in length, carries oil to the seaport from the Kirkük oil fields of Iraq. When the pipeline opened in the spring of 1977, it carried 200,000 barrels of crude oil per day. Early in 1978 it was shut down because of a Turkish-Iraqi disagreement over payments for the oil, and, though it was later reopened, it still operated well below capacity. Some 300 miles (500 km) of pipeline also connect the port with the petroleum fields of Batman in southeastern Turkey, east of Diyarbakır. In the Dörtöyl hinterland are forests, cotton fields, and citrus orchards. Pop. (1990 prelim.) 48,030.

Dorval, city, Montréal region, southern Quebec province, Canada, on Île de Montréal (Montreal Island). It is a southwestern suburb of Montreal city facing Lac Saint-Louis, an extension of the St. Lawrence River. Off-shore to the south is Île Dorval, a summer resort. Dorval International Airport, replacing an earlier one at Saint-Hubert, has itself been superseded by Mirabel International Airport. The area was settled by the Sulpicians, a society of French priests who built a fort and mission on the site about 1670. The community was named for Jean Baptiste Bouchard (called Dorval), a French landowner. Inc. town, 1903; city, 1956. Pop. (1991) 17,249.

dory, also called JOHN DORY, any of several marine fishes of the family Zeidae (order Zeiformes), found worldwide in moderately deep waters. The members of the family are large-mouthed fish, deep-bodied but thin from side to side.

The John Dory (*Zeus faber*), a food fish of the Atlantic and Mediterranean, is one of the better-known species. It ranges from the shore to waters about 200 m (650 feet) deep and

John Dory (*Zeus faber*)

Painting by Karen Allan

reaches a maximum length of about 90 cm (3 feet). Grayish, with a distinctive, yellow-ringed black spot on each side, it has long pelvic fins, long, filamentous dorsal-fin spines, and rows of spines on the belly and at the bases of the dorsal and anal fins. A similar species, *Z. japonicus*, is found in the Pacific.

dory, small boat with pointed ends and high, flaring sides. A dory may be up to 22 feet (7 m) long and commonly has a narrow, V-shaped stern and a narrow, flat bottom. It is a seaworthy boat that can be rowed, engine-driven, or sailed; it is used extensively by New England fishermen.

The dory skiff is shorter and has lower sides and a square stern, but otherwise it resembles the dory.

Dos Hermanas, town, Seville province, in the autonomous community (region) of Andalusia, southern Spain. It lies southeast of Seville city between the Guadaira and Guadalquivir rivers. The town was founded by Ferdinand III of Castile at the time of his conquest of Seville (1248) and named Dos Hermanas

("two sisters") for the sisters of his lieutenant, Gonzalo Nazareno. Olives are the main agricultural product of the region, which also has a hemp industry and limestone quarries. Pop. (1998 est.) 92,500.

Dos Passos, John, in full JOHN RODERIGO DOS PASSOS (b. Jan. 14, 1896, Chicago, Ill., U.S.—d. Sept. 28, 1970, Baltimore, Md.), American writer, one of the major novelists of the post-World War I "lost generation," whose reputation as a social historian and as a radical critic of the quality of American life rests primarily on his trilogy *U.S.A.*

Dos Passos
By courtesy of the National Archives, Washington, D.C.

The son of a wealthy lawyer of Portuguese descent, Dos Passos graduated from Harvard University (1916) and volunteered as an ambulance driver in World War I. His early works were basically portraits of the artist recoiling from the shock of his encounter with a brutal world. Among these was the bitter antiwar novel *Three Soldiers* (1921).

Extensive travel in Spain and other countries while working as a newspaper correspondent in the postwar years enlarged his sense of history, sharpened his social perception, and confirmed his radical sympathies. Gradually, his early subjectivism was subordinated to a larger and tougher objective realism. His novel *Manhattan Transfer* (1925) is a rapid-transit rider's view of the metropolis. The narrative shuttles back and forth between the lives of more than a dozen characters in nervous, jerky, impressionistic flashes.

The execution of the Anarchists Nicola Sacco and Bartolomeo Vanzetti in 1927 profoundly affected Dos Passos, who had participated in the losing battle to win their pardon. The crisis crystallized his image of the United States as "two nations"—one of the rich and privileged and one of the poor and powerless. *U.S.A.* is the portrait of these two nations. It consists of *The 42nd Parallel* (1930), covering the period from 1900 up to the war; *1919* (1932), dealing with the war and the critical year of the Treaty of Versailles; and *The Big Money* (1936), which races headlong through the boom of the '20s to the bust of the '30s. Dos Passos reinforces the histories of his fictional characters with a sense of real history conveyed by the interpolated devices of "news-reels," artfully selected montages of actual newspaper headlines and popular songs of the day. He also interpolates biographies of such representative members of the establishment as the automobile maker Henry Ford, the inventor Thomas Edison, President Woodrow Wilson, and the financier J.P. Morgan. He further presents members of that "other nation" such as the Socialist Eugene V. Debs, the economist Thorstein Veblen, the labour organizer Joe Hill, and the Unknown Soldier of World War I. Yet another dimension is provided by his "camera-eye" technique: brief, poetic, personal reminiscences.

U.S.A. was followed by a less ambitious trilogy, *District of Columbia* (*Adventures of a*

Young Man, 1939; *Number One*, 1943; *The Grand Design*, 1949), which chronicles Dos Passos' further disillusion with the labour movement, radical politics, and New Deal liberalism. The decline of his creative energy and the increasing political conservatism evident in these works became even more pronounced in subsequent works. At his death at 74, his books scarcely received critical attention.

Dos Pilas, ancient Mayan capital, west-central Guatemala, situated near the Salinas River, about 5 miles (8 km) east of the border with Mexico. Dos Pilas was the centre of a Mayan kingdom that at the height of its hegemony covered an area of some 1,500 square miles (3,885 square km).

Archaeologists working at the Dos Pilas site in 1991 discovered the tomb of a king—as yet known only as Ruler 2 (reigned c. 698–725)—who, together with his two successors, is believed by some archaeologists to have been a significant figure in the decline of Mayan civilization. Excavations at Dos Pilas and nearby sites have revealed a significant number of what appear to be ramparts and moats unconnected to ceremonial and agricultural activities and seemingly much more labour-intensive than the earlier ceremonial structures. From this evidence some scholars have concluded that intense and relentless warfare, whether caused by or resulting in ecological collapse, may have led to the rather sudden collapse of the Mayan culture around AD 900.

Dōshō (b. 629, Kawachi province, Japan—d. 700, Japan), Japanese priest who helped introduce Buddhism into his country.

Dōshō served as a temple priest at Gangō Temple, one of the great temples at Nara, until he left for China about 653. There he studied for eight years under the Buddhist monk Hsüan-tsang (Pinyin: Xuanzang), the founder of the Wei-shih (Ideation Only, or Consciousness Only) school, which was derived from the Indian Yogācāra (also called Vijñānavāda) philosophy and stressed the idea that the world is but a representation of the mind. Dōshō returned to Japan and introduced the doctrines of the Wei-shih school. It is generally believed he founded the school known as Hossō (Chinese: Fa-hsiang), which continues the Wei-shih philosophy.

Dōshō established a centre on the grounds of the Gangō Temple where he instructed his disciples, and for 10 years he traveled around Japan to preach his doctrines. At his death, according to his wishes, his body was cremated, and he is the first person known to have been cremated in Japan.

Dōshun (Japanese scholar): see Hayashi Razan.

dosimeter, instrument that measures exposure to ionizing radiation over a given period. There are three types of dosimeters worn by persons who work with or near sources of radiation. The film badge is the most popular and inexpensive. In it, photographic or dental X-ray film, wrapped in light-tight paper, is mounted in plastic. Badges are checked periodically, and the degree of exposure of the film indicates the cumulative amount of radiation to which the wearer has been exposed. Thermoluminescent dosimeters are nonmetallic crystalline solids that trap electrons when exposed to ionizing radiation and can be mounted and calibrated to give a reading of radiation level. The ion-chamber dosimeter, like the thermoluminescent one, is reusable, but it is self-reading for immediate determination of exposure.

Dositheos, Latin DOSITHEUS (b. May 31, 1641, Aráchova, Greece—d. Feb. 8, 1707, Constantinople), patriarch of Jerusalem, an important church politician and theologian of the Greek church who staunchly supported

Eastern orthodoxy over Roman Catholicism. Ordained deacon in 1652, he became archdeacon of Jerusalem in 1661. He subsequently was made archbishop of Caesarea Palestinae (now Horbat Qesari, Israel) in 1666 and patriarch of Jerusalem in 1669.

Through correspondence and extensive journeys Dositheos became involved in the state of the Eastern church in the Balkans, Georgia, and Ukraine. To prevent Protestantism from influencing the Greek church, in 1672 he convoked the Synod of Jerusalem, which is considered to be the most important Orthodox Eastern church council in modern times. The synod supported Dositheos by condemning the doctrines, which Patriarch Cyril Lucaris of Constantinople had set forth in his *Confession of Faith* (1629). Rejecting unconditional predestination and justification by faith alone, Dositheos' synod was the culmination of a controversy started by Cyril's plan to reform the Orthodox church on Calvinistic lines.

His relations with the Russian tsar Peter I the Great (to whom he wrote many letters) were strained because of Peter's church reforms, particularly the abolition of the patriarchate of Moscow and subjection of the Orthodox Church of Russia to the state. Dositheos failed to make Peter intercede for the Eastern churches in the peace treaty with Turkey in 1702.

Dositheos' extensive writings are largely compilations from the Greek Fathers. They were directed against the Roman Catholic church and the Eastern Catholics—i.e., those Eastern churches that joined with Rome. His *History of the Patriarchate of Jerusalem*, 12 volumes, was posthumously published in 1715.

Consult the INDEX first

Dosso, town, southwestern Niger, situated about 80 miles (130 km) southeast of Niger's capital, Niamey. Dosso is the traditional headquarters of the Zerma people, who are sedentary farmers. The town is connected by road to Niamey in the west and Tahoua in the northeast. There is also an airfield at Dosso. The economy of the surrounding region is chiefly based on multicrop subsistence farming and sedentary livestock breeding. Pop. (1988 prelim.) 27,092.

Dosso Dossi, original name GIOVANNI LUTERO, or LUTERI (b. 1479–90, Mantua?, March of Mantua [Italy]—d. 1542, Ferrara, Duchy of Ferrara [Italy]), late Italian Renaissance painter, the leader of the Ferrarese school in the 16th century. He is first recorded in 1512, in Mantua, but by then he must have been in Venice and absorbed the art of Giorgione, whose style dominates Dosso's "Nymph and Satyr." He may also

"The Sorceress Circe," oil painting by Dosso Dossi, c. 1530; in the Borghese Gallery, Rome
SCALA—Art Resource

have seen some of the early works of Titian. His style was founded on the romantic approach to landscape, which reached its highest expression in Giorgione's "Tempest," but Dosso also added something of Titian's richness and a personal quality of fantasy, which reflects his knowledge of the works of the Ferrarese painters Cosmè Tura, Francesco del Cossa, and Ercole de' Roberti. He settled in Florence in 1517 and must have come once more under the influence of Titian, whose early mythologies were painted for Dosso's own patron Alfonso I of Ferrara. There is no evidence that Dosso ever went to Rome, but he was certainly acquainted with Raphael's work by 1520, and the tension of Raphael's later style was the final influence on Dosso. In his later works there is an unearthly light falling on melancholy figures arranged in a romantic dreamland. Dosso was the friend of the great Ferrarese poet Ariosto, who celebrated him in *Orlando Furioso* as one of the nine greatest living painters; and Dosso's most famous work, "The Sorceress Circe" (c. 1530; Borghese Gallery, Rome), has been seen as almost an illustration to Ariosto.

Dōst Moḥammad Khān (b. 1793, Afghanistan—d. June 9, 1863, Herāt), ruler of Afghanistan (1826–63) and founder of the Bārāzkay dynasty, who maintained Afghan independence during a time when the nation was a focus of political struggles between Great Britain and Russia.

Dōst Moḥammad was one of a number of sons of Pāyenda Khān, head of the Bārāzkay clan. In 1816 the clan rose in rebellion against the Afghan ruler Maḥmūd Shāh, who had put to death his prime minister, a member of the clan. Following eight years of civil war, the clan claimed victory. Dōst Moḥammad emerged as its most powerful member, and he ascended the throne in 1826.

With Great Britain and Russia manoeuvring for influence in Afghanistan, Dōst Moḥammad was forced to balance his nation between the two great powers. He also sought to recover territory lost from the central government's control during the civil war. The British, feeling that Dōst Moḥammad was either hostile to them or unable to resist Russian penetration, moved to take a direct role in Afghan affairs. First they negotiated unsatisfactorily with Dōst Moḥammad, and then they gave military support to an exiled Afghan ruler, Shāh Shojā'. In 1839 they tried to use British troops to place Shojā' on the throne at the capital in Kābul; this action resulted in the First Anglo-Afghan War (1839–42). Dōst Moḥammad surrendered to British forces following the capture of his family in 1840.

The position of Shojā' and the British forces in Kābul, however, deteriorated rapidly. Shojā' was killed in a rebellion, and British troops were massacred as they attempted to retreat from the city. After the British departed in 1843, Dōst Moḥammad was restored to the throne. He then tried with some success to regain control of outlying sections of the country. He also reached an accommodation with the British, signing treaties of friendship in 1855 and 1857. In June 1863 his forces, under the command of his son-in-law, captured the city of Herāt, and Dōst Moḥammad died there a few days later.

Dostoyevsky, Fyodor (Mikhailovich), Dostoyevsky also spelled **DOSTOEVSKY** (b. Nov. 11 [Oct. 30, old style], 1811, Moscow—d. Feb. 9 [Jan. 28, O.S.], 1881, St. Petersburg, Russia), Russian novelist, journalist, and short story writer whose psychological penetration into the darkest recesses of the human heart, together with his unsurpassed moments of illumination, have had a profound and universal influence on the 20th-century novel.

A brief account of the life and works of Fyodor Dostoyevsky follows; for a full biography, see **MACROPAEDIA**: Dostoyevsky.

Dostoyevsky was graduated as a military engineer, but he resigned his commission to devote himself to writing. *Poor Folk* (1846) was followed by other novels and stories of St. Petersburg life. In 1849, for his participation in a radical intellectual discussion group, Dostoyevsky was sentenced to death. The sentence was commuted to imprisonment in Siberia, and *The House of the Dead* (1861–62) is a fictionalized account of these experiences. Released in 1854, he married (1857), travelled in Europe, and, with his brother, founded a magazine, *Epokha*, in which *Notes from the Underground* (1864) appeared. *Crime and Punishment*, the first of his major novels, was published in 1866. In the next year he entered into his happy second marriage to Anna Snitkina. Other novels followed, including *The Idiot* (1868–69) and *The Possessed* (1869–72). By the time he published his last work, *The Brothers Karamazov* (1879–80), often considered his masterpiece, he was recognized in his own country as one of its greatest writers.

dōtaku, thin, elongated bell-shaped bronze forms, evidence of a short-lived bronze culture, localized in the centre of Japan, from the middle Yayoi period (c. 250 BC—c. AD 250) into the Tumulus period (c. AD 250—c. 500). *Dōtaku* are sometimes decorated with domestic and hunting scenes delineated in thread relief in a geometric, linear style; others may be decorated with a lattice or lacework pattern. They range in height from 5 inches (13 centimetres) to 53 inches (135 centimetres). Some of the *dōtaku*, or bronze bells, may have been used as percussion instruments, but it is more likely that they were nonfunctional emblems used by clan chieftains who ruled over the agricultural communities.

Dothan, city, Houston and Dale counties, seat (1903) of Houston county, southeastern Alabama, U.S. Originally settled as Poplar Head in 1858, the name was changed to Dothen and officially renamed Dothan (for a biblical location) in 1911. It is primarily a farm-trade centre of the wire grass region, with small diversified industries, and is the site of the National Peanut Festival (October). George C. Wallace State Community College is located there. Inc. 1885. Pop. (1990) city, 53,589; Dothan MSA, 130,964.

dotterel, any of several species of birds of the plover family, Charadriidae (order Charadriiformes), especially the Eurasian dotterel (*Eudromias morinellus*). The Eurasian dotterel is mottled brown above, with a broad, white eye stripe and a narrow, white band separating its breast, which is gray, from its russet-coloured belly. It is about 20 centimetres (8 inches) long. It nests in tundra and in mountains

Eurasian dotterel (*Eudromias morinellus*)
John Markham

across Eurasia to western Alaska and as far south as Britain and the Balkans, migrating to northern Africa and the Middle East. The male undertakes most of the nesting duties.

Several plovers of the genus *Charadrius* are called dotterels in Australia, as is *C.* (sometimes *Pluviorhynchus*) *obscurus* in New Zealand. Two dotterels, the tawny-throated (*Oreopholus ruficollis*) and the rufous-chested

(*Zonibyx modestus*), are found in southern South America.

Peltohyas australis is a courser (family Glareolidae) sometimes called the Australian, or inland, dotterel.

Dottore (Italian: Doctor), also called **GRATIANO**, stock character of the Italian theatrical form known as the commedia dell'arte, who was a loquacious caricature of pedantic learning. The Dottore's professional affiliation was imprecise. He was at times a legal scholar, ready with advice for any occasion, whose bungled and inept courtroom arguments were

"Biancolelli as Dottore," oil painting by unknown artist, 17th century; in the Museo Teatrale alla Scala, Milan

By courtesy of the Museo Teatrale alla Scala, Milan, photograph, Foto Marzari

the basis for comic dialogues; at other times he was a physician armed with a huge syringe and a roster of preposterous cures for any ailment; he also could be a rhetorician or grammarian. At times the Dottore wore a half mask; at other times he supplemented his own features with cheek padding and a large false nose. His dress was a short black cloak, doctor headdress (a soft, round velvet cap worn by doctors of secular faculties), and a white neck ruff. When he appeared as a physician, he wore a large turned-up hat and was called Dottore Balanzone Lombardi, after two famous 16th-century actors of this part.

Dottore's contribution to the action of the play consisted of a kind of ineffectual wandering about while talking continuously. His long-winded disquisitions, scholarly puns, and malapropisms were spoken in a jargon of Latin jumbled with local dialect.

dou (Chinese vessel): see **tau**.

Dou, Gerrit, Gerrit also spelled **GERARD** (b. April 7, 1613, Leiden, Neth.—d. Feb. 9, 1675, Leiden), Dutch Baroque painter, leading artist of the school of Leiden, especially known for his domestic genre paintings and portraits.

He was first trained by his father, a glazier and glass engraver. From 1628 to 1631 he studied with Rembrandt, adopting the master's choice of subject matter and his use of impasto, careful draftsmanship, and dramatic treatment of light and shadow; e.g., "Rembrandt's Mother" (c. 1630; Rijksmuseum, Amsterdam). After Rembrandt left Leiden in 1631, his influence on Dou gradually weakened. Dou continued to paint on wood in a small scale, often enclosing his works in spe-

cially made cases, which he decorated. The portraits of his Rembrandtesque phase gave way to a predominance of domestic genre subjects, rich in accessory details. His colours

Douai, self-portrait, oil on panel; in the Rijksmuseum, Amsterdam

By courtesy of the Rijksmuseum, Amsterdam

became cooler and his technique more highly refined. The enamel-smooth surfaces of his works are equaled by only a few contemporary painters of still life in the 17th-century Netherlands. Still life itself plays an important role in Douai's work: for example, his kitchen scenes are often crowded with vegetables, poultry, and utensils—as in "The Young Mother" (1658; Mauritshuis, The Hague). His most characteristic device is the painted "frame within the frame," or pictures where the viewer looks through a grayish stone window into a domestic interior—e.g., "A Poulterer's Shop" (National Gallery, London). After 1650 he painted many nocturnal scenes lit by candlelight—e.g., "Night-School" (c. 1660; Rijksmuseum). Douai's jewellike effects and his laboriously perfected style often became, in the hands of his numerous followers, an empty and tedious accomplishment.

A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume

Douai, also spelled DOUAY, town, northern France, in the Nord *département*, Nord-Pas-de-Calais *région*. It is situated in flat country on the Scarpe River, 24 miles (39 km) south of Lille and 13 miles southwest of the Belgian border. It is the coal-mining centre of northern France and has important chemical and engineering works. Other industries include mining, printing, and the manufacture of railway equipment and automobiles. The original university, founded in 1562, was transferred to Lille in 1887, but Douai retains the aspect of a university town because of its numerous educational establishments. The magnificent Gothic belfry, built in 1380, is 130 feet (40 m) high and has a carillon of 49 bells, installed in 1954 to replace the one destroyed by the Germans during World War I. The church of Notre-Dame was badly damaged in 1944, but its 13th-century nave has been restored. The museum of the Carthusian monastery La Chartreuse (16th–18th century) has a fine collection of 16th-century paintings.

During the Middle Ages, Douai was ruled

successively by the counts of Flanders and the dukes of Burgundy, Austria, and then Spain. In the 16th and 17th centuries it was the centre of exiled English Roman Catholics. In 1667 Louis XIV captured the town, and it was ceded to France the following year by the Treaty of Aix-la-Chapelle. The town was almost completely destroyed during the sieges of 1710 and 1712, was partly burned in 1918, and suffered greatly during World War II. Pop. (1990) 44,195.

Douai, Merlin de: *see* Merlin, Philippe-Antoine, Comte.

Douai-Reims Bible, also called REIMS-DOUAI BIBLE, also spelled RHEIMS-DOUAY, English translation of the Latin Vulgate Bible produced by Roman Catholic scholars in exile from England at the English College in Douai (then in the Spanish Netherlands but now part of France). The New Testament translation was published in 1582 at Rheims, where the English College had temporarily relocated in 1578. The Old Testament was translated shortly afterward but was not published until 1609–10, in Douai.

A group of former Oxford men, among them William Cardinal Allen, Gregory Martin (the chief translator), and Thomas Worthington, who provided the Old Testament annotations, was instrumental in its production. They undertook the work—initiated by Allen—in order to provide English-speaking Roman Catholics with an authoritative Roman Catholic version of the Bible, as an alternative to the several Protestant translations then in existence. Roman Catholic practice theretofore had effectively restricted personal use of the Bible, in the Latin Vulgate, to the clergy. The version contained many polemic notes protesting Protestant heresies. Bishop Richard Challoner issued a series of revisions (1749–72) intended to make the translation more easily understandable, and subsequent editions were based upon this revision well into the 20th century.

Douala (people): *see* Duala.

Douala, chief port of Cameroon. It is situated on the southeastern shore of the Wouri River estuary, on the Atlantic coast about 130 miles (210 km) west of Yaoundé. The Wouri Bridge, 5,900 feet (1,800 m) long, joins Douala to the banana port of Bonabéri and carries both road and rail traffic to western Cameroon. The city is connected by road to all major towns in Cameroon, has rail links to Kumba, Nkongsamba, Yaoundé, and Ngaoundéré, and is served by an international airport.

Douala served as the capital of the German Kamerun protectorate from 1901 to 1916. It again served as the capital of Cameroon in 1940–46.

With its mixture of traditional, colonial, and modern architecture, Douala has grown rapidly since World War II and is the most populous city in the republic. Western-style residential areas alternate with neighbourhoods inhabited by unskilled migrants from rural Cameroon and other African countries.

One of the major industrial centres of central Africa, Douala houses breweries, textile factories, and palm-oil, soap, and food-processing plants. It also produces building materials, metalwork, plastics, glass, paper, bicycles, and timber products. Other activities include boat and ship repairing, railway engineering, and radio assembly. Offshore reserves of natural gas had not been exploited by the mid-1990s.

Douala's deepwater port handles most of the country's overseas trade. It has special installations for handling timber products, bananas, gasoline, and bauxite, as well as fishing facilities.

Douala houses a branch (economics) of the University of Yaoundé; a variety of commercial, agricultural, and industrial schools; and research institutes for health, forestry, textile,

oilseed derivatives, and meteorology. A museum and a handicraft centre encourage the production and preservation of Cameroonian art. Pop. (1987) 810,490.

Douarnenez, town, Finistère *département*, Bretagne *région*, western France. It lies at the mouth of Pouldavid Estuary on Douarnenez Bay of the Atlantic Ocean, northwest of the city of Quimper.

Douarnenez is associated in Breton folklore with the legendary city of Ys, which was believed to lie beneath the waters of the bay, and also with the medieval story of Tristan, lover of Iseult, for whom the island astride the estuary is named. Tristan Island was formerly named Saint-Tutuarn Island for the priory founded there in 1118. The Church of Ploaré

The bay and town of Douarnenez, France

Club Inc

in Douarnenez has a Gothic steeple (1548–86), and the chapels of Saint-Michel, Sainte-Hélène, and Sainte-Croix date from the 16th and the 17th century. Douarnenez is a fishing port with fish-processing, net-making, and boatbuilding industries. Pop. (1990) 16,701.

double-aspect theory (philosophy): *see* identity theory.

double bass, also called CONTRABASS, STRING BASS, BASS, BASS VIOL, BASS FIDDLE, or BULL FIDDLE, French CONTREBASSE, German KONTRABASS, stringed musical instrument, the lowest-pitched member of the violin family, sounding an octave lower than the cello. It has two basic designs—one shaped like a viol (or viola da gamba) and the other like a violin—but there are other designs, such as that of a guitar. It varies considerably in size, the largest normally being not taller than 6 feet (1.8 m) overall. The body itself, without the neck, may be up to 4.5 feet (1.4 m) for a full-size instrument, about 3.8 feet (1.15 m) for a three-quarter size, and only slightly larger than

Double bass, viol-shaped, side and front views

EB Inc

a cello for the small chamber bass, or *bassetto*. A double bass is usually strung with four heavy strings pitched E₁-A₁-D-G; a fifth string is occasionally added—in jazz band basses, at the top of the register to allow high notes to be played more easily; in symphony orchestra basses, below the E string, tuned to C. Many basses, rather than having a fifth string, lower the compass by an extension to the E string that runs along the scroll at the end of the neck. The string is either provided with keys that sound Eb, D, Db, and C or clamped to sound E when the lower notes are not needed.

Two styles of bass bow are currently used: the short and narrow French bow (like a violin bow), held palm downward, and the broader German bow (like a viol bow), held palm upward. The double bass is also played pizzicato (by plucking with the fingers)—occasionally in symphonic orchestras and almost always in jazz and dance bands.

Forms of the double bass date from the late 15th or early 16th century and were in common use by the 18th. Ludwig van Beethoven and later composers gave the bass increased importance in the symphony orchestra. Beethoven's friend Domenico Dragonetti and the conductor Serge Koussevitzky, both skilled bassists, composed concertos for the instrument.

In jazz ensembles the bass forms part of the rhythm section and is also used as a melody instrument.

double coconut (palm): *see* coco de mer.

double jeopardy, in law, protection against the use by the state of certain multiple forms of prosecution.

In general (in countries observing the rule of double jeopardy), a person cannot be convicted twice for the same crime based on the same conduct. If a person robs a bank, he cannot twice be convicted of robbery for the same offense. Nor can he be convicted of two different crimes based upon the same conduct unless the two crimes are defined so as to prohibit conduct of significantly different kinds. Thus, a man cannot be convicted of both murder and manslaughter for the same killing, but he can be convicted of both murder and robbery if the murder arose out of the robbery. The defense of double jeopardy also prevents the state from retrying a person for the same crime after he has been acquitted. Nor can the state voluntarily dismiss a case after trial has begun in order to start over. Acquittal in one state or nation does not, however, always bar trial in another.

double refraction, also called **BIREFRINGENCE**, an optical property in which a single ray of unpolarized light entering an anisotropic medium is split into two rays, each traveling in a different direction. One ray (called the extraordinary ray) is bent, or refracted, at an angle as it travels through the medium; the other ray (called the ordinary ray) passes through the medium unchanged.

Double refraction through a calcite crystal

Double refraction can be observed by comparing two materials, glass and calcite. If a pencil mark is drawn upon a sheet of paper and then covered with a piece of glass, only one image will be seen; but if the same paper is covered with a piece of calcite, and the crystal is oriented in a specific direction, then two marks will become visible.

The Figure shows the phenomenon of double refraction through a calcite crystal. An incident ray is seen to split into the ordinary ray *CO* and the extraordinary ray *CE* upon entering the crystal face at *C*. If the incident ray enters the crystal along the direction of its optic axis, however, the light ray will not become divided.

In double refraction, the ordinary ray and the extraordinary ray are polarized in planes vibrating at right angles to each other. Furthermore, the refractive index (a number that determines the angle of bending specific for each medium) of the ordinary ray is observed to be constant in all directions; the refractive index of the extraordinary ray varies according to the direction taken because it has components that are both parallel and perpendicular to the crystal's optic axis. Because the speed of light waves in a medium is equal to their speed in a vacuum divided by the index of refraction for that wavelength, an extraordinary ray can move either faster or slower than an ordinary ray.

All transparent crystals except those of the cubic system, which are normally optically isotropic, exhibit the phenomenon of double refraction: in addition to calcite, some well-known examples are ice, mica, quartz, sugar, and tourmaline. Other materials may become birefringent under special circumstances. For example, solutions containing long-chain molecules exhibit double refraction when they flow; this phenomenon is called streaming birefringence. Plastic materials built up from long-chain polymer molecules may also become doubly refractive when compressed or stretched; this process is known as photoelasticity. Some isotropic materials (*e.g.*, glass) may even exhibit birefringence when placed in a magnetic or electric field or when subjected to external stress.

double star (astronomy): *see* binary star.

double sugar (biochemistry): *see* disaccharide.

double vision, also called **DIPLOPIA**, perception of two images of a single object, most commonly caused by temporary or permanent paralysis of eye muscles.

Normal binocular vision results from the brain's fusion of slightly different images from each eye. Points on the retina of each eye correspond to points on the opposite retina. When one of the extraocular muscles of one eye is paralyzed, the image of an object falls on the retinal fovea (small area at the centre of the retina that affords acute vision) at a point different from that where the same image is projected on the retinal fovea of the opposite eye, and the images do not correspond.

The particular muscle that is paralyzed determines the orientation of the double image. Objects that are near at hand are frequently seen in crossed images; that is, the image received by the left eye appears to the right of the image from the right eye. Farther objects are also doubled, but the images bear the appropriate relationship to each other. Generally, the image from the paralyzed eye is less distinct than that from the normal eye because the paralysis makes proper focusing difficult. The two images can also be distinguished by placing a coloured filter over one eye.

Double vision may be among the first symptoms of botulism and also occurs in other infections, head injuries, and nerve palsies or muscle disorders. The most common ocular muscle disease causing double vision is myasthenia gravis, in which diplopia may be the first symptom. The disease later affects other muscles of the body as well. Double vision also occurs in benign ocular myasthenia, which resembles myasthenia gravis but does not spread to other muscles.

Doubleday, Abner (b. June 26, 1819, Ballston Spa, N.Y., U.S.—d. Jan. 26, 1893, Mend-

ham, N.J.), U.S. Army officer, once thought to be the inventor of baseball.

Doubleday attended school in Auburn and Cooperstown, N.Y., and in 1838 he was appointed a cadet in the U.S. Military Academy (graduating in 1842). He was an artillery of-

Abner Doubleday

Culver Pictures

ficer in the Mexican War and fought in the Seminole War in Florida (1856-58). At Fort Sumter, S.C., he commanded the gunners that fired the first shots by the North in the American Civil War. He fought at Bull Run (second battle), Antietam, Fredericksburg, and Gettysburg. He held the temporary rank of major general of volunteers in 1862-63, received the permanent rank of colonel in 1867, and retired from the army in 1873.

In 1907 a commission appointed by Albert G. Spalding published its conclusion that Doubleday formulated the essential rules of baseball in the summer of 1839 at Cooperstown, N.Y., where he was an instructor in a military preparatory school. Hence Cooperstown was chosen as the site of the National Baseball Hall of Fame and Museum, although it was later proved that Doubleday was not in Cooperstown in 1839.

The Spalding Commission's finding that the national game was of purely American origin was discredited by subsequent inquiries confirming baseball's evident connection with the older English game variously called rounders, feeder, or base ball.

Doubleday, Frank Nelson (b. Jan. 8, 1862, Brooklyn, N.Y., U.S.—d. Jan. 30, 1934, Coconut Grove, Fla.), American publisher and founder of the book-publishing firm Doubleday & Company, Inc.

At the age of 15 Doubleday quit school to work for Charles Scribner's Sons, publishers, and he became manager of *Scribner's Magazine* when it was begun in 1886. In 1897, with Samuel S. McClure, he founded the Doubleday & McClure Company, the publishing house that later (1900) became Doubleday,

Frank Nelson Doubleday

By courtesy of Doubleday and Company, Inc.

Page & Company with Walter Hines Page as a partner. Doubleday built Country Life Press at Garden City, N.Y., in 1910 and established a chain of more than 30 book shops. In 1927

Doubleday and Page absorbed the George H. Doran Company and was known as Doubleday, Doran & Company until 1946, when it became simply Doubleday & Company, Inc.

Inspired by the initials F.N.D., one of Doubleday's authors, Rudyard Kipling, gave Doubleday the nickname by which he became widely known, "Effendi," the Turkish word meaning "Master." Other Doubleday authors included Joseph Conrad, O. Henry, Booth Tarkington, Edna Ferber, and Selma Lagerlöf. Doubleday wrote *A Plain American in England* (1910) under the pseudonym Charles T. Whitefield.

doublet, chief upper garment worn by men from the 15th to the 17th century. It was a close-fitting, waisted, padded jacket worn over a shirt. Its ancestor, the gipon, was a tunic worn under armour, and at first it came down almost to the knees. The civilian doublet at

Man and boy wearing doublets, "Ambrose Dudley, Earl of Warwick," oil painting c. 1580, artist unknown; in the collection of the Marquess of Bath, England

By courtesy of the Marquess of Bath, England

first had skirts but gradually lost them. It had no collar until 1540, allowing the shirt to be seen at the neck; the shirt was also visible through slashes or pinking in the material.

The sleeves, which at first were sometimes plain and close-fitting, became wide, padded, and slashed with complex designs. Detachable sleeves were worn after 1540. The doublet fastened down the front with buttons, hooks, or laces in the 16th century, though earlier it was hooked out of sight at the side.

The height and narrowness of the waist varied from country to country, as did the materials, which included rich fabrics such as velvet, satin, and cloth of gold. An extreme fashion, the peascod, or goose-bellied doublet, came to England from Holland in the 1570s; it was padded to a point at the waist and swelled out over the girdle. It survives in the traditional costume of Punch.

A gown or cloak might be worn over the doublet by the elderly or in cold weather. In the 16th century it could be worn partly open, requiring a stomacher or placard underneath. But in England in Elizabethan times a man was fully suited in doublet and hose. The two parts of his suiting were joined by points, ties threaded through opposing eyelets in each garment.

Doubs, département, Franche-Comté region, eastern France, on the Swiss frontier, created from the Alsatian principality of Montbéliard

(*q.v.*) and part of the historic province of Franche-Comté (*q.v.*). It has three *arrondissements*, Besançon, Montbéliard, and Pontarlier, and is in the educational division of Besançon. Doubs has an area of 2,019 sq mi (5,228 sq km). The Doubs River, which gives the *département* its name, makes a loop round Besançon (*q.v.*), its capital, while the Ognon River forms the northwestern border, which also is crossed northeast-southwest by four parallel chains of the Jura Mountains. The highest and most easterly chain contains Mont d'Or (4,790 ft [1,460 m]).

The climate is cold and rainy, with generally severe winters. Snow usually lies from six to eight months on the upper regions, which are barren or covered with vast fir forests and have good pasturelands. All varieties of cereals, as well as vegetables, fruits, and vines, are grown on the plains. Cooperative factories produce large quantities of Gruyère cheese.

The *département* is largely rural. Most of the towns are in or near the Doubs Valley, in which the major industries (watches, hardware, motor vehicles, textiles, food) are situated. The northern part of the *département* is almost entirely dominated by the automobile industry at Montbéliard, which employs specialized manpower from as far as 50 mi (80 km) away. Pontarlier, another but more traditional industrial centre (distilleries, cheese, hosiery, sawmills) in the mountain region, lies in the upper Doubs Valley. Tourism is well developed. Pop. (1982) 477,163.

Doubs River, river in eastern France. The river justifies its Latin name, Dubius, by its erratic course, rising near Mouthe in the Jura Mountains (in the Doubs *département*) at a height of 3,074 ft (937 m) and following a course 267 mi (430 km) long to flow into the Saône at Verdun-sur-le-Doubs, only 56 mi to the west. Where not canalized, the river is navigable for only a few miles above its mouth, where it flows northeastward toward the Rhine and doubles back on itself. In its upper course it is partly a torrent. It forms the Lac de Saint-Point before passing Pontarlier, and then is a waterfall (Saut du Doubs) at the Lac des Brenets, after which it flows for some 20 mi through gorges. After making a short incursion into Swiss territory, it has a hairpin bend at Saint-Ursanne before flowing westward through Saint-Hippolyte. Coursing northward, it bends sharply below Montbéliard, where it is joined by the Rhine-Rhône Canal. It flows southwestward to Besançon, capital of the Doubs *département*, looping round the centre of the city, to join the Saône after crossing Dole.

doubt, methodic (Cartesian philosophy): *see* methodic doubt.

Doudart de Lagrée, Ernest-Marc-Louis (de Gonzague) (b. March 31, 1823, Saint-Vincent-de-Mercuze, Fr.—d. March 12, 1868, T'ung-ch'uan, Yunnan Province, China), French explorer and diplomat who secured French hegemony over Cambodia.

Doudart de Lagrée entered the French Navy in 1845. In 1863 he became the first French representative to Cambodia, when he was sent from Saigon, in Vietnam, to Oudong to urge King Norodom (*q.v.*) to accept French protection. Cambodia was shared as a vassal by Siam and Vietnam, and the Siamese seemed ready to invade the country. Norodom's position was also threatened by his two half brothers, Sisowath and Si Votha (*qq.v.*). The former hesitated to make an open challenge, but the latter went into dissidence in 1860. As the French representative in Cambodia, Doudart gained Norodom's reluctant agreement to a treaty of protection in 1863, threatening to depose Norodom in the following year when the Cambodian king seemed ready to return himself to Siamese (Thai) protection. The French justified their actions in Cambodia by

claiming to have succeeded to Vietnam's role as one of Cambodia's suzerains.

Doudart became a commander in the French Navy in 1864 and was appointed French resident at Phnom Penh. In 1866 he led a geographic survey and exploration of the Mekong River into Laos and China. He died in northern Yunnan.

Dougga (Tunisia): *see* Thugga.

dough, mixture of flour and liquid with other ingredients, such as leavening agents, shortening, sugar, salt, eggs, and various flavouring materials, used to make baked products. A similar mixture, in more liquified form, is known as batter.

Doughs are thick and plastic and may be shaped, kneaded, and rolled. They are elastic, allowing much expansion during baking, the degree of elasticity depending upon the amount of elastic protein, or gluten, provided by the flour employed. Doughs are used to make breads and pastries. Sweet doughs, used for such products as coffee cakes and Danish pastries, are richer than bread doughs; they contain larger amounts of shortening, milk, and sugar and various spices, nuts, and fruits.

Doughs used for flatbreads and most piecrusts are unleavened and do not expand. Puff pastes, used for patty shells and napoleons (pastry layers filled with custard or whipped cream), and authentic Danish pastries are made of alternating dough and shortening layers that are rolled until the layers are quite thin, producing flaky, tender pastry. At high altitudes, ingredient proportions may require alteration, with reduced leavening and increased liquid compensating for differences in atmospheric pressure that lower the boiling point of the liquid and cause dough to rise more rapidly.

Dougherty, Walter Hampden (American actor): *see* Hampden, Walter.

Doughty, Charles Montagu (b. Aug. 19, 1843, Theberton Hall, Leiston, Suffolk, Eng.—d. Jan. 20, 1926, Sissinghurst, Kent), British traveller, widely regarded as one of the greatest of all Western travellers in Arabia.

After attending London and Cambridge universities, he travelled widely in Europe, Egypt, the Holy Land, and Syria. He began his journey to northwestern Arabia at Damascus in 1876 and proceeded southward with pilgrims headed for Mecca as far as Madā'in Šālīh. There he studied monuments and inscriptions left by the ancient Nabataean civilization. His observations were published by Ernest Renan. On the latter part of his journey, however, which included visits to Taymā', Ḥā'il, 'Unayzah, at-Tā'if, and Jidda, he made his most important geographical, geological, and anthropological observations.

In 1888 he published *Travels in Arabia Deserta*, which won little recognition at the time, though it eventually came to be regarded as a masterpiece of travel writing. In it he was more concerned with producing a monument of what he considered to be pure English prose than with recording information. The Elizabethan style in which it is cast succeeds in conveying the feeling of his remote and lonely wandering. Doughty himself, however, attached more importance to his epic and dramatic poetry. These works include *The Dawn in Britain*, 6 vol. (1906), *The Clouds* (1912), and *Mansoul* (1920).

Douglas, municipal borough and capital, since 1869, of the Isle of Man, one of the British Isles. It lies on the island's east coast, 80 mi (130 km) northwest of Liverpool (across the Irish Sea). Low hills encircle the town, penetrated by the valley of the combined Dhoo (Manx, "dark") and Glass (Manx, "light") rivers, from which it takes its name.

Douglas grew rapidly in the 18th century as a result of the smuggling trade and by 1850 was a popular watering place. The Tynwald,

or Manx Parliament, and the House of Keys, one of its legislative branches, are situated in the Legislative Buildings, built (1894) on Prospect Hill. The Tynwald Court is composed of the two legislative branches—the House of Keys and the Legislative Council—sitting in joint session, but voting separately. The town's primary occupations are tourism, light precision engineering, brewing, and mineral water works. At the mouth of the rivers is the harbour, which can be viewed from a two-mile promenade circling it; 7 mi (11 km) southwest is a civil airport.

Of interest are the Tower of Refuge, built in 1832 on the dangerous Conister, or St. Mary's Rock, in Douglas Bay; Castle Mona (1804); and the Manx Museum. The Tourist Trophy motorcycle races and international cycle races are held each June; the Manx Grand Prix race is in September. The Manx Electric Railway connects Douglas with Ramsey and the summit of Snaefell (2,034 ft [620 m]). The Isle of Man Steam Railway connects Douglas with Port Erin. Pop. (1981) 19,944.

Douglas, suburb of Juneau (*q.v.*), Alaska, U.S.

Douglas, city, Cochise county, in Sulphur Springs Valley, southeastern Arizona, U.S. A port of entry (on the Mexican border), it is separated from Agua Prieta by International Avenue. It was founded c. 1900 as a copper-smelting centre and was named for James Douglas, president of the Phelps Dodge (mining) Corporation. Irrigation development, enabling cattle raising and farming, broadened its economy. It now serves as an import point for eastern Sonora, Mex. Immediately west is Cochise College (1964). Inc. 1905. Pop. (2000) 14,312.

Douglas, city, seat (1858) of Coffee county, south central Georgia, U.S. Founded in 1858 and named for U.S. Sen. Stephen A. Douglas of Illinois, it is the trading centre for a five-county area and is one of the state's most important tobacco markets. Forestry, livestock and poultry raising, and the manufacture of mobile homes and clothing are other economic activities. South Georgia College, established there in 1906, is the state's oldest state-supported junior college. Inc. town, 1895; city, 1897. Pop. (2000) 10,639.

Douglas, city, seat (1887) of Converse county, east central Wyoming, U.S., on the North Platte River, 52 mi (84 km) east of Casper. Founded in 1886 with the arrival of the railroad, it was first called Tent Town but was renamed to honour Stephen A. Douglas, Lincoln's political opponent. It is a trade centre

Douglas, EARLS OF, titled Scottish nobility, in branches of the Douglas family, grouped below chronologically and indicated by the symbol ●.

● **Douglas, William Douglas, 1st earl of**, also called EARL OF MAR (b. c. 1327—d. May 1384, Douglas, Lanarkshire, Scot.), Scottish lord of the Douglases, prominent in the dynastic and English wars of the 14th century.

The son of Sir Archibald Douglas (d. 1333), regent of Scotland, who was killed at the Battle of Halidon Hill, he was educated in France and returned to Scotland in 1348. He killed his kinsman and godfather, Sir William (c. 1300–53), the knight of Liddesdale, in Ettrick Forest (1353) and acquired part of Liddesdale. His marriage (1357) with Margaret, sister and heiress of Thomas, 9th earl of Mar, brought him the estates and earldom of Mar (1374), and he was created earl of Douglas in January 1358. He joined King David II in proposing a treaty (1363–64) with England, which would substitute for Robert the Stewart (afterward Robert II) an English prince as heir to the Scottish throne. David was seeking a remission of his ransom, William the return of his family's English estates. On the accession (1371) of Robert II he was nevertheless reconciled and was appointed warden of the marches.

● **Douglas, James Douglas, 2nd earl of** (b. c. 1358—d. August 1388, Otterburn, Roxburghshire, Scot.), Scottish leader in wars against the English in the late 14th century.

Son of the 1st earl, William Douglas, he married (1371 or 1373) Isabel, daughter of King Robert II. He invaded England (1388), besieged Newcastle for three days, and captured the pennon of Sir Henry Percy ("Hotspur") in single combat. Percy sought revenge in the Battle of Otterburn (August 1388), which is celebrated in English ballad as "Chevy Chase" and Scottish ballad as "Battle of Otterburn." The Scots were victorious, and Percy and his brother were captured; but James was killed. He left no legitimate male issue, but his illegitimate sons William (d. c. 1421) and Archibald (d. c. 1456) founded the families of Douglas of Drumlanrig and Douglas of Cavers.

● **Douglas, Archibald Douglas, 4th earl of**, DUC (duke) DE TOURAINE, byname TYNE-MAN (b. c. 1369—d. Aug. 17, 1424, Verneuil, Fr.), Scottish commander in the Scottish and French wars with the English in the early 15th century.

Son of the 3rd earl, Archibald the Grim, he married Margaret, daughter of the future Robert III of Scotland. As master of Douglas (1400) he defeated Sir Henry Percy ("Hotspur") and George Dunbar, earl of March near Preston, and acquired the lands that March thus forfeited. When the other lands were restored (1409) he retained the lordship of Annandale. Archibald was, with the regent, Robert, duke of Albany, suspected of compassing the Duke of Rothesay's death (March 1402) while he was in their custody at Falkland; but both were declared guiltless by Parliament.

In a raid upon England Archibald was captured by Percy at the Battle of Homildon Hill (September 1402); he fought with his captors against Henry IV at the Battle of Shrewsbury (1403) and was taken prisoner by the English king. He was allowed to visit Scotland several times after 1405, negotiating between the Scots and English for the release of the Scots king James I, who had been captured by the English (1406) while sailing to France. Archibald was finally freed in 1413.

He commanded a contingent of 10,000 Scots sent to help the French king Charles VII against the English and was made lieutenant general of the French army. Archibald received the peerage-duchy of Touraine with

remainder to his male heirs. He was killed fighting against John, duke of Bedford, at the Battle of Verneuil and was buried in Tours cathedral.

● **Douglas, William Douglas, 8th earl of** (b. c. 1425—d. Feb. 22, 1452, Stirling, Stirling, Scot.), prominent Scottish lord during the reign of James II of Scotland.

The so-called Black Douglases, of whom the 8th earl was a member, had lost their lands through accusations of treason; but the Earl recovered Galloway and Wigtown by marriage with his cousin, the heiress Margaret Douglas, the "Fair Maid of Galloway." The estate of Bothwell was granted to him by James II, with whom he at first stood in high favour.

In 1450, however, James II raided the Earl's lands during his absence on a pilgrimage to Rome; their relations seemed outwardly friendly, however, until 1452, when the King invited Douglas to Stirling Castle under a safe-conduct—in itself, however, a proof of strained relations. There James demanded the dissolution of a league into which Douglas had entered with Alexander Lindsay, the "Tiger," 4th earl of Crawford. On Douglas' refusal the King murdered him with his own hands, the courtiers helping to dispatch him.

● **Douglas, James Douglas, 9th earl of** (b. 1426—d. July 14, 1488, Lindores Abbey, Fife, Scot.), last of the first line of the earls of Douglas, caught in the internal wars of Scotland and the intrigues with the English.

He at first attempted to avenge the murder of his brother, the 8th earl; but, deserted by his allies, he was obliged to submit to King James II (August 1452). To keep the family estates together, he obtained a dispensation to marry his brother's widow, Margaret, the "Fair Maid of Galloway."

He openly accused the King of the murder of his brother (1454) and led 40,000 men against him. Meanwhile another branch of the family, known as the Red Douglases, had risen to importance and supported the King against their chief. Douglas, again deserted by his allies, fled to England; he was attainted (June 1455) and his wife divorced him. The lordship of Douglas was granted to the Earl of Angus.

Douglas, who had long intrigued with the Yorkist faction in England, was favoured by Edward IV of England, who sent him (1461) to make a treaty with John, earl of Ross and lord of the Isles, against the Scottish king, who had given asylum to the fugitive English king Henry VI. Douglas was captured while raiding southern Scotland (1484) and relegated to Lindores Abbey, Fife, where he died four years later.

Douglas, Archibald: see Douglas, Archibald Douglas, 4th earl of; Angus, Archibald Douglas, 6th earl of; Angus, Archibald Douglas, 8th earl of, Earl of Morton.

Douglas, Clifford (Hugh) (b. Jan. 20, 1879, Stockport, Cheshire, Eng.—d. Sept. 29, 1952, Dundee, Scot.), British economist and originator of the theory of Social Credit.

He began a career in engineering and management, but society's failure to utilize modern technology fully stimulated his interest in economic theories. These were expounded (1919) in *The New Age*, the socialist publication of Alfred Richard Orage, and in Douglas' first book, *Economic Democracy* (1920). His basic idea was that the remedy for the chronic deficiency of purchasing power in the economy would be the issuance of additional money to consumers, or of subsidies to producers, in order to liberate production from the price system. Douglas' ideas attracted considerable public attention in the early 1920s, but the only extensive following was in Al-

Ayres' Natural Bridge, near Douglas, Wyo.

Milt and Joan Mann from CameraMann

for a livestock, grain, poultry, and petroleum region and the home of the annual Wyoming State Fair. Nearby are the restored site of Ft. Fetterman, built in 1867 during the Sioux wars, and Ayres' Natural Bridge, a 100-ft (30-m) arch spanning La Prele Creek. A division of the Medicine Bow National Forest is across the river to the south, and the Thunder Basin National Grassland lies to the north. Inc. town, 1886. Pop. (2000) 5,288.

berta, Canada, where the Social Credit Party was founded in 1935. The party dominated the province's politics until 1971, but Douglas' principles were virtually abandoned in the late 1930s.

Douglas, David (b. 1798, Scone, Perthshire, Scot.—d. July 12, 1834, Sandwich [Hawaiian] Islands), Scottish botanist who was a traveller and botanical collector in North America and for whom the Douglas fir (*Pseudotsuga menziesii*, or *P. douglasii*) and the primrose genus *Douglasia* are named.

After serving as a gardener at the Botanical Garden at Glasgow, Douglas went to the U.S. as a botanical collector for the Royal Horticultural Society. His first trip was to the Oregon Territory in 1823; he later made several other scientific journeys, especially to the North American Far West. In 1825 he went to British Columbia and travelled inland to Hudson Bay, which he reached in 1827; he discovered many new animal and plant species along the way, including the Douglas fir. From 1830 to 1834 he explored California and the Fraser River region. He introduced some 50 new trees and shrubs and about 100 herbaceous plants into England during his career.

Douglas, Donald (Wills) (b. April 6, 1892, Brooklyn, N.Y., U.S.—d. Feb. 1, 1981, Palm Springs, Calif.), U.S. aircraft designer who founded the Douglas Aircraft Company.

Douglas assisted Jerome C. Hunsaker in building the first wind tunnel, at the Massachusetts Institute of Technology, Cambridge

Donald Douglas, 1970

By courtesy of the McDonnell Douglas Corporation

(1914–15), and was chief engineer for the Glenn L. Martin Company before organizing his own firm in 1920. His early government contracts included an order for the Douglas World Cruiser biplanes. Two of the four planes that set out on the first around-the-world flight, on April 6, 1924, completed the trip on September 28. The prototype DC-1 commercial transport (flown July 1933) and the production model DC-2 were succeeded (1935) by the larger and more powerful DC-3 (military designation C-47 [Dakota]). The four-engined DC-4 (military versions, Air Force C-54 and Navy R5D-1) and the DC-6 and DC-7 series were commercially successful.

During World War II, Douglas manufactured the A-20 (Havoc) and A-26 (Invader) light bombers and the SBD (Dauntless) dive bomber. Postwar aircraft include the DC-8, DC-9, and DC-10 jet transports and the A-4 (Skyhawk) attack bomber. In 1957 he resigned as president of Douglas Aircraft but remained as chairman of the board of directors and chief executive officer until 1967, when the company became a division of McDonnell Douglas Corporation.

Douglas, Gawin, Gawin also spelled GAVIN (b. 1475?—d. September 1522, London), Scottish poet and first British translator of the *Aeneid*. As a bishop and a member of a powerful family, he also played an important part in a troubled period in Scottish history.

Four surviving works attributed to Douglas reflect his moral earnestness and his command of difficult metrical forms. They are: a long poem, *Conscience*; two moral allegories, *The Palice of Honour* and *King Hart*; and the *Aeneid*. *The Palice of Honour* (1501), a dream allegory on the theme "where does true honour lie," extols a sterner rhetorical virtue than the young poet was to exemplify in his own subsequent career. *King Hart* (uncertainly ascribed to Douglas) describes vigorously and graphically the progress of Hart (the human soul) from a youthful enslavement to pleasure through the inevitable assaults of conscience, age, and death. Douglas' last literary work was the first direct translation of the whole *Aeneid* to be made in Britain.

After the Battle of Flodden (1513), in which James IV of Scotland was killed, creating a struggle for power between rival Scottish factions, Douglas abandoned his literary career for political activities. The marriage of the King's widow, Margaret Tudor, sister of Henry VIII, to Douglas' nephew invested the Douglas family with an almost royal dignity and aligned them with the pro-English faction in Scotland. Douglas became bishop of Dunkeld and the Queen's chief adviser and involved himself in a series of intrigues to advance her cause and the power of his family, which led ultimately to his downfall. In 1521 he was forced by political enemies to flee to England, where he remained in exile until his death in London from the plague. In his last years he found comfort in his friendship with an Italian Humanist, Polidoro Vergilio.

Though his work stands on the threshold of Renaissance Humanism, Douglas' heritage as a poet and translator is medieval. In his rendering of the *Aeneid* he shows a scholarly concern with the technique of translation and sensitivity to linguistic differences, but he is medieval in the casual way he brings his original up to date, and in the absence of "classical" diction and gravity of tone. Each book has an original prologue that is a notable piece of writing.

Douglas, George, pseudonym of GEORGE DOUGLAS BROWN (b. Jan. 26, 1869, Ochiltree, Ayrshire, Scot.—d. Aug. 28, 1902, London), Scottish novelist who was instrumental in the realistic literature movement of the early 20th century. Educated at Glasgow University and Balliol College, Oxford, he was a brilliant student who won many awards. After graduation in 1895 he travelled to London to write for metropolitan newspapers, eventually becoming a publisher's reader.

Douglas' novel *The House With the Green Shutters* (1901), one of the first literary works to forego romance or adventure, received much attention for its realistic study of contemporary Scottish life. Another novel, *Love and a Sword* (1899), was not nearly so influential. He died suddenly, at the height of his career.

Douglas, James: see Douglas, James Douglas, 2nd earl of; Douglas, James Douglas, 9th earl of; Morton, James Douglas, 4th earl of.

Douglas, James (b. Nov. 4, 1837, Quebec—d. June 25, 1918, New York City), Canadian-born U.S. mining engineer, industrialist, and philanthropist who contributed greatly to the industrial growth and welfare of the U.S. Southwest.

He attended the University of Edinburgh for two years, studying medicine and theology. He then returned to Canada, graduating in 1858 from Queen's University, Kingston, Ont., where he was later chancellor.

James Douglas, oil painting by E.W. Grier, 19th century, in a private collection

By courtesy of the Phelps Dodge Corp

With T. Sterry Hunt (1826–92), he invented the Hunt–Douglas process for extracting copper from its ores. In 1875 he became superintendent of the Chemical Copper Company, Phoenixville, Pa., where he installed the first commercial electrolytic plant for refining copper. Six years later, the metal dealers Phelps, Dodge and Company of New York employed him to examine copper mines in Arizona, leading to the acquisition of mines at Bisbee and Morenci. These mines were the beginning of the Copper Queen Consolidated Mining Company, of which Douglas became president. Later, the company acquired other mines and built the El Paso and Southwestern Railroad. Douglas encouraged radium-ore mining and presented more than three grams of radium to General Memorial Hospital, New York City, stimulating later cancer research by that institution. From 1899 to 1901 he was president of the American Institute of Mining Engineers; from 1916 until his death he was chairman of the board of directors of the Phelps Dodge Corporation.

Douglas, Sir James, byname BLACK DOUGLAS (b. c. 1286—d. Aug. 25, 1330, Spain), lord of the Douglas family and champion of Robert de Bruce (King Robert I of Scotland).

Son of Sir William Douglas (d. c. 1298), who was captured by the English and died in the Tower of London, Sir James was educated in Paris and returned home to find an Englishman, Robert de Clifford, in possession of his estates. He joined Robert de Bruce, attending his coronation at Scone (March 1306) and sharing his wanderings in the Highlands after their defeat at the Battle of Methven (June 1306). The following year they separated, Sir James returning to the south of Scotland, when he three times attacked his own castle at Douglas, finally destroying it. His assault made on Palm Sunday, March 19, 1307, is known as the "Douglas Larder." His many successful raids on the English won him the dreaded name of the "Black Douglas." Through the capture of Roxburgh Castle (1313) by the stratagem of disguising his men as black oxen, he secured Teviotdale; and at the Battle of Bannockburn (June 1314) he commanded the left wing with Walter the Steward. He invaded Yorkshire (1319) with Thomas Randolph, earl of Moray, defeating an English army assembled at Myton-upon-Swale. Shortly before peace was finally concluded, he nearly captured Edward III in a daring night attack on the English camp in Weardale (August 1327).

Before his death (1329) Bruce asked Sir James to carry his heart to the Holy Land in redemption of his unfulfilled crusading vow; Sir James set out (1330), bearing the embalmed heart in a silver casket, but he fell that year fighting against the Moors in Spain.

Douglas, Sir James (b. Aug. 15, 1803, Demerara, British Guiana—d. Aug. 2, 1877, Victoria, B.C., Can.), Canadian statesman known as "the father of British Columbia." He be-

came its first governor when it was a newly formed wilderness colony.

Douglas joined the Hudson's Bay Company in 1821 and rose to become senior member of the board, in charge of operations west of the Rocky Mountains. After the establishment of the southwestern boundary with the United States, he moved the company's headquarters from Oregon to Vancouver Island in 1849. As governor (1851–64) of Vancouver Island when gold was discovered on the Fraser River in 1858, he extended his authority to the mainland in order to preserve Britain's foothold on the Pacific in the face of an influx of settlers from the United States. His action was approved by the British government, which then created the colony of British Columbia. Douglas became its governor in 1858 after severing his connection with the Hudson's Bay Company. He was knighted in 1863 and retired in 1864.

Douglas, Keith Castellain (b. Jan. 20, 1920, Royal Tunbridge Wells, Kent, Eng.—d. June 9, 1944, Normandy, Fr.), British poet who is remembered for his irony, eloquence, and fine control in expressing the misery and waste of war, to which he was to fall victim.

Douglas' education at Oxford University was cut short by the outbreak of war. By 1941 he was serving as a tank commander in North Africa, where some of his most powerful poems were written (*Alamein to Zem-Zem*, 1946). He was moved back to Britain in 1944 to take part in the D-Day invasion; he fell in combat in Normandy on his third day there. His posthumous *Collected Poems* (1951) enhanced his reputation as a war poet, but in 1964 Ted Hughes's edition of Douglas' *Selected Poems* established him as a poet of universal significance.

Douglas, Margaret: see Lennox, Margaret Douglas, countess of.

Douglas, (George) Norman (b. Dec. 8, 1868, Thüringen, Austria—d. Feb. 9, 1952, Capri, Italy), essayist and novelist who wrote of southern Italy, where he lived for many years, latterly on the island of Capri—the setting of his most famous book, *South Wind*. All his books, whether fiction, topography, essays, or autobiography, have a charm arising from Douglas' uninhibited expression of a bohemian, aristocratic personality. His prose is considered somewhat near the perfection of the conversational style.

Douglas was born of an old Scottish landowning family, which had intermarried with German aristocrats, and he attended the *Gymnasium* at Karlsruhe, Ger., where he showed a precocious gift for both languages and natural science. He entered the British Foreign Office in 1893 but spent only about three years on diplomatic service (in Russia), after which he travelled widely in India, Italy, and North Africa.

His first notable book was *Siren Land* (1911) and his first popular success the satirical novel *South Wind* (1917). Perhaps the richest of his books is *Old Calabria* (1915) and the most self-revealing, his informal autobiography *Looking Back* (1933).

Douglas, Stephen A(rnold) (b. April 23, 1813, Brandon, Vt., U.S.—d. June 3, 1861, Chicago), U.S. politician, leader of the Democratic Party, and orator who espoused the cause of popular sovereignty in relation to the issue of slavery in the territories before the American Civil War (1861–65). He was re-elected senator from Illinois in 1858 after a series of eloquent debates with the Republican candidate, Abraham Lincoln, who defeated him in the presidential race two years later.

Douglas left New England at the age of 20 to settle in Jacksonville, Ill., where he quickly rose to a position of leadership in the Illinois Democratic Party. In 1843 he was elected to the U.S. House of Representatives: one of

Stephen Douglas, detail of a photograph by Case and Getchell, c. 1861

By courtesy of the Chicago Historical Society

its youngest members, Douglas gained early prominence as a dedicated worker and gifted speaker. Heavyset and only five feet four inches tall, he was dubbed the "Little Giant" by his contemporaries.

Douglas embraced a lifelong enthusiasm for national expansion, giving consistent support to the annexation of Texas (1845), the Mexican War (1846–48), taking a vigorous stance toward Great Britain in the Oregon boundary dispute (1846), and advocating both government land grants to promote transcontinental railroad construction and a free homestead policy for settlers.

Douglas was elected in 1846 to the U.S. Senate, in which he served until his death; there he became deeply involved in the nation's search for a solution to the slavery problem. As chairman of the Committee on Territories, he was particularly prominent in the bitter debates between North and South on the extension of slavery westward. Trying to remove the onus from Congress, he developed the theory of popular sovereignty (originally called squatter sovereignty), under which the people in a territory would themselves decide whether to permit slavery within their region's boundaries. Douglas himself was not a slaveholder, though his wife was. He was influential in the passage of the Compromise of 1850 (which tried to maintain a congressional balance between free and slave states), and the organization of the Utah and New Mexico territories under popular sovereignty was a victory for his doctrine.

The climax of Douglas' theory was reached in the Kansas-Nebraska Act (1854), which substituted local options toward slavery in the Kansas and Nebraska territories for that of congressional mandate, thus repealing the Missouri Compromise of 1820. The act's passage was a triumph for Douglas, although he was bitterly condemned and vilified by antislavery forces. A strong contender for the Democratic presidential nomination in both 1852 and 1856, he was too outspoken to be chosen by a party that was still trying to bridge the sectional gap.

The Supreme Court struck indirectly at popular sovereignty in the Dred Scott Decision (1857), which held that neither the Congress nor territorial legislatures could prohibit slavery in a territory. The following year Douglas engaged in a number of widely publicized debates with Lincoln in a close contest for the Senate seat in Illinois, and although Lincoln won the popular vote, Douglas was elected 54 to 46 by the legislature. In the debates, Douglas enunciated his famous "Freeport Doctrine," which stated that the territories could still determine the existence of slavery through unfriendly legislation and the use of police power, in spite of the Supreme Court decision. As a result, Southern opposition to Douglas intensified, and he was denied reappointment to the committee chairmanship he had previously held in the Senate.

When the "regular" (Northern) Democrats

nominated him for president in 1860, the Southern wing broke away and supported a separate ticket headed by John C. Breckinridge of Kentucky. Although Douglas received only 12 electoral votes, he was second to Lincoln in the number of popular votes polled. Douglas then urged the South to acquiesce in the results of the election. At the outbreak of the Civil War, he denounced secession as criminal and was one of the strongest advocates of maintaining the integrity of the Union at all costs. At Pres. Lincoln's request, he undertook a mission to the Border States and to the Northwest to rouse Unionist sentiments among their citizenry. Douglas' early and unexpected death was partly the result of these last exertions on behalf of the Union.

Douglas, Thomas: see Selkirk, Thomas Douglas, 5th earl of.

Douglas, William: see Angus, William Douglas, 10th earl of; Douglas, William Douglas, 1st earl of; Douglas, William Douglas, 8th earl of.

Douglas, William O(rville) (b. Oct. 16, 1898, Maine, Minn., U.S.—d. Jan. 19, 1980, Washington, D.C.), public official, legal educator, and associate justice of the U.S. Supreme Court best known for his consistent and outspoken defense of civil liberties. His 36½ years of service on the Court constituted the longest tenure in U.S. history.

The son of a Presbyterian minister, Douglas moved with his family first to California and then to Washington. His father died when William was a small child, and his mother then settled the family in Yakima, Wash. Although Douglas contracted polio as a youth, he escaped permanent paralysis and developed what would become a lifelong love of the outdoors through his self-imposed regimen of exercise during recovery.

After graduating from Whitman College (Walla Walla, Wash.) in 1920, Douglas briefly taught school. Resolving to enter law school, he worked his way across the country in 1922 and enrolled at Columbia University Law School, where he later edited the law review.

In 1925, Douglas was graduated second in his class from Columbia and shortly thereafter joined a Wall Street law firm to learn the intricacies of financial and corporate law. He left the firm one year later to teach law at Columbia, and a year after that he joined the law faculty at Yale, where he taught until 1936.

In 1934, after having worked with the Department of Commerce on bankruptcy studies, Douglas directed a study for the Securities and Exchange Commission (SEC) on the reorganization of bankrupt corporations. He became a member of the SEC in 1936, and in 1937 he was appointed chairman of the commission. In this capacity he engineered the reorganization of the nation's stock exchanges, instituted measures for the protection of small investors, and began government regulation of the sale of securities.

During his tenure with the SEC, Douglas became a friend and adviser of Pres. Franklin Roosevelt. When Justice Louis Brandeis retired from the Supreme Court in February 1939, Roosevelt nominated Douglas to fill the vacancy. Following his confirmation by the Senate, Douglas took his seat on April 17, 1939, becoming at 40 years of age the second youngest Supreme Court justice in U.S. history.

Although responsible for writing many of the opinions in complicated financial cases, Douglas became most famous for his pronouncements on civil liberties. Like his fellow justice and close friend Hugo Black, Douglas was an absolutist on the guarantees of freedom in the

Bill of Rights. He rejected government limitations on free speech, and he was an outspoken defender of an unfettered press. His total opposition to any form of censorship made him a frequent target for criticism from political conservatives and religious fundamentalists.

Douglas also strove to ensure the protection of the constitutional rights of the criminally suspect, and he took a leading part in the Court's decisions that curbed coerced confessions, buttressed the accused's right against self-incrimination, and strengthened prohibitions against illegal searches.

Felled by a stroke on Dec. 31, 1974, Douglas struggled to overcome its debilitating effects and returned briefly to the bench before retiring on Nov. 12, 1975. Throughout his judicial career Douglas remained a prolific writer, especially on conservation, history, politics, and foreign relations; his books include *Of Men and Mountains* (1950) and *A Wilderness Bill of Rights* (1965).

Douglas fir, any of about six species of coniferous evergreen timber trees comprising the genus *Pseudotsuga* of the family Pinaceae, native to western North America and eastern Asia. A Douglas fir has long, flat, spirally arranged needles that grow directly from the branch. Each yellow- or blue-green needle has a short stalk at the base and a grooved up-

Cone of a Douglas fir (*Pseudotsuga menziesii*)
Grant Heilman

per surface. Winter buds are brown, shiny, and pointed. The hanging, oblong cones have three-pointed bracts (outer cone scales). Cones mature in one season and retain their scales when they fall.

The North American tree commonly known as Douglas fir is *P. menziesii* (*P. douglasii* by some authorities). It has several forms, one with reflexed bracts, that sometimes are considered to be separate species. Douglas fir may grow to 75 m (250 feet) tall and 2.4 m in diameter. It is one of the best timber trees in North America, as well as a popular ornamental and Christmas tree, and is used for reforestation along the Pacific Coast. The first seeds are produced at about 25 years, with large crops every 5 to 7 years. The bigcone Douglas fir (*P. macrocarpa*), a smaller species important only for erosion control, bears cones 10 to 15 cm (about 4 to 6 inches) long.

Douglas-Home, Sir Alec, also called (1951–63) ALEXANDER FREDERICK DOUGLAS-HOME, 14TH EARL OF HOME, or (from 1974) ALEXANDER FREDERICK DOUGLAS-HOME, BARON HOME OF THE HIRSEL OF COLDSTREAM (b. July 2, 1903, London, Eng.—d. Oct. 9, 1995, The Hirsell, Coldstream, Berwickshire, Scot.), British foreign secretary from 1960 to 1963,

prime minister from Oct. 19, 1963, to Oct. 16, 1964, and, after the fall of his government, Conservative opposition spokesman in the House of Commons on foreign affairs. He was also foreign secretary from 1970 to 1974.

As Lord Dunglass, the courtesy title he held until he succeeded in 1951 to the earldom of Home, he sat in the House of Commons as a Unionist (1931–45, 1950–51). He served as parliamentary private secretary to Prime Minister Neville Chamberlain (1937–39), undersecretary of state for foreign affairs in Winston Churchill's "caretaker" government (May–July 1945), minister of state for Scotland (1951–55), secretary of state for Commonwealth relations (1955–60), deputy leader (1956–57) and leader (1957–60) of the House of Lords, and lord president of the council (1957–60) before his first term as foreign secretary. In October 1963 he disclaimed his peerages for life, took the name Sir Alec Douglas-Home, and succeeded Harold Macmillan as prime minister during a Conservative Party crisis, the most spectacular feature of which was an adultery scandal involving John Dennis Profumo, secretary of state for war from 1960 to 1963.

Admittedly having slight knowledge of economics, Sir Alec as prime minister was unable to improve the deteriorating British balance-of-payments situation. He antagonized numerous Conservatives by inducing the House of Commons to pass legislation against price-fixing. Both as foreign secretary and as prime minister, he gained U.S. approval for his firm anti-Communism. Throughout his ministry he was faced with the prospect of a forthcoming general election, which took place on Oct. 15, 1964, and brought a Conservative defeat. He was succeeded (July 1965) as party leader by the future prime minister Edward Heath. In December 1974 he was created a life peer, Baron Home of the Hirsell of Coldstream.

Douglas-Home
Keystone

In 1976 he published his autobiography, *The Way the Wind Blows*. He also published *Border Reflections: Chiefly on the Arts of Shooting and Fishing* (1979) and *Letters to a Grandson* (1983).

Douglas scale, either of two arbitrary series of numbers from 0 to 9, used separately or

in combination to define qualitatively the degree to which the ocean surface is disturbed by fresh waves (sea) generated by local winds, and by decaying waves, or swell, propagated from their distant wind sources (see Table). The scales were devised in 1921 by the British Navy captain H.P. Douglas and were adopted by the International Meteorological Conference in Copenhagen in 1929.

Douglass, Andrew Ellicott (b. July 5, 1867, Windsor, Vt., U.S.—d. March 20, 1962, Tucson, Ariz.), American astronomer and archaeologist who established the principles of dendrochronology (the dating and interpreting of past events by the analysis of tree rings). He coined the name of that study when, while working at the Lowell Observatory, Flagstaff, Ariz. (1894–1901), he began to collect tree specimens, believing that variations in the width of tree rings would show a connection between sunspot activity and the terrestrial climate and vegetation.

Douglass taught astronomy (from 1906) and dendrochronology (from 1936) at the University of Arizona and directed that university's Steward Observatory, Tucson (1918–38). Among his achievements in astronomy was the first photograph of the zodiacal light. He was also an authority in the study of Mars.

Douglass, Frederick, original name FREDERICK AUGUSTUS WASHINGTON BAILEY (b. Feb. 7, 1817, Tuckahoe, Md., U.S.—d. Feb. 20, 1895, Washington, D.C.), black American who was one of the most eminent human-rights leaders of the 19th century. His oratorical and literary brilliance thrust him into the forefront of the U.S. Abolition movement, and he became the first black citizen to hold high rank in the U.S. government.

Separated as an infant from his slave mother (he never knew his white father), Frederick lived with his grandmother on a Maryland plantation until, at the age of eight, his owner sent him to Baltimore to live as a house servant with the family of Hugh Auld, whose wife defied state law by teaching the boy to read. But Auld declared that learning would make him unfit for slavery, and Frederick was forced to continue his education surreptitiously with the aid of schoolboys in the street. Upon the death of his master, he was returned to the plantation as a field hand at 16. Later, he was hired out in Baltimore as a ship caulker. He tried to escape with three others in 1833, but the plot was discovered before they could get away. Five years later, however, he fled to New York City and then to New Bedford, Mass., where he worked as a labourer for three years, eluding slave hunters by changing his name to Douglass.

At a Nantucket, Mass., antislavery convention in 1841, Douglass was invited to describe his feelings and experiences under slavery. These extemporaneous remarks were so poignant and naturally eloquent that he was unexpectedly catapulted into a new career as agent for the Massachusetts Anti-Slavery Society. From then on, despite heckling and

mockery, insult, and violent personal attack, Douglass never flagged in his devotion to the Abolitionist cause.

To counter skeptics who doubted that such an articulate spokesman could ever have been a slave, Douglass felt impelled to write his autobiography in 1845, revised and completed in 1882 as *Life and Times of Frederick Douglass*. Douglass' account became a classic in American literature as well as a primary source about slavery from the bondsman's viewpoint. To avoid recapture by his former owner, whose name and location he had given in the narrative, Douglass left on a two-year speaking tour of Great Britain and Ireland. Abroad, Douglass helped to win many new friends for the Abolition Movement and to cement the bonds of humanitarian reform between the continents.

Douglass returned with funds to purchase his freedom and also to start his own antislavery newspaper, the *North Star* (later *Frederick Douglass's Paper*), which he published from

Frederick Douglass

1847 to 1860 at Rochester, N.Y. The Abolition leader William Lloyd Garrison disagreed with the need for a separate, black-oriented press, and the two men broke over this issue as well as over Douglass' support of political action to supplement moral suasion. Thus, after 1851 Douglass allied himself with the faction of the movement led by James G. Birney. He did not countenance violence, however, and specifically counselled against the raid on Harpers Ferry, Va. (October 1859).

During the Civil War (1861-65) he became a consultant to Pres. Abraham Lincoln, advocating that former slaves be armed for the North and that the war be made a direct confrontation against slavery. Throughout Reconstruction (1865-77), he fought for full civil rights for freedmen and vigorously supported the women's rights movement.

After Reconstruction, Douglass served as assistant secretary of the Santo Domingo Commission (1871), and in the District of Columbia he was marshal (1877-81) and recorder of deeds (1881-86); finally, he was appointed U.S. minister and consul general to Haiti (1889-91).

Douhet, Giulio (b. May 30, 1869, Caserta, Italy—d. Feb. 15, 1930, Rome), Italian army general and the father of strategic air power.

Trained as an artillery officer, from 1912 to 1915 Douhet served as commander of the Aeronautical Battalion, Italy's first aviation unit. Largely because of his efforts, the three-engine Caproni bomber was ready for use by the time Italy entered World War I. He soon grasped the potential of air power and at every opportunity expounded his theories. His severe criticism of the conduct of the war resulted in his court-martial, imprisonment, and retirement. But investigation of the Italian defeat at Caporetto in 1917 justified his criticisms; his conviction was reversed, and he was appointed head of the aviation service.

Douhet's most noted book is *Il dominio dell'aria* (1921; *The Command of the Air*, 1942). He challenged the violent opposition it aroused until strategic air power became an accepted part of military thinking. Although technological developments have made some of his ideas obsolete, his theory of the important role of strategic bombing in disorganizing and annihilating an enemy's war effort was incorporated into future military plans of Italy and the United States. He further advocated the creation of an independent air force, the reduction of land and sea forces, and the unification of the armed forces. Controversial though his ideas were, many were adopted, in part at least, by the major powers before and during World War II.

doulcemele (musical instrument): see dulcemeles.

Doulton ware, English pottery established in 1815 by John Doulton at Lambeth, London, in association with John Watts and known as Doulton and Watts. The company became Doulton and Co. (Ltd.) about 1858 and remained so until the factory closed in 1956.

Doulton was known chiefly for its utilitarian stoneware and earthenware until about 1871, when students of the Lambeth School of Art began decorating Doulton salt-glazed brown stoneware. The students' work may be considered not only a source of renewed interest in ornamental stoneware but also the first noteworthy example of artist-pottery in England. Hannah Barlow and her brother and sister, Arthur and Florence, along with Frank Butler, Emily Edwards, and George Tinworth were among the artists who worked in the Doulton studio. The practice was continued into the 20th century, and it led to the development of similar projects at other English potteries.

In about 1877-78 Doulton of Lambeth bought the earthenware factory of Pindar, Bourne and Company at Burslem, Staffordshire. The name was retained until 1882 when it was changed to Doulton and Company, Ltd. This Doulton enterprise became well known for its fine porcelains, which were especially successful in the United States and Canada. In 1901 the company was authorized by King Edward VII to market its products as Royal Doulton (the royal mark appeared in 1902). Since October 1955 the official name of the firm has been Doulton Fine China, Ltd. It was appointed supplier to Queen Elizabeth II in 1968.

doum nut, also spelled **DHOUM NUT**, the nut of the doum palm (*Hyphaene thebaica*), native to Upper Egypt, Sudan, Kenya, and Tanzania. Also called the gingerbread palm, the 15.2-metre (50-foot) tree has a slender trunk and smooth branches, each tipped with a rosette of small, stiff, green, fanlike leaves.

The flavour of the red-orange fruit is frequently likened to that of gingerbread. The nut is eaten raw, and the rind from the seeds is made into sweetmeats and molasses. The ground nuts are used to dress wounds. Vegetable ivory, the hard, white part of the nut, takes a high polish and is used as a substitute for ivory, especially in the manufacture of buttons. Leaves of the doum palm are used for cordage, mats, and inferior paper. Doum nuts have been found in 5,000-year-old Egyptian tombs.

Doumer, Paul (b. March 22, 1857, Aurillac, Fr.—d. May 6, 1932, Paris), the 13th president of the French Third Republic whose term was cut short by an assassin's bullet.

In 1889 Doumer was elected as a Radical deputy from the Yonne *département*, and his reputation as a fiscal expert led to his appointment (1895) as minister of finance in the Cabinet of Léon Bourgeois. Unsuccessful

in his efforts to introduce a national income tax, he was appointed governor general of Indochina the following year.

Doumer was one of the most active and, from the French point of view, effective gover-

Doumer, c. 1930

H. Roger-Vollet

nors general of Indochina. Unlike many of his predecessors and successors he occupied his post for a sustained period (1897-1902) and had clearly defined aims. His most important achievements were to strengthen the hold of the governor general over the administrators at the head of the various components of Indochina and to place the colonial economy on a sound basis. While this latter development was welcomed by the French, it involved rigorous imposition of taxes on the local population, which caused deep resentment.

Doumer returned to the Chamber of Deputies in 1902 and then moved to the Senate (1912) as representative of Corsica. In 1903 he wrote *L'Indochine française* and in 1906 *Le Livre de mes fils* ("The Book of My Sons"). From 1927 to 1931 he was president of the Senate and chairman of the important budget commission. In addition, he served as finance minister in the Briand cabinets of January 1921 to January 1922 and December 1925 to March 1926.

Doumer's election to the presidency on May 13, 1931, was popularly received and he successfully weathered ministerial crises caused by the deaths of André Maginot and Aristide Briand. He was fatally shot by a Russian anarchist, Pavel Gorgulov.

Doumergue, Gaston (b. Aug. 1, 1863, Aigues-Vives, Fr.—d. June 18, 1937, Aigues-Vives), French political figure whose term as 12th president of the Third Republic was marked by nearly constant political instability.

After service as an official in Indochina and Africa (1885-93), Doumergue was elected as a

Doumergue, c. 1923

H. Roger-Vollet—Haringue

Radical-Socialist member of the Chamber of Deputies from Nîmes (1893). In June 1902 he was appointed to the first of his 11 ministerial posts. In 1910 he was elected to the Senate. On Dec. 13, 1913, he formed his own Cabinet, and, although it collapsed within seven months, he remained in various ministerial positions until March 1917. He then returned to the Senate and was its president until his election to the presidency of the republic on June 13, 1924.

Doumergue's presidential victory came as a rebuff to the Cartel des Gauches, a coalition of leftist parties, which had just won a substantial parliamentary victory. Hence, his term was marked by constant ministerial problems—there were 15 different cabinets—as well as severe social tensions caused by the beginning of the Great Depression. In February 1934, three years after he left the presidency, Doumergue was called upon to form a new government, but his plans for a Union Nationale, a broad-based coalition of all parties, and constitutional reforms were unsuccessful. He resigned Nov. 8, 1934, and retired completely from political life.

Doura-Europus (ancient Syria): *see* Dura-Europus.

dourine, venereal disease of horses, caused by the protozoan *Trypanosoma equiperdum*. The disease, which involves paralysis, is incurable. Serum tests have largely eradicated it in advanced countries, where a positive test requires the destruction of the animal. Trypanosomiasis, also caused by *Trypanosoma*, is known in two forms, Chagas' disease and sleeping sickness (*qq.v.*).

Douris, also spelled DURIS (fl. early 5th century BC), Greek vase painter of the early Classical period, known for his fine draftsmanship and crisp, clear lines. He worked in both the red- and black-figure styles, and he decorated

"Jason Being Disgorged by a Dragon," interior of a kylix by Douris, c. 480–470 BC; in the Vatican Museum

By courtesy of the Vatican Museum

his vases with many themes. He frequently selected themes popular during the Archaic period, for example, the Golden Fleece, but reinterpreted them to make them more relevant to his time.

Douris was a prolific painter whose signature has been identified on about 40 vases. More than 200 vase paintings have been attributed to him; most are decorated in the red-figure style, though some are black-figure. (Red-figure style has red figures painted against a black glazed background; black-figure style is the opposite.) A cup depicting "Eos Embracing Her Dead Son Memnon" is frequently attributed to Douris. Other vessels that Douris is believed to have painted include a psykter (cooler) of "Drunken Silenus," an "Ajax and

Ulysses," and a "School Interior." It is possible that some of Douris' paintings may reflect the now lost monumental mural paintings of Classical Greece.

Douro River, Latin *DURIUS*, Spanish *RÍO DUERO*, Portuguese *RIO DOURO*, third longest river of the Iberian Peninsula, draining a catchment area of 30,539 square miles (79,096 square km). Rising in the Sierra de Urbión in Spain, the river crosses the Numantian Plateau in a pronounced bend and

Terraced hillside in Portugal above the Douro River
Ronny Jaques—Photo Researchers

flows generally westward for 556 miles (895 km) across Spain and northern Portugal to the Atlantic Ocean at Foz do Douro. As far as Aranda de Duero, Spain, it is narrowly confined by its banks; it then widens across the broad plains of Old Castile. Beyond Zamora the river narrows again, and when it reaches the border with Portugal (which it follows for 70 miles [113 km]), it plunges about 1,250 feet (380 m) within 30 miles (50 km) in a series of gorges and rapids. In Portugal, between Peso da Régua and Porto (Oporto), the river has considerable barge traffic, taking the wine from the port-wine area to Vila Nova de Gaia; from Pedorido to Porto there is some coal traffic. The river mouth is silted, and the artificial port of Leixões (erected in 1892 and further developed in 1916) has grown up to the north of the estuary.

The major tributaries of the Douro—the Esla, Pisuerga, and Arlanzón, all in Spain—flow from the wetter northern zone; the southern tributaries are less important.

Since the 1930s the Douro has been harnessed extensively for hydroelectric power and irrigation.

douroucoul (monkey): *see* durukuli.

Dousa, Janus: *see* Does, Johan van der.

dove, any of certain birds of the pigeon family, *Columbidae* (order *Columbiformes*). The names pigeon and dove are often used interchangeably. Although "dove" usually refers to the smaller, long-tailed members of the pigeon family, there are exceptions: the domestic pigeon, a rather typical pigeon, is frequently called the rock dove and is the bird portrayed and called the "dove of peace." The common names of these birds do not necessarily provide any information about their biological relationships. *See* domestic pigeon; pigeon.

Dove, Arthur G., in full **ARTHUR GARFIELD DOVE** (b. Aug. 2, 1880, Canandaigua, N.Y., U.S.—d. Nov. 23, 1946, Huntingdon, N.Y.),

American painter, one of the earliest nonobjective artists.

Dove graduated from Cornell University, Ithaca, N.Y., in 1903. He began his career as a magazine illustrator, but in 1907–08 he traveled to Paris to study. While there he was influenced by Impressionism, the work of Paul Cézanne, and Fauvism, and he exhibited twice in the Salon d'Automne. In 1909 he returned to the United States, met Alfred Stieglitz, and—together with John Marin and Georgia O'Keeffe—became an artist whom Stieglitz championed at 291, his gallery in New York City. Dove exhibited there in 1910, by which time he had embraced abstract art.

Dove's art reflected his belief that colour and form are instruments with which to express the essence beneath the physical exterior of things; his shapes are typically amorphous, his colours muted. In "Foghorns," for example, he used size-graduated shapes and gradations of hue to express visually the sound of foghorns. Despite their nonobjective character, his paintings often suggest the curvilinear qualities of landscape and the forms of nature. Dove also created many fine, ironic collages, such as "Goin' Fishin'," made of a variety of materials.

"Goin' Fishin'," collage of bamboo, denim shirt sleeves, bark, and pieces of wood on wood support by Arthur Dove, 1925; in The Phillips Collection, Washington, D.C.

© The Phillips Collection, Washington, D.C.

He had little financial success. In the 1920s he separated from his wife and child and concentrated on his painting. He found a patron in 1922 (Duncan Phillips, founder of the Phillips Collection in Washington, D.C.) but never found solid financial ground. He became ill in the late 1930s, but he continued to paint and produced what most critics consider to be his best work in the 1940s.

dove tree, also called **HANDKERCHIEF TREE** (species *Davidia involucrata*), small flowering tree, constituting the family *Davidaceae*, with showy creamy bracts (modified leaves) sur-

Dove tree (*Davidia involucrata*)

rounding the flowers. Native to southwestern China, it has been introduced elsewhere. Pyramidal in shape, with large bright-green leaves, it is especially impressive in bloom. Each terminal flower head is about 2 centimetres ($\frac{3}{4}$ inch) across and is subtended by two large bracts, one up to 16 cm long and the other half as long.

dovekie, also called **LITTLE AUK** (*Alle alle*), small, black and white seabird of the North Atlantic. The dovekie belongs to the family Alcidae (order Charadriiformes). It is about 20 centimetres (8 inches) long, with a short bill.

Dovekie (*Alle alle*) with winter plumage
Painting by H. Jon Janosik

Its legs and wings are short, and its feet are webbed. It is a proficient diver, feeding on fish, mollusks, and crustaceans. Dovekies breed on rocky coasts and islands of the Arctic Ocean, from Greenland to Novaya Zemlya, Russia. They nest in large colonies, each breeding pair laying a single egg in a rock cranny on a hillside, or, on peaty ground, in a burrow.

Dover, district, eastern part of the county of Kent, England, on the Strait of Dover. Its area is 120 sq mi (312 sq km). The history and economy of the district reflect its location as the part of England closest to France. Through the district pass major routes from London to Belgium and France. The old ports of Sandwich, Deal, and Dover are the principal towns. White chalk cliffs line much of the coast. Pop. (1998 est.) 108,700.

Dover, town and seaport on the Strait of Dover, county of Kent, England, situated at the mouth of a valley in the chalk uplands that form the famous white cliffs.

A pre-Roman settlement existed on the site, and, as Dubris, the place was important for Roman traffic with the European mainland. In the 4th century AD it was guarded by a fort as part of the defenses of the Saxon Shore. The castle, 375 ft (114 m) above sea level and from which on a clear day the coast of France can be seen, dominates the town below. Within its precincts are a Roman lighthouse, the ancient fortress Church of St. Mary in Castro, remains of the Saxon stronghold, and the massive Norman keep. During the 11th century it was made one of the Cinque Ports (*q.v.*). Dover claims to be a Saxon borough by "prescription," without a formal charter of incorporation.

During World War II the town was shelled from France and bombed from the air, but the shattered seafont was subsequently redeveloped after the war. Dover is the foremost passenger port in the United Kingdom, with a harbour of more than 600 ac (240 ha); it is the principal cross-Channel ferry port. Some light industries have become important. Pop. (1991) 34,179.

Dover, city, capital (1777) of Delaware, U.S., city, seat of Kent county, in the east central portion of the state on the St. Jones River. It was laid out in 1717 as the site for a county courthouse and jail on the order (1683) of William Penn and named for the English city. Colonial buildings clustered around the Green include the Old State House (rebuilt 1787–92), which served as the Capitol building until 1933 when the main state offices were trans-

Legislative Hall, keystone of the capitol buildings group, Dover, Del.
Milt and Joan Mann from CameraMann

ferred to nearby Legislative Hall. King Charles II's original royal grant and William Penn's deeds to Delaware (1682) from James, duke of York, are displayed in the Hall of Records. The mansion (1740) of John Dickinson, "penman of the Revolution," is preserved, and the Delaware State Museum occupies a Presbyterian church (1790). Dover is a farm trade centre with some light industries. It is the seat of Delaware State College (1891) and Wesley College (1873). Dover Air Force Base, established during World War II, is now the principal air cargo terminal for the Military Airlift Command. Inc. town, 1829; city, 1929. Pop. (2000) 32,135.

Dover, city, seat (1769) of Strafford county, southeastern New Hampshire, U.S., at the falls (a 33-ft [10-m] drop) of the Coheco River near its junction with the Piscataqua River, just northwest of Portsmouth. Originally settled in 1623 by fishermen and traders, it was first known as Bristol. A second settlement was made at nearby Dover Neck, or Point, in 1633. The town was an independent entity before 1642, when it voluntarily submitted to the jurisdiction of Massachusetts. Dover was a target for Indian attacks from about 1675 to 1725, the worst occurring on June 28, 1689. The town developed around the Point and its shipbuilding interests, but as manufacturing grew in the 18th and 19th centuries the centre gradually shifted northward. Diversified industries now include the manufacture of textiles, shoes, chemicals, plastics, and electronic equipment. The Woodman Institute has natural science and colonial exhibits. Inc. city, 1855. Pop. (2000) city, 26,884.

Dover, Strait of, French **PAS DE CALAIS**, Latin **GALLICUM FRETUM**, a narrow water passage separating England (northwest) from France (southeast) and connecting the English Channel (southwest) with the North Sea (northeast). The strait is 18 to 25 mi (30 to 40 km) wide, and the depth ranges from 120 to

Strait of Dover with the White Cliffs
Ace Williams—Shostal

180 ft (35 to 55 m). Until the comparatively recent geologic past (c. 5000 BC), the strait was an exposed river valley, thus making England an extension of the European continent. Because of the prevailing winds, the main flow of water through the strait is from the southwest, but a persistent northeast wind can reverse the current. The White Cliffs on the British side, composed of soft chalk, are receding due to erosion. Although it is one of the world's

busiest seaways, a strict system of traffic lanes and navigation information became mandatory only in 1977. The chief ports include Dover and Folkestone (England) and Calais and Boulogne (France). Much of the regular passenger service is carried by hovercraft. A rail-tunnel project across the bottom of the strait, first proposed in 1856, is again under consideration.

The Strait of Dover was the scene of several historic naval battles, notably the first major repulse by the English of the Spanish Armada (1588). During World War I, Boulogne was a major army base, and Dover was the headquarters for the "Dover patrol," which protected shipping in the strait. In 1940, the Allied troops evacuating from Dunkirk (Dunkerque, Fr.) crossed the strait to Dover. The name Dover originally meant "the waters" or "the stream."

Dover, Treaty of (1670), pact by which Charles II of England promised to support French policy in Europe in return for a French subsidy that would free him from financial dependence on Parliament.

There were actually two treaties of Dover in 1670: one, which was secret (and known to only two of Charles's councillors) was concerned with the conversion of England to the Roman Catholic faith, which was favoured by Charles II; and the other, which was formal, was concerned with an Anglo-French military and naval alliance designed to subjugate the United Provinces of the Netherlands, which was desired by Louis XIV. The secret treaty—in the negotiation of which Charles's sister Henrietta Anna, duchesse d'Orléans, was deeply involved—was concluded on June 1 (May 22, old style). By it, Charles II was to receive £200,000 in money and the support of 6,000 French troops, if needed, so that he might declare himself a Roman Catholic, and a further £300,000 a year to enable him to join a war against the Dutch. Among other clauses it was stipulated that England would support any claims that Louis might get to the Spanish succession. To allay suspicion, the formal treaty was concluded through the ordinary diplomatic channels on December 31 (December 21, old style), omitting all mention of religion.

The conversion clause never came into effect, for Louis XIV was really interested only in war, and Charles II's ambition was not so much the restoration of the Catholic religion as the establishment of the monarchical power that he thought Catholicism would secure. Charles came to promote that religion instead by a policy of religious toleration.

Dovre Mountains, Norwegian **DOVREFJELL**, range in south central Norway. Extending about 100 mi (160 km) from east to west and about 40 mi from north to south, the range is centred about 70 mi southeast of the town of Kristiansund. Composed mainly of layered metamorphic rocks (gneiss and schist), the mountains cover parts of the Sør-Trøndelag, Hedmark, Møre og Romsdal, and Oppland fylker (counties). The Dovre Mountains are bounded on the west by Romsdals Fjord, on the south by Gudbrands Valley, on the southeast by the Rondane Mountains, on the east by Øster Valley, and on the north by the Trollheimen Mountains. The highest peak is Snø Mountain (7,500 ft [2,286 m]). The Dovre Mountains are traversed from south to north by the main rail and by road links between Oslo and Trondheim. Some of the peaks are centres of winter sports activities.

Dovzhenko, Aleksandr (Petrovich) (b. Sept. 11 [Aug. 30, old style], 1894, Sosnitsy, Ukraine, Russia—d. Nov. 26, 1956, Moscow), a motion-picture director who brought

international recognition to the Soviet film industry during the 1930s. Emotional intensity and mystical symbolism often took precedence over narrative structure in his films,

Dovzhenko
Tass—Sovfoto

many of which concerned the Russian Civil War (1918–20) and the collectivization period (late 1920s to early '30s).

Born to Ukrainian peasants, Dovzhenko graduated from teachers college and became a political cartoonist for a Ukrainian newspaper. He also studied painting under German Expressionist Erich Heckel. He began his film career in 1926, making his directorial debut with the short subject *Yagodki lyubvi* (1926; "The Fruits of Love"). *Zvenigora* (1928), his first important film, is a lyrical history of the Ukrainian people from their Viking origins to the Russian Revolution; *Arsenal* (1929) deals with a hero of allegorical stature confronted with the forces of the Revolution; *Zemlya* (1930; *The Earth*) interprets in sensitive visual symbolism the almost mystical closeness of the Ukrainian peasant to his land. Other well-known films were *Ivan* (1932); *Aerograd* (also known as *Frontier*, 1935), dealing with the establishment of an airfield in a remote Siberian outpost; *Shchors* (1939), the story of a Ukrainian revolutionary commander, which won Dovzhenko the first of two Stalin prizes (1941, 1949); and *Michurin* (1946; *Life in Blossom*).

Dow, Charles Henry (b. Nov. 6, 1851, Sterling, Conn., U.S.—d. Dec. 4, 1902, Brooklyn, N.Y.), American journalist who cofounded Dow Jones & Company, a financial news service, and *The Wall Street Journal*. His original contributions include the compilation in 1884 of the first average of selected U.S. stock prices that, with some modification, developed into what are known as the Dow Jones averages.

In his twenties Dow took up journalism, moving to New York City in 1880 to become a reporter for a financial news service. In 1882 Dow and Edward D. Jones (1856–1920) founded Dow Jones & Company, a firm that delivered bulletins, called "flimsies,"

Charles Henry Dow

By courtesy of Dow Jones & Company, Inc.

or "slips," to Wall Street financial houses by messenger. The last delivery of the day included a news sheet that was the forerunner of *The Wall Street Journal*, which was first published July 8, 1889. Dow made his reputation as a financial expert when he was the paper's first editor (1889–1902), and his writings for it form the basis for the "Dow theory" in market analysis. He was a member of the New York Stock Exchange (1885–91) and a partner in the brokerage firm of Goodbody, Glyn & Dow.

Dow, Herbert H., in full HERBERT HENRY DOW (b. Feb. 26, 1866, Belleville, Ont., Can.—d. Oct. 15, 1930, Rochester, Minn., U.S.), pioneer in the American chemical industry and founder of the Dow Chemical Company.

Dow first became interested in brines (concentrated solutions of salts and water) while attending Case School of Applied Science (now Case Western Reserve University) in Cleveland (B.S.; 1888). His analysis of brines from several sites revealed that those of Canton, Ohio, and Midland, Mich., were rich in bromine. He developed and patented electrolytic methods for extracting bromine from brine and in 1890 organized the Midland Chemical Company. The Dow process was remarkable in that it did not result in a salt by-product and that it operated on comparatively little fuel, which was provided by waste from the then-thriving Michigan lumber industry. The process also involved the first commercially successful use of the direct-current generator in the American chemical industry.

In 1895 Dow founded the Dow Process Company to electrolyze brine for chlorine (producing caustic soda and sodium hypochlorite) at Navarre, Ohio, soon moving the company to Midland and creating the Dow Chemical Company (1897) to absorb the Midland Chemical and Dow Process. Dow's chlorine products found application in insecticides and (through the electrolysis of magnesium chloride) stucco and magnesium metal. He further introduced automatic processing to produce magnesium sulfate (Epsom salts) from ocean brines, produced the first synthetic indigo process in the Western Hemisphere (1916), and was the first American producer of iodine (which he also extracted from brine). He eventually was granted some 65 patents as his company became one of the world's leading chemical manufacturers.

Dow, Neal (b. March 20, 1804, Portland, Me., U.S.—d. Oct. 2, 1897, Portland), American politician and temperance advocate whose Maine Law of 1851 presaged national prohibition in the United States.

His Quaker parents and his own observations as Portland city overseer of the poor, as well as the excess of drunkenness that was then commonplace, influenced his attitude toward liquor. He organized the Maine Temperance Union in 1838. As mayor of Portland (1851–58), he wrote a state prohibition law and secured its passage (June 2, 1851) to replace a weaker statute of 1846, for which he also had been partly responsible. After serving in the American Civil War he resumed his temperance activities and in 1880 ran for president of the United States as the Prohibition Party candidate. His autobiography, *The Reminiscences of Neal Dow, Recollections of Eighty Years*, was published posthumously in 1898.

Dow Chemical Company, leading American petrochemical company that manufactures chemicals, pharmaceuticals, plastics, consumer goods, paint, and many other products for industrial and home use. Headquarters are in Midland, Mich.

Dow Chemical Company was founded in 1897 by chemist Herbert H. Dow of Midland to supplement the Midland Chemical Company (1890) and Dow Process Company (1895). Created in part because Dow required

a bleach plant to use the wastes from the bromine extraction processes performed by Midland Chemical, the new company also began extracting other chemicals such as chlorides, magnesium, and calcium from nearby Michigan's plentiful brine deposits. In 1900 Dow Chemical was incorporated, combining all of Dow's Midland properties.

While the vast majority of Dow products are benign, a number have been the subject of adverse public attention and lawsuits. The company made mustard gas, a toxic blistering agent used in chemical warfare, during World War I. During the Vietnam War, it produced napalm, a jellied incendiary reported to have been used indiscriminately against civilians and soldiers. Dow also was one of several makers of Agent Orange, an herbicide containing the toxic substance dioxin (*q.v.*). In 1995 Dow Corning (a joint venture of Dow Chemical and Corning, Inc.) declared bankruptcy following an overwhelming number of lawsuits that were instituted when it was revealed that silicone breast implants manufactured by Dow Corning and other companies had leaked and were held to have caused a variety of health problems.

Dow Chemical Company operates major plants in the United States and abroad, operates subsidiaries on every continent, and markets its products worldwide. In addition to producing such familiar consumer products as aspirin, plastic wrap, and Styrofoam plastic foam, it manufactures a broad range of industrial chemicals and metals, plastics and packaging materials, and bioproducts, and it is the most diversified petrochemical company in the world.

Dow Jones average, stock price average computed by Dow Jones & Company. The averages are among the most commonly used indicators of general trends in the prices of stocks and bonds in the United States. Dow Jones & Company, a financial news publisher founded by Charles Henry Dow and Edward D. Jones, began computing a daily industrials average in 1897, using a list of 12 stocks and dividing their total price by 12. The list of stocks has since been broadened, and the divisor has been adjusted to compensate for stock splits, stock substitutions, and significant dividend changes. Thus, the averages are no longer arithmetic means but are averages in the sense of indicators of general market price trends. The most commonly quoted is the industrial average, based on the prices of 30 selected industrial stocks. The other Dow Jones averages published include one based on 20 transportation stocks, one based on 15 utility stocks, a composite based on all 65 stocks, and several bond averages.

Dowa Highlands, also called CHITEMBWE-MWERA HIGHLANDS, central Malaŵi, rectangular formation covering an area of about 360 square miles (930 sq km); they comprise rolling hills crowned by high ridges including the heights of Dowa (5,571 feet [1,698 m]) and Ntchisi peaks. The highlands are bounded on three sides by steep slopes, forming the Eastern (Great) Rift Valley wall to the east and overlooking the Bua and Lilongwe river valleys to the north and south, respectively. Their western limit is marked by a series of hills leading onto the central plains. Mountain streams form a radial drainage pattern contributing to the Lilongwe and Bua rivers and Lake Nyasa; the eastern streams have periods of heavy flood. The highland's red loam soils support woodland.

Dowager, Empress: see Tz'u-hsi.

Dowden, Edward (b. May 3, 1843, Cork, County Cork, Ire.—d. April 4, 1913, Dublin), Irish critic, biographer, and poet, outstanding for his work on Shakespeare. Educated at Queen's College, Cork, and Trinity College, Dublin, Dowden became professor of English

Dowden
BBC Hulton Picture Library

literature at Trinity in 1867 and lectured at Oxford (1890–93) and Cambridge (1893–96). His *Shakspere: A Critical Study of His Mind and Art* (1875) was the first book in English to attempt a unified and rounded picture of Shakespeare's development as an artist, studying him in terms of successive periods.

In addition to numerous other works on Shakespeare, Dowden is remembered for his *Life of Shelley* (1886). He also was among the first to appreciate Walt Whitman and became his good friend.

Dowding, Hugh Caswall Tremeneere Dowding, 1st Baron (b. April 24, 1882, Moffat, Dumfriesshire, Scot.—d. Feb. 15, 1970, Tunbridge Wells, Kent, Eng.), British air chief marshal and head of Fighter Command dur-

Dowding
Camera Press

ing the Battle of Britain (1940) in World War II; he was largely responsible for defeating the German Air Force in its attempt to gain control of British skies in preparation for a German invasion of England.

A squadron commander in the Royal Flying Corps in World War I, Dowding remained in the new Royal Air Force. After serving in command, staff, and training positions in Britain and Asia, he became chief of the newly created Fighter Command in 1936. He vigorously promoted the development of radar and the Spitfire and Hurricane fighters that contributed significantly to the defeat of the Luftwaffe during the Battle of Britain. Although the Fighter Command was outnumbered, Dowding's strategic and tactical skill enabled it to retain air superiority and thwart Germany's aims. He retired in November 1942 and was created baron the next year.

Dowie, John Alexander (b. May 25, 1847, Edinburgh—d. March 9, 1907, City of Zion, Ill., U.S.), U.S. evangelist and faith healer who founded the Christian Catholic Church and the City of Zion.

Dowie moved with his family to Australia as a boy but returned to Edinburgh to study theology. He entered the Congregational ministry in 1870 as a pastor in Alma, Australia, and spent the next several years campaigning against the use of tobacco and alcohol. From a personal experience of healing he developed an interest in spiritual healing and eventually

founded the International Divine Healing Association.

In 1888 he went to the U.S. After receiving little attention in San Francisco, he settled in Chicago. There he became increasingly successful as an evangelist and healer and won every one of nearly a hundred suits brought against him by doctors and clergymen who opposed his practices. In 1896 he founded the Christian Catholic Church, which emphasized spiritual healing but otherwise differed little from the more millennialist of the Protestant churches. In 1901 he established the City of Zion on the shore of Lake Michigan, about 40 miles north of Chicago, with about 5,000 of his followers. In the same year he proclaimed himself Elijah the Restorer and, later, First Apostle of the church. He ruled the community as a theocracy, forbade physicians' offices, dance halls, theatres, drugstores, and smoking and drinking. Various industries were begun and the town prospered, with Dowie in sole control of the businesses. Zion's commercial success was increasingly jeopardized, however, by Dowie's several expensive and futile trips, first to New York to convert the city in 1903 and next to Mexico to establish the "Zion Paradise Plantation." Opposition to his fiscal irresponsibility (and to alleged polygyny) led to his removal in 1906 and his replacement by Wilbur Voliva, a trusted friend whom he had earlier named temporary head of the church.

dowitcher, any of three species of shorebirds belonging to the genus *Limnodromus*, family Scolopacidae. The dowitcher has a chunky appearance and a long bill like a snipe and, in breeding plumage, has reddish underparts, giving rise to the alternative names red-breasted snipe and robin snipe (given also to the knot). It has a white rump and lower back.

Dowitchers flock on mudflats or sandbars; they fly in tight formations and, after landing, pause awhile before spreading out to feed. They nest in bogs from northeastern Siberia to Hudson's Bay and winter on coasts from the southern U.S. to northern South America. The

Short-billed dowitcher (*Limnodromus griseus*)
A. A. Allen—Bird Photographs, Inc.

long-billed dowitcher (*L. scolopaceus*), about 30 centimetres (12 inches) long including the bill, has a more northwesterly breeding range than the short-billed dowitcher (*L. griseus*), which is about the same size except for the bill. There is also an Asian species, called the Asiatic dowitcher (*L. semipalmatus*).

Dowlaiswaram, town, East Godāvāri district, northeastern Andhra Pradesh state, southern India, on the Godāvāri River Delta. Dowlaiswaram is located at the source of the great delta, and a dam 2 mi (3.2 km) long crosses the river at this point, supplying canals that irrigate 1,000,000 ac (400,000 ha). Rice fields, gardens, and villages are scattered over the deltaic region that surrounds the mainly agricultural town. Pop. (1991) 35,357.

Dowland, John (b. 1562/63, County Dublin, Ire., or Westminster, London—d. Jan. 21, 1626, London), English composer, virtuoso

lutenist, and skilled singer, one of the most famous musicians of his time.

Nothing is known of Dowland's childhood, but in 1580 he went to Paris as a "servant" to Sir Henry Cobham, the ambassador to the French court. In 1588 he received a bachelor of music degree from Oxford, and one from Cambridge before 1597. His conversion to Roman Catholicism, he believed, caused his rejection for a post as a court lutenist in 1594. After that disappointment he left England to travel on the Continent. He visited the Duke of Brunswick at Wolfenbüttel and the Landgrave of Hesse at Kassel and was received at both courts with esteem. His travels also took him to Nürnberg, Florence, Genoa, and Venice; in 1597 he returned to England.

In 1598 Dowland became lutenist to Christian IV of Denmark, but he was dismissed for unsatisfactory conduct in 1606. Between 1609 and 1612 he entered the service of Theophilus, Lord Howard de Walden, and in 1612 he was appointed one of the "musicians for the lutes" to James I.

Working during a time of musical transition, Dowland, though a respecter of tradition, absorbed many of the new ideas he encountered on the Continent. His 88 lute songs (printed 1597–1612) particularly reflect those influences. The early songs are presented with an alternative version for four voices. Although melodically enchanting, they show simple strophic settings, often in dance forms, with an almost complete absence of chromaticism. Later, in such through-composed songs as "In darkness let me dwell" (1610), "From Silent Night," and "Lasso vita mia" (1612), the Italian declamatory style, chromaticism, and dissonance are introduced; no alternative four-voice versions are given.

Dowland composed about 90 works for solo lute; many are dance forms, often with highly elaborate divisions to the repeats. His famous *Lachrimae, or Seaven Teares Figured in Seaven Passionate Pavans* (1604), became one of the most widely known compositions of the time. In his chromatic fantasies, the finest of which are "Forlorne Hope fancye" and "Farewell," he developed this form to a height of intensity unequalled by any other writer for the Renaissance lute. His compositions also include several psalm harmonizations and sacred songs printed in contemporary music books.

Down, former (until 1973) county, eastern Northern Ireland. It was bounded by Belfast Lough (inlet of the sea; north), the Irish Sea (east), Carlingford Lough (south), former County Armagh (west), and former County Antrim (northwest).

Down had an area of 952 sq mi (2,466 sq km), and it had three areas of high ground. In the south, the Mourne Mountains (Slieve Donard, 2,796 ft [852 m]) are composed of Eocene (38,000,000-year-old) granite; and in the centre are the Caledonian granite mountains of Ballynahinch (Slieve Croob, 1,755 ft). The land falls westward to the Newry Basin and the River Bann and eastward to the Ards Peninsula, enclosing Strangford Lough (inlet of the sea), a large tidal inlet. A belt of glacially deposited ovoid hills (drumlins) extend westward from former central County Down. The basic geology is Silurian, with much slate and sandstone. The climate is temperate, rainfall varying from 65 in. (1,650 mm) a year in the Mournes to less than 35 in. in the east and north. Although soils of the southern slopes in the north are very fertile, a shallow stony loam predominates.

Evidence of prehistoric settlement is found in the Giant's Ring, south of Belfast. There a cromlech, or circle of stones, stands enclosed by a broad rampart; and near Newcastle there

is a well-preserved souterrain, or underground chamber. At Saul, St. Patrick began his mission in Ireland (AD 432), and a monastic school flourished at Bangor from the 6th century. The saint's well and bath houses are preserved at Struell near Downpatrick, and a boulder marks his reputed grave in the grounds of Downpatrick Cathedral. Dromore is the ancient ecclesiastical capital of Down. In the late 12th century, Down was invaded by the Anglo-Norman John de Courci; many of the mounds forming the bases of his forts remain. Numerous castles fringe the eastern part of the county (e.g., a Norman castle of Dundrum and Jordan's Castle at Ardglass). Although English influence declined in the late Middle Ages, it lingered on the peninsula of Lecale, between Dundrum and Downpatrick. In later Tudor times, parts of Down were colonized by English and Scottish adventurers; and, though the county was not included in the Plantation of Ulster scheme during the reign of James I, there was a large influx of Scottish colonists in the 17th century. In the 1973 administrative reorganization of Northern Ireland, the county was divided into the districts of Banbridge, Down, Ards, and North Down, and portions of Castlereagh, Lisburn, Craigavon, and Newry and Mourne districts.

Down, IRISH AN DÚN, district, Northern Ireland. Formerly within County Down, Down was established in 1973 as a district covering 249 square miles (646 square km) on Northern Ireland's eastern coast, fronting Strangford Lough (inlet of the sea) and the Irish Sea. It is bordered by the districts of Ards to the north; Castlereagh, Lisburn, and Banbridge to the west; and Newry and Mourne to the south. Extreme southern and western Down is mountainous; the dome-shaped Mourne Mountains reach an elevation of 2,789 feet (850 m) at Slieve Donard on the Down-Newry and Mourne border. Most of the district is covered by clusters of drumlins (oval mounds of glacial till). The area was invaded by the Anglo-Norman John de Courci in the late 12th century, and the town of Downpatrick was his stronghold until 1203. The Downpatrick (Protestant) Cathedral is reputedly built over the burial site of St. Patrick, who began his mission in Ireland (AD 432) in the nearby village of Saul.

Down is a rich agricultural district; the chief crops are oats, barley, wheat, and hay. Livestock raising (sheep and pigs) is also important. Downpatrick is the district's market and administrative seat and has some textile industry, while Ballynahinch, located farther west, has agricultural machinery and metal-fabrication industries. Newcastle in the south and Killyleagh in the east are popular seaside resorts. Tollymore Park, about 1,200 acres (500 hectares) of forest on the slopes of the Mourne Mountains in southern Down, was the first such park established in Northern Ireland (1955). Pop. (1985 est.) 55,400.

Down syndrome, also called DOWN'S SYNDROME, TRISOMY 21, or (formerly) MONGOLISM, congenital disorder caused by an extra chromosome on the chromosome 21 pair, thus giving the person a total of 47 chromosomes rather than the normal 46. Persons born with Down syndrome are characterized by several of the following: broad, flat face; short neck; up-slanted eyes, sometimes with an inner epicanthal fold; low-set ears; small nose and enlarged tongue and lips; sloping underchin; poor muscle tone; mental retardation; heart or kidney malformations or both; and abnormal dermal ridge patterns on fingers, palms, and soles. The mental retardation seen in persons with Down syndrome is usually moderate, though in some it may be mild or severe. Congenital heart disease is found in

Teenager with Down syndrome

© Bruce Roberts—Photo Researchers

about 40 percent of people with Down syndrome.

Most persons with Down syndrome have one excess chromosome associated with the chromosome 21 pair—a condition known as trisomy. Almost all individuals with Down syndrome have this trisomy, but a small number (perhaps 4 percent) have an abnormality called translocation, in which the extra chromosome in the 21 pair breaks off and attaches itself to another chromosome. The cause of the chromosomal abnormalities in Down syndrome remains unknown.

Down syndrome occurs in about 1 in every 800 live births. The incidence of the disorder increases markedly in the offspring of women over the age of 35. This is illustrated by the fact that Down syndrome's incidence in the offspring of young women is only about 1 in 1,000, while its incidence in those of women over age 40 is about 1 in 40. Down syndrome can be diagnosed prenatally by the presence of the abnormal chromosome in samples of fetal cells taken from the amniotic fluid.
